Riesz Representation theorem – Complete statement and proof – Part 2

(Refer Slide Time: 00:17)

Claim: i) $\mu(k) < \infty$ for all k compact
 ii) μ is inner regular on open sets.

(ii) Let U be open in X , let $\alpha < \mu(U)$.
 $\Rightarrow \exists f \ll U$, s.t. $\alpha < \int f < \mu(U)$.

Claim: if $K = \text{supp}(f)$ then $\alpha < \mu(K) < \mu(U) \Rightarrow \mu$ is inner regular for U .

if $g \in C(X)$ such that $K \ll g$, then
 $\int f \leq \int g$. (taking inf over $K \ll g$ on the right).
 since $\alpha < \int f < \mu(U) \Rightarrow \alpha < \mu(K) < \mu(U)$.

So we claim that first is that μk is finite for all k compact this follows immediately because it is the infimum of λf and all these λf 's are finite. So μk is finite. Second is that μ is the inner regular on open sets. So how do we show this? So let u be open in x and suppose that let α be chosen says that it is less than μu . So this implies that there exists f less than u such that $\alpha < \lambda f < \mu u$ because μu is the supremum of all such f 's all such λf .

So if you choose any α less than μu there will be something lying in between μu and α . So now we have choo we have that $\alpha < \lambda f < \mu u$. Now we will show that if k is chosen to be the support of, f which is compact then so let me write it $\alpha < \mu k < \mu u$. So this will show that actually I am proving the second part. So I claim again here that if we choose k to be the compact set support of, f then $\alpha < \mu k < \mu u$ and this implies that μ is inner regular for u right.

So why should this be true if g is a continuous function with compact support such that k is less than g then λf is less than or equal to λg because f is 0 outside of k and g is 1 on k and f takes the maximum value 1. So this means that λf is less than or equal to λg . So since α is less than λf is less than μu this implies that α is less than μk is less than μu by taking infimum over k less than g on the right hand side. So we showed that μ is inner regular on the open set.

(Refer Slide Time: 03:54)

$$(iv) \quad \lambda f = \int_X f d\mu_\lambda \quad \forall f \in C_c(X). \quad (\mu_\lambda = \mu).$$

It suffices to show this for $f \in C_c(X, [0, 1])$.

Since any element of $C_c(X)$ can be expressed as a finite linear combination (with complex coefficients) of elements in $C_c(X, [0, 1])$.

Now we come to the last claim which was the λf is actually given by the integral of f with respect to this $d\mu_\lambda$. So of course, our μ_λ is the μ that we wrote. And to show this we note that it suffices to show this for f in $C_c(X)$ but with range in $[0, 1]$. Because since $C_c(X)$ is a linear span rather any element of $C_c(X)$ can be expressed as a finite linear combination with complex coefficients of elements in $C_c(X, [0, 1])$.

Because f is compactly supported and continuous it has a minimum and a maximum and so we can partition the range into various pieces of size 1. And then we can simply write any element of $C_c(X)$ as a finite linear combination of elements in $C_c(X, [0, 1])$.

(Refer Slide Time: 06:03)

Take $f \in C_c(X, [0,1])$. $K_0 = \text{supp}(f)$

We will define a sequence of compact sets $\{K_j\}_{j=1}^N$ for each $N \in \mathbb{N}$, and also, a seq. of fun. $\{f_j\}_{j=1}^N \in C_c(X, [0,1])$ and such that

$$\frac{1}{N} \mu(K_j) \leq \int_X f_j d\mu \leq \frac{1}{N} \mu(K_{j-1}), \quad j \in \{1, \dots, N\}$$

and similarly, $\frac{1}{N} \mu(K_j) \leq \lambda(f_j) \leq \frac{1}{N} \mu(K_{j-1})$

$\{f_j\}_{j=1}^N$ will satisfy $(f = \sum_{j=1}^N f_j) \Rightarrow$

$$\frac{1}{N} \sum_{j=1}^N \mu(K_j) \leq \int_X f d\mu \leq \frac{1}{N} \sum_{j=0}^{N-1} \mu(K_j).$$

So let us take a function take a function f which is continuous compactly supported with values in the interval $0, 1$. So we denote k_0 to the support of, f which is compact. Now we will define a sequence of a compact sets $k_j, j = 1$ to N for each N in \mathbb{N} and we will define and also a sequence of functions f_j which will be again in $c_0 \times 0, 1$. So this is again a sequence $j = 1$ to N and such that we will have $\frac{1}{N} \sum_{j=1}^N \mu$ of k_j less than or equal to $\int f_j d\mu$ over x which is less than or equal to $\frac{1}{N} \sum_{j=0}^{N-1} \mu$ of k_{j-1} .

