Examples of measures constructed using RRT

(Refer Slide Time: 00:20)

Now we take a look at the examples of measures constructed out of the Riesz representation theorem. So our first example should of course be whether it should answer whether the Lebesgue measure can be constructed out of the Riesz representation theorem. And of course the answer is yes as I mentioned before that the Lebesgue measure can be constructed using the Riemann integral functional.

Secondly we have seen the Dirac measure this can also be constructed using the Riesz representation theorem. And lastly I will just give an example what are called Haar measures so these are measures on locally compact Hausdorff topological groups. So these are groups which have an underlined space with the topology so the underlying space of the group is the topological space and it is locally compact Hausdorff.

A topological group in a topological group the group operations are continuous with respect to the topology. So a group multiplication and inverse operations are continuous with respect to the

group topology and we will construct a not for general groups but only for $G = \mathbb{R}$ star which the group of the multiplicative group of non-zero real's. So with the multiplication operation so let us look at how to construct the Lebesgue measure from the Riesz representation theorem.

(Refer Slide Time: 02:39)

1) Lebesgue measure: $X = \mathbb{R}^d$, we take the positive linear functional

$$\Lambda_{\mathbb{R}} : C_c(\mathbb{R}^d) \rightarrow \mathbb{C}$$

$$\Lambda_{\mathbb{R}}(f) := \int_{\mathbb{R}^d} f(x) dx \leftarrow \text{Riemann integral of } f$$

$$= \int f(x) dx.$$

(Bump)

Check: $\Lambda_{\mathbb{R}}$ is a positive linear functional on $C_c(X)$.

\leadsto induces a Radon measure $\mu_{\mathbb{R}}$ on \mathbb{R}^d .

Claim: $\mu_{\mathbb{R}} = m$ (Lebesgue measure).

So first is the Lebesgue measure so we have X is \mathbb{R}^d and we take the positive linear functional actually positive linear functional which I will denote by $\lambda_{\mathbb{R}}$ which is from $C_c(\mathbb{R}^d)$ to \mathbb{C} . And this $\lambda_{\mathbb{R}}$ is given by is the Riemann integral this is the Riemann integral of, f . So notice that since f has compact support and it is continuous f is Riemann integrable. And you can in fact replace \mathbb{R}^d here by some large box that contains the support of f , $\int f(x) dx$.

So of course this $\lambda_{\mathbb{R}}$ is a positive linear functional as claimed so one can check that $\lambda_{\mathbb{R}}$ is a positive linear function on $C_c(X)$. So by the Riesz representation theorem it induces a Radon measure $\mu_{\mathbb{R}}$ on \mathbb{R}^d . And so the claim is that $\mu_{\mathbb{R}}$ is nothing but our Lebesgue measure on \mathbb{R}^d . So to show this it is enough to show that $\mu_{\mathbb{R}}$ and m agree on open sets because remember that the outer measure that was defined in the Riesz representation theorem was defined using measures of open sets approximated from above.

And so if we have this equality on open sets it is enough to show that $\mu_{\mathbb{R}} = m$ because then the outer measures will be the same, and then the sigma algebra generated by the Caratheodory measurable sets will be same and so the measures will also be the same.

(Refer Slide Time: 05:54)

Ex. i) Any Riemann integrable fn. $f: \mathbb{R}^d \rightarrow \mathbb{C}$ is Lebesgue integrable and

$$\text{Riemann} \rightarrow \int_{\mathbb{R}^d} f(x) dx = \int_{\mathbb{R}^d} f d\mu. \leftarrow \text{Lebesgue.}$$

$$ii) m^*(E) = \inf \left\{ \sum_{j=1}^{\infty} m^*(U_j) : E \subseteq \bigcup_{j=1}^{\infty} U_j, U_j \text{ open} \right\}$$

(Use that U open is a countable union of almost-disjoint closed boxes).

It suffices to show that $\mu_{\mathbb{R}^d}(U) = m(U)$ for U open in \mathbb{R}^d .

Suppose that $\mu_{\mathbb{R}^d}(U) < \infty$

So we need a few results that I will leave as an exercise so the first is that any Riemann integrable function f on \mathbb{R}^d is Lebesgue integrable. And in this case we have that the Riemann integral of $f x dx$ of, f is equal to the Lebesgue integral of, f with respect to the Lebesgue measure. So, on the left hand side we have the Riemann integral and on the right hand side we have the Lebesgue integral.

