Basics on Locally compact Hausdorff spaces

(Refer Slide Time: 00:16)

Basic facts on locally compact Hausdorff spaces:

Let X be a locally compact Hausdorff space.

Thm. (1): If $x \in X$ has an open nbd. U , then \exists an open nbd. V of x such that $\overline{V} \subseteq U$. [Small compact nbd.].

Thm. (2): [Urysohn's Lemma] Given a compact set $K \subseteq X$ and an open set $V \supseteq K$, there exists a continuous $f: X \rightarrow [0, 1]$ such that:

- (i) $\text{supp}(f)$ is compact and lies in V .
- (ii) $f \equiv 1$ on K and $f \equiv 0$ outside V (or V^c).

So let us consider some basic facts on locally compact Hausdorff spaces of course we need Hausdorffness to have some nice analytic properties their existence of unique limits and so on. So we will consider those topological spaces which enjoy both local compactness as well as Hausdorff property. So if you start with a locally compact Hausdorff space X then the first theorem space that if x is a point in X then it has an open neighborhood U then there exist an open neighborhood V of x such that \overline{V} sits inside U .

So this is about small compact neighborhood existence of small compact neighborhoods meaning that no matter how small this open neighborhood U is there is something smaller V is something smaller which contains whose closure is contained in U . So this is the first used nice theorem that we shall need and the second one is a very important result in topology and this is called Urysohn's lemma even it is called lemma.

I will state it as a theorem then it is quite important and this Urysohn's lemma states that given a compact set K in X and an open set V which contains K . So open set V containing K there exist a continuous function f from X to \mathbb{C} such that the first property is that the support of f is compact and lies in V meaning that support of f is subset of V . And secondly f is identically equal to 1 on K and f is 0 outside V meaning on V complement is 0.

So Urysohn's lemma guarantees the existence of such a function on locally compact Hausdorff spaces actually here we can actually take the range to be 0, 1 rather than the whole complex numbers because f only takes value between 0 and 1. So we will use Urysohn's Lemma to create what are called partitions of unity.

(Refer Side Time: 04:00)

Thm. [Partition of unity]: Let X be a LCH space,
 V_1, V_2, \dots, V_n are open in X and K is compact in X s.t.
 $K \subseteq \bigcup_{i=1}^n V_i$
 Then there exist fun. $\varphi_i \ll V_i$ such that
 for all $x \in K$, we have $\sum_{i=1}^n \varphi_i(x) = 1$ and $\text{supp}(\varphi_i) \subseteq V_i$.
 $\varphi_i \in C(X), 0 \leq \varphi_i \leq 1$
 ↑
 partition of unity.
 $\{\varphi_i\}_{i=1}^n$ is called a partition of unity subordinate to $\{V_i\}_{i=1}^n$.

So before I go to the partition of the unity result let us fix some notation so we will see that we will write that $K \ll f$ let me call it less than f . So this will mean that K is compact f is a continuous function with compact support X such that it lies between the range of f lies between 0 and 1 and then finally that f is identically equal to 1 on K . So this is the notation in this case a second notation that we will use is $f \ll V$ and this will mean that V is an open set f is still continuous function with compact support with values between 0 and 1.

And that support of f is contained inside V so this means that f is identically equals to 0 on V complement. So in terms of the notation Urysohn's lemma with this notation states that given K compact sitting inside V open this is compact and this is open, there exist a continuous function

with compact support such that k is the sub set of, f less than f is less than v . So I am putting together these 2 parts of the notation and this means that f as range between 0 and 1 and f is 1 on k and f is 0 on k and f is 0 on the complement of v .

Note that this is also same as saying that this also means that we have an inequality that we have point wise inequality with the indicative function of the compact set k is less than or equal to f which is less than or equal to the indicative function of v . So we are trying to sandwich a continuous function in between the indicative function of a compact set and the indicative function of an open set. So let us see the statement of partition of unity theorem.

It says that on a locally compact Hausdorff space x if we have a finite collection of open sets v_1, v_2, v_n these are all open in x and if we have a compact set k is compact which is contained in the union of these V_i 's. Then there exist functions Φ_i less than V_i remember that these means that support of first that Φ_i is a continuous function with compact support with values between 0 and 1 and support of Φ_i is a sub set of V_i .

So there exist for each i for function continuous function of compact support Φ_i whose support lies inside V_i and such that for any x in this set compact set k we have that the sum of Φ_i from 1 to n evaluated at x sums up to 1. And this is called a partition of unity because you are waking up this function which is identically 1 on k in to parts which as support inside compact inside V_i . So this collection $\Phi_i, i = 1$ to, n is called a partition of unity subordinate to the collection $V_i, i = 1$ to, n .

So let us try to see how to prove this partition of unity existence of this partition of unity using the Urysohn's Lemma.

(Refer Slide Time: 10:15)

PP 8 From theorem (1), for each $x \in K$, there exists
an open set W_x of x s.t. $W_x \subseteq \bar{W}_x \subseteq V_i$ for some i .