And similarly we will have the same inequality for λ of, $f_j \mu k_j$ less than or equal to λ of, f_j and this is less than or equal to $\sum_{j=0}^{N-1} \mu$ of k_{j-1} . And this sequence of function $f_j, j = 1$ to N will satisfy there is no summation here yet. These are inequalities that we have and this f_j will satisfy that f the function f that we started out with is the sum of all these f_j . And so this would imply that $\frac{1}{N}$ if you sum this inequality so this is for each j for each j in 1 up to n .

So if you sum all these inequalities all these are non-negative numbers. So you can sum all these inequalities and you will get on the left hand side some of $\mu k_j, j = 1$ to N and in the middle you will get for the first one $f d\mu$ because f is the sum of, f_j 's. On the right hand side you will get $\sum_{j=0}^{N-1} \mu$ of k_j .

(Refer Slide Time: 09:55)

Similarly,

$$\frac{1}{N} \sum_{j=1}^N \mu(k_j) \leq \Lambda(f) \leq \frac{1}{N} \sum_{j=0}^{N-1} \mu(k_j) -$$

$$\Rightarrow \left| \Lambda(f) - \int_X f d\mu \right| \leq \frac{1}{N} (\mu(k_0) - \mu(k_N)) = \frac{1}{N} \mu(k_0 \setminus k_N)$$

$$\leq \frac{1}{N} \underbrace{\mu(k_0)}_{< \infty} \rightarrow 0 \text{ as } N \rightarrow \infty.$$

Let $K_j = \{x \in X : f(x) \geq \frac{j}{N}\}$ for each $j \in \{1, \dots, N\}$.

$$f_j = \min \left\{ \max \left\{ f - \frac{j-1}{N}, 0 \right\}, \frac{1}{N} \right\}$$

So: Check that $f = \sum_{j=1}^N f_j$

And similarly we also have the same inequality lambda of, f. So you will have mu k j, j = 1 to N on the left lambda f and then on the right you have the sum j = to 0 to N - 1 mu k j. So this implies that the difference lambda f - f d mu has absolute value less than or equal to 1 over N mu of k 0 - mu of k N from just by subtracting this inequality with the one for integral f d mu. So since this, is equal to 1 over N mu of k 0 - k N and this is less than or equal to 1 over N mu of support of, f which is k 0.

So this part is finite and N is arbitrary so this goes to 0 as N goes to infinity which implies that these two things are equal. So now we have to just build up our sequence of compact sets k j and our sequence of function f j such that they satisfy these inequalities, as well as that f is the sum over all these f j's f is the sum over all these f j's. So we will use the following formula so let k j be the set of points in x such that f x is greater than or equal to j over N for each j between 1 to N.

And f j is equal to the minimum of the maximum of f - j - 1 over N comma 0 you take the maximum of these 2 things and the minimum of this value and 1 over n. So one has to check that so this is an exercise check that f = sum over f j, j = 1 to N. So let us see what these f j look like.

(Refer Slide Time: 12:52)

So let suppose that x is our real line and we have nice function bell shaped function with the compact support given by the interval a , to b and the height is exactly equal to 1. So let see what we have done first of all we have divided this range into parts of length 1 over N . So this is 1 over N and so we have divided the whole thing like this so each has width or height 1 over N . So now let us see what is our f_1 so $j = 1$ for $j = 1$ f_1 is the minimum of the maximum of $f - j - 1$ over n .

So it is 0 comma 1 over N . So this is nothing but the minimum of, f comma 1 over N . So now let see what is K_1 this is equal to the set of all point such that $f x$ is greater than or equal to 1 over n which means that K_1 is nothing but this set her. So if you take this point and if you take this point then I will denote that N point as a_1 and b_1 and in within this interval a_1 and b_1 the value of $f x$ is greater than or equal to this value 1 over N .