So the Lebesgue measure can be seen as a generalization of the Riemann integral and if, f is the Riemann integrable then it is Lebesgue integrable and the 2 concepts agree for Riemann integrable functions. So that is the first one second one second point is that m^* of E the Lebesgue outer measure can be written as the infimum of sums of m^* of U_j , $j = 1$ to infinity such that E is the subset of the union of U_j 's and each of the U_j 's are open.

So for example you can use that U open is a countable union of boxes of almost disjoint close boxes union of almost disjoint close boxes. So once we have this we have already seen that the outer measure defined in the Riesz representation theorem was defined using the μ 's that were defined on open sets using the functional and then we define the outer measure like this. So if the measure from the Riesz representation theorem agrees with the Lebesgue measure for open sets then the outer measures will also agree.

And then the sigma algebra generated of by the Caratheodory measureable sets will also agree and the measures will also agree. So it suffices to show that $\mu_R u$ equals μu for u open in \mathbb{R}^d . So first suppose that $\mu_R u$ is finite.

(Refer Slide Time: 09:27)

So let $\epsilon > 0$, and choose $f < u$ st.

$$\begin{aligned} \mu_R(u) &\leq \lambda_R(f) + \epsilon \\ &= \int_{\mathbb{R}^d} f(x) dx + \epsilon \\ &= \int_{\mathbb{R}^d} f dm + \epsilon \\ &\leq \int_{\mathbb{R}^d} \chi_u dm + \epsilon \quad (\text{since } f \leq \chi_u) \\ &= m(u) + \epsilon \Rightarrow \mu_R(u) \leq m(u). \end{aligned}$$

So let epsilon be greater than 0 and choose f less than u such that $\mu_R u$ is less than or equal to $\lambda_R f + \epsilon$. So this is because the μ_R is the supremum of all such $\lambda_R f$ so you can choose one such which is close to $\mu_R u$. And this is nothing but the integral by definition of $\lambda_R f$ this is the Riemann integral of, f . And now we know that this is also the Lebesgue integral of, f .

And this is nothing well this is less than or equal to the integral of $\chi_u dm + \epsilon$ since f is less than or equal to χ_u . And the last is nothing but $\mu u + \epsilon$ so this means that $\mu_R u$ is less than or equal to μu .

(Refer Slide Time: 10:49)

Let $U_n = U \cap B(0, n) \Rightarrow m(U_n) < \infty$
 and $U = \bigcup_{n=1}^{\infty} U_n$

For each $n \geq 1$, since $m(U_n)$ is finite, by the density of $C_c(\mathbb{R}^d)$ in L^1 ,
 we can choose a function $f_n \in C_c(\mathbb{R}^d, [0, 1])$ s.t. $0 \leq f_n \leq \chi_{U_n} \leq \chi_U$.
 and $\|\chi_{U_n} - f_n\|_{L^1} \leq \epsilon$. $\Rightarrow f_n \leq \chi_U$

$\Rightarrow \int (\chi_{U_n} - f_n) dm \leq \epsilon$

$\Rightarrow \int_{\mathbb{R}^d} \chi_{U_n} dm \leq \int_{\mathbb{R}^d} f_n dm + \epsilon = \int_{\mathbb{R}^d} f_n dx + \epsilon$ (Riemann)
 $= \mu_R(f_n) + \epsilon \leq \mu_R(U) + \epsilon$

$\Rightarrow m(U) \leq \mu_R(U) + \epsilon$ (By UMCCT) $\Rightarrow m(U) \leq \mu_R(U)$

Now for the reverse inclusion let U_n be the intersection of U with the open ball of radius n and center 0 . So that the measure of U_n is finite and U is the union of these is U_n 's $n = 1$ to infinity and now for each n . Since the measure is finite by the density of $C_c(\mathbb{R}^d)$ in L^1 we can choose a function f_n in $C_c(\mathbb{R}^d)$ with values in $[0, 1]$. Such that $0 \leq f_n \leq \chi_{U_n}$ and the L^1 norm of $\chi_{U_n} - f_n$ is less or equal to ϵ .