Take the open cover $\bigcup_{x \in K} W_x \supseteq K$.

\Rightarrow By compactness, $\exists x_1, x_2, \dots, x_m$ s.t. $K \subseteq \bigcup_{i=1}^m W_{x_i}$

for each $1 \leq i \leq m$, define

compact set $\rightarrow H_i =$ union of \bar{W}_{x_k} such that $\bar{W}_{x_k} \subseteq V_i$.

Urysohn's lemma $\Rightarrow \exists$ a fn. $\psi_i \in C(X)$ such that
 $H_i \prec \psi_i \prec V_i$. ($0 \leq \psi_i(x) \leq 1$).
($\psi_i \equiv 1$ on H_i & $\psi_i \equiv 0$ on V_i^c).

So to prove this we will use the first theorem that we saw about small existence of small compact above. So from theorem 1 above for each x in the compact set k there exist a neighborhood and open neighborhood let us call it W_x of x such that the closure of W_x lies in some V_i for some i . Now we can take the open cover the unions of these W_x the x in k and this contains k . So by compactness there exist x_1, x_2 finitely many points x_m say such that k is a subset of the finite union $i = 1$ to m W_{x_i} .

And so for each i in 1 to n define H_i to be the union of the compact sets W_{x_i} . Such that these W_x let us write k here W_{x_k} such that W_{x_k} lies in V_i so once you fix i we only choose those W_{x_i} 's whose closure is a subset of V_i so this union is a compact set sitting inside V_i . So now Urysohn's lemma implies that there exist a function C_i continuous function with compact support such that $H_i \prec C_i \prec V_i$.

So this means that C_i is identically 1 on H_i and vanishes outside V_i C_i is identically 1 on H_i and C_i is 0 on V_i complement. And of course we have $0 \leq C_i \leq 1$ for all x so now we will define our Φ_i 's the require our partition of unity using these C_i 's.

(Refer Slide Time: 14:07)

Define

$$Q_1 = \psi_1$$

$$Q_2 = (1 - \psi_1) \cdot \psi_2$$

$$Q_3 = (1 - \psi_1)(1 - \psi_2) \cdot \psi_3$$

⋮

$$Q_n = (1 - \psi_1)(1 - \psi_2) \dots (1 - \psi_{n-1}) \cdot \psi_n$$

Check that:

$$\sum_{i=1}^n Q_i = 1 - (1 - \psi_1)(1 - \psi_2) \dots (1 - \psi_n) \quad [\text{Prove by induction}]$$

$$Q_1 + Q_2 = \psi_1 + (1 - \psi_1)\psi_2 = \psi_1 + \psi_2 - \psi_1\psi_2 + 1 - 1 - \psi_1\psi_2 = 1 - (1 - \psi_1)(1 - \psi_2)$$

So define Phi 1 to be C1 Phi 2 to be 1 – C1 times C2 Phi 3 to be 1 – C1 1 – C2 times C3 and so on. We can define for each i from 1 to n Phi i the last one will be the product 1 – C1, 1 – C2 and so on up to 1 – C n – 1 and multiplied by C n. So now check the following formula that the summation of Phi i, i = 1 to, n is nothing but 1 – C1, 1 – C2 up to 1 – C n. So for example you can prove this by induction. For example if you have just 2 Phi 1 + Phi 2 this is 1 – so first one is C1 + 1 – C1 times C2 and so this is equal to C1 + C2 – C1 C2.

And if you add and subtract 1 so let me add 1 and subtract 1 and we can collect so I will take the positive one and we can collect the other terms as 1 – C1 times 1 – C2. Because this is nothing but 1 – C1 – C2 + C1 C2 and so there is a minus sign here which takes care of the, which gives you the right formula. So we can do it for 2 and then assume for i and rather assume for n – 1 and prove it for n. So I will leave it to you as an exercise to prove this result by induction.

(Refer Slide Time: 17:07)

Since $K \subseteq \bigcup_{i=1}^n H_i$, for each $x \in K$, $x \in H_i$ for some i .

$$\text{and so } \psi_i(x) = 1$$

$$\Rightarrow \left[(1-\psi_1)(1-\psi_2)(1-\psi_3)\dots(1-\psi_n) \right](x) = 0.$$

$$\Rightarrow \sum_{i=1}^n \psi_i(x) = 1 - \underbrace{\prod_{i=1}^n (1-\psi_i(x))}_0 = 1.$$

And now since K is the subset of the union of H_i 's and equal to 1 to, n for each x in K x belongs to H_i for some i and therefore $\psi_i(x)$ equals 1. So this implies that $1 - \psi_1, 1 - \psi_2, 1 - \psi_3$ up to $1 - \psi_n$ applied to x so this function applied at x this is just the point wise multiplication this is 0 for any x . So this implies that the summation of $\psi_i(x)$, $i = 1$ to, n which is $1 -$ this product let me write the product $i = 1$ to n $1 - \psi_i(x)$ this is 0 so this is equal to 1. So these prove the existence of partitions of unity which we will use quite significantly in the proof of the Riesz representation theorem.