So $f x$ has values upwards of 1 over n so this is our K_1 . So now let us see what kind of graph f_1 has so f_1 is equal to f_1 of x . So now we can have the partition if a_0 sorry if a less than or equal to x less than or equal to or less than a_1 . Then we have that f_1 is less than 1 over N . So f_1 is simply f so this is $f x$. Now if a_1 less than or equal to x less than or equal to b_1 then it will have so in this region it is having this part in the graph.

But in the interval a_1 to b_1 it is going to be constant because we are taking the minimum of f and $1 / N$, $n y 1 / N$ and on K_1 the value of f is greater than $1 / N$. So within in K_1 it is going to be

constant it takes the constant value 1 over N and then again so let me write it here is 1 over N. And again if b_1 less than x less than or equal to b then again it is f of x so this part of the graph is also part of f_1 . So this is f_1 .

(Refer Slide Time: 17:11)

Now let us look at what kind of graph f_2 has it will be having a similar kind of graph. So now let us take $j = 2$ and now we have f_2 is the minimum now the maximum value of $f - 1/N$ comma 0 and the minimum value of this value and $1/N$. And we have k_2 is the set of all points such that f x is greater than or equal to $2/N$. So let us see what kind of set we get for k_2 . So this height is $2/N$ and so for k_2 we will get this interval a_2 b_2 and this is k_2 .

And now f_2 if we take f_2 x then between 0 less than or equal to x less than or equal to a_1 what do we get? So it is the maximum value of $f - 1/N$ comma 0. But $f - 1/N$ is negative in this region because f is less than or equal to $1/N$. And so this is going to be simply 0 and we take the minimum of 0 $1/N$ so this is again 0. So this is between a , and a_1 . Let us take between a_1 and a_2 . Between a_1 and a_2 the function has a value greater than $1/N$ but less than $2/N$.

So if you take the maximum of $f - 1/N$ comma 0 you will get $f - 1/N$. And $f - 1/N$ is still greater than $1/N$ because it is less than or equal to $2/N$. So you will get $f - f(x) - 1/N$. So you are taking this part so let me take another color. So you are taking this part and you are pushing it down $1/N$. So this part is 0 this part is just the copy of the one in green part above. And then we will have again $1/N$ in this part for k_2 .

So for a_2 less than or equal to x less than or equal to b_2 it will have simply $1/N$. And then again if b_1 less than x less than b_2 less than x less than b_1 you will get $f(x) = 1/N$. And if b_1 less than or equal to x less than b we will get $f(x)$ to be simply 0. So here in magenta color we will have up to here $1/N$. So this is $1/N$. And then again this part is dropped up to here and then you will get a 0. So this is the graph for f_2 . So in fact one can write down a general formula for f_j .

(Refer Slide Time: 21:01)

Since $\mu(k) = \inf \{ \lambda f : k \leq f \}$ - property (v)

$\frac{1}{N} \mu(k_j) \leq f_j \Rightarrow k_j \leq f_j$

$\Rightarrow \frac{1}{N} \mu(k_j) \leq \lambda(f_j) \leq \frac{1}{N} \mu(u)$

for any open $u \geq k_{j-1}$

since $f_j = 0$ outside $k_{j-1} \Rightarrow k_j < f_j < u$

for any open u containing k_{j-1}

By outer regularity;

$\frac{1}{N} \mu(k_j) \leq \lambda(f_j) \leq \frac{1}{N} \mu(k_{j-1})$

So $f_j(x)$ for j in $1, 2, \dots, N$ we have $f_j(x)$ is equal to this is equal to 0 if x does not belong to k_{j-1} this is going to be 0. If x belongs to $k_{j-1} - k_j$ notices that k_j is the subset of k_{j-1} for h_j . And for this case we will have $f_j(x) = \frac{1}{N}$ and finally if x belongs to k_j then it is going to be $\frac{1}{N}$. So this implies that we have the point wise inequality $\frac{1}{N} \chi_{k_j} \leq f_j \leq \frac{1}{N} \chi_{k_{j-1}}$.

And we also have that f is equal summation of $f_j, j = 1$ to N . And if we integrate this inequality we get $\frac{1}{N} \mu(k_j) \leq \int f_j d\mu \leq \frac{1}{N} \mu(k_{j-1})$. And now we are going to use the fact that μ is radon to derive a similar formula for λf_j . So since $\mu(k_j)$ is the infimum of all the λf such that $k_j \leq f$. This implies that $\frac{1}{N} \mu(k_j) \leq \lambda f_j$ this is because $\frac{1}{N} \chi_{k_j} \leq f_j$.