But what does this mean? This means that the integral $\int (\chi_{U_n} - f_n) dm$ is less than or equal to ϵ . And now both are finite so this is $m(U_n) - \int_{\mathbb{R}^d} f_n dm$ which is less than or equal to ϵ . So you can take it on the other side and you will have less than $m(U_n)$ is less than or equal to this integral plus ϵ . And now we have seen that Lebesgue integral and Riemann integral coincide for continuous compactly supported functions.

So this is equal to $\int_{\mathbb{R}^d} f_n dx + \epsilon$ where this is now the Riemann integral of f_n plus ϵ and on the left hand side you have $m(U_n) - \int_{\mathbb{R}^d} f_n dx + \epsilon$. And now note that since f_n is less than or equal to χ_{U_n} and χ_{U_n} is less or equal to χ_U this means that f_n is less than U . So f_n has compact support inside U and so this is less than or equal to $\mu_R(U) + \epsilon$.

And now we can take the limit on the left hand side to get $m(U) \leq \mu_R(U) + \epsilon$ by upward monotone convergence theorem for the Lebesgue measure. So this implies that $m(U)$ is less or equal to $\mu_R(U)$ and we are done. So we have shown that for open sets so we

assume that this was finite and leave it to you as an exercise to show this for the case when this is infinite but then again you can use a limiting argument as I have done here.

So I will leave it to you as an exercise so this shows that the Lebesgue measure can be constructed out of the Riemann integral functional in this way we can see the Lebesgue integration as a completion of Riemann integration.

(Refer Slide Time: 14:51)

(2) Dirac measure on X: if $x_0 \in X$

$$\mu_{x_0}(E) = \begin{cases} 1 & \text{if } x_0 \in E \\ 0 & \text{otherwise.} \end{cases}$$

Consider the evaluation functional:

$$ev_{x_0}: C(X) \rightarrow [0, 1]$$

$$ev_{x_0}(f) := f(x_0) \quad [\text{this is a +ve linear functional}]$$

Ex: Check that the induced measure from ev_{x_0} is μ_{x_0} .

Remark: Note that if $\{x_i\}_{i=1}^N$ is a collection of points of X and $\alpha_1, \alpha_2, \dots, \alpha_N$ are +ve real numbers, then

$$ev(\alpha_1, \alpha_2) := \sum_{i=1}^N \alpha_i ev_{x_i} \quad (\text{also a +ve linear fun.})$$

Another example is the construction on the Dirac measure on X we have already seen what it is? So if we fix a point x_0 in X then μ_{x_0} of a set E is equal to 1 if x_0 belongs to E and 0 otherwise. So I will construct measure out of the Riesz representation theorem by considering the evaluation functional which is given by. So I will write $E \subset X$ from X to 0, 1 and this is by definition sorry this is over $C(X)$ to 0, 1.

And if you apply a function with continuous function with compact support then by definition this is $f(x_0)$ this is why it is called evaluation because it is evaluating the function f at the point x_0 . And as an exercise I will leave it you to check that the induced measure from the evaluation functional. So the first one has to check that this is a positive linear functional this is quite straight forward because if f is positive then $f(x_0)$ is positive and linearity is obvious because $f + g$ is defined using the point wise addition so it is positive so it is also linear.

And now we have to check that the induced measure from ν is indeed the Dirac measure μ_X . So I leave it to you as an exercise and as a remark note that if $x_i, i = 1$ to N is a collection of points of X and $\alpha_1, \alpha_2, \dots, \alpha_n$ are positive real numbers. Then the finite linear combination $\sum_{i=1}^n \alpha_i \nu(x_i)$ so let me denote $\nu(x_i)$ this is the finite linear combination of the evaluation functional with coefficient α_i .

(Refer Slide Time: 18:17)

$$\Rightarrow \mu_{(\alpha_i, x_i)}(E) = \begin{cases} \sum_{k=1}^m \alpha_k & \text{if } x_1, x_2, \dots, x_m \in E \\ 0 & \text{otherwise.} \end{cases}$$

3) Haar measure on a topological (LCH) group:

Def: Let G be a LCH top group. Then a ^{left} Haar measure on G is a Radon measure μ on G s.t.

$$\mu(gE) = \mu(E) \quad \text{for any Borel set } E \subseteq G.$$

$$gE := \{g \cdot e : e \in E\} \quad \leftarrow \text{left-translation invariance.}$$

$\mathbb{R}^n: i) (\mathbb{R}^n, +), m \rightarrow$ Haar measure. (since m is translation-invariant)

This is also a positive linear functional so the induced measure over these points $i = 1$ to, n is given by the following formula is equal to sum of α_i . If so it is sum of α_i $k = 1$ to m if x_1, x_2 up to x_m belong to E and 0 otherwise. So the maximal set of points that belong to E that contribute to this measure but it will be 0 otherwise. So it is generalization of the Dirac measure and you can construct this using the Riesz representation theorem.

Now the third example is the Haar measure on topological group well we also wanted to be LCH locally compact Hausdorff. So a Haar measure so let G be a locally compact Hausdorff topological group. Then a Haar measure on G is a Radon measure on G such that so Radon measure so let me denote it by μ such that the measure of gE is equal to measure of E where $g \in G$. So this is for any Borel set E inside G and gE by definition the set of points $g \cdot e$ such that $e \in E$.

So here we are just using the group operation so this is called the left translation invariance property invariance. And in fact this is what is called a left Haar measure so you can also have

the right Haar measure where g acts on the right and you could also ask for both but it is rare. So as an example we have \mathbb{R}^d where \mathbb{R}^d is taken as the topological group with the addition with the Lebesgue measure m this is a Haar measure.

Because m is translation invariant so this group is a (\mathbb{R}^d) (21:54) groups so left and right actions are both the same. So this give you a Haar measure so that is one example.

(Refer Slide Time: 22:04)

ii) $G = \mathbb{R}^* = (\mathbb{R} \setminus \{0\}, \times)$

Define for $f \in C_c(G)$:

$$\lambda(f) := \int_{\mathbb{R} \setminus \{0\}} f(x) \frac{dx}{|x|}$$

λ is a positive linear functional, which gives the measure (in \mathbb{R}^d)

$\mathbb{R}^* \ni A$ Borel ; $m_\lambda^*(A) = \int_A \frac{dx}{|x|}$

$0 < a < b$; $m_\lambda^*([a,b]) = \int_a^b \frac{dx}{|x|} = \int_a^b \frac{dx}{x} = \ln\left(\frac{b}{a}\right)$

$c > 0$; $m_\lambda^*(c \cdot [a,b]) = m_\lambda^*([ca, cb]) = \ln\left(\frac{cb}{ca}\right) = \ln\left(\frac{b}{a}\right) = m_\lambda^*([a,b])$

Another example is of G is the multiplicative group of real's so this is $\mathbb{R} - 0$ with the multiplication operation. And if you define for f in $C_c(G)$ $\lambda(f)$ as the integral of, f over $\mathbb{R}^* \int f(x) dx$ over mod x . So this is over set $\mathbb{R} - 0$ and this is the usual we can take it as the Lebesgue integral and if you define this functional in this way then it is again is a positive linear functional which gives the measure via the Riesz representation theorem given by.

So let me denote m_λ as a measure induced by λ so m_λ of A where A is a Borel subset of \mathbb{R}^* is given by the integral over A of dx over mod x . So for example m_λ of an interval a, b . So $a - 0$ so of course is a subset of \mathbb{R}^* so a will not contain 0 anyway so $a, b - 0$ if a is if this interval contains 0 then we remove it from it from this interval. And so this will be the integral well let me take it both positive so that it is easier.

So then there is no zero inside and so this is simply the integral from a to b of dx over mod x which is the same as integral over a to b of dx over x and this is $\ln(b/a)$. And it is a left invariant

because $m \star \lambda$ of c times this interval a, b for example this is nothing but the measure of the interval $c a, c b$ and this is nothing but \ln of $c b / c a$. Here again I am taking C to be positive strictly positive so then you will have you can also take it to this strictly negative but then you will have $\ln c b$ over $c a$.

So this is again $\ln b$ over a with is $m \star \lambda$ a, b so this is with respect to the multiplication group operation this is invariant. So this is the Haar measure on the group of multiplicative non-negative real's