So this means that $\int_{K_j} f d\mu$ is less than $\int_{K_j} f d\lambda$. So this implies $\frac{1}{N} \int_{K_j} f d\mu$ is less than or equal to $\frac{1}{N} \int_{K_j} f d\lambda$. And on the other hand we have that $\frac{1}{N} \int_{K_j} f d\lambda$ is less than or equal to $\frac{1}{N} \int_{U} f d\mu$ for any open U containing K_j . This is because simply because $f \geq 0$ since f is equal to 0 outside K_j . So this implies that $\int_{K_j} f d\mu \leq \int_{U} f d\mu$ for any open U containing K_j . Now by outer regularity so this was property 2 that we proved before property 2.

And now by outer regularity we can approximate $\mu(K_j)$ with respect to the open set and so we can take the infimum on the right hand side. So we get $\frac{1}{N} \int_{K_j} f d\mu \leq \frac{1}{N} \int_{U} f d\mu$ is less than or equal to $\frac{1}{N} \int_{K_j} f d\lambda$ and this is what we wanted to show in order to derive our result. So let us go back to these 2 results so one was this when you sum up all the inequalities.

So this is this was the first inequality that we needed $\frac{1}{N} \int_{K_j} f d\mu \leq \frac{1}{N} \int_{K_j} f d\lambda$. And similarly the same inequality for λ in N place of the Lebesgue integral. And now you sum it up and then you derive that $\lambda(U) - \int_U f d\mu$ is less than or equal to $\frac{1}{N} \int_{K_j} f d\mu$ which goes to 0 as N goes to infinity. So this finishes the proof of the fourth part which said that $\lambda(U) = \int_U f d\mu$. Now we have to show one more thing which is uniqueness.

(Refer Slide Time: 26:34)

Uniqueness: If μ' is another Radon measure on X such that $\int f d\mu' = \int f d\lambda$ for all $f \in C_c(X)$.

To show: $\mu' = \mu$
it suffices to show that $\mu'(U) = \sup \{ \int f d\mu' : f \geq 0, \text{supp}(f) \subset U \}$ (for U open).

if U is open, and $K \subset U$, K compact.
By Urysohn's lemma, $\exists f \in C_c(X, [0,1])$ s.t. $1 \leq f \leq \chi_U$.

$\Rightarrow \chi_K \leq f \leq \chi_U$.

$\Rightarrow \int \chi_K d\mu' \leq \int f d\mu' = \int f d\lambda \leq \int \chi_U d\mu = \mu(U)$

Since μ' is inner regular on open sets $\Rightarrow \mu'(U) = \sup \{ \int f d\mu' : f \geq 0, \text{supp}(f) \subset U \}$

So suppose that μ' is another Radon measure on X such that $\int f d\mu' = \int f d\lambda$ for all $f \in C_c(X)$. But then we have so it suffices to show that μ' equals to

μ it suffices to show that $\mu \llcorner u$ is given by the same formula of the supremum of λf such that f is less than u and this was by definition our μ of u . So then we just have to show this result and to show this result we proceed as follows.

So if u is open so this is for u open. If u is open and k a subset of u a compact subset and I am going to use the inner regularity of $\mu \llcorner$ because it is a Radon measure in regularity for open sets. So, now by Urysohn's lemma there exists f in $C(X, [0, 1])$ such that $k \llcorner f \llcorner u$. And this implies that because λf is given by the integral this implies that $\mu \llcorner k$ if you integrate the indicative functions.

So let me write it in terms of indicative function so χ_k is less than or equal to f less than or equal to χ_u . And now if you integrate you get $\mu \llcorner k$ less than or equal to $\int f d\mu \llcorner$ which is equal to λf and this is less than or equal to $\mu \llcorner u$. And now since $\mu \llcorner$ is inner regular on open sets this implies that $\mu \llcorner u$ is the supremum of all such λf such that f is less than u .

Because the left hand side converges to $\mu \llcorner u$ as you take an increasing sequence of compact subsets of u . So we also prove we have also proven uniqueness and this finishes the proof of the Riesz representation theorem. And now in the next lecture we will see what kind of examples of measure we can construct out of the Riesz representation theorem.
