Def: A Galois extension is normal, but the converse is not true.  
 In char 0, Galois  $\Leftrightarrow$  normal (for finite extensions)

Problems: Find the Galois groups and determine if the extensions are Galois or normal.

(1)  $K = \mathbb{Q}(\sqrt[3]{2})$ ,  $F = \mathbb{Q}$   
 Galois group =  $\{1\}$ ; not Galois, not normal  
 $[K:\mathbb{Q}] = 3$ , but  $|\text{Gal}(K/\mathbb{Q})| = 1$   
 $x^3 - 2 \in \mathbb{Q}[x]$  is irr, has a root in  $K$ , but doesn't split completely

(2)  $K = \mathbb{Q}(\sqrt{2}, i)$ ,  $F = \mathbb{Q}$   
 Galois group =  $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$   
 4 elements in  $\text{Gal}(K/F)$ ,  $|\text{Gal}(K/F)| = 4$

Okay, let us continue. In the last video we started doing some problems. So, let me do one more example. So, the problem asked us to find the Galois groups and determine if the extensions are Galois or normal. So, we did a few, let me do one more. And this is also an example that we discussed earlier, but I want to finish the example by proving various statements that I was making in the past.

(Refer Slide Time: 02:55)

6)  $K = \mathbb{F}_{p^r}$  Recall: Frobenius homom:  $\sigma: K \rightarrow K$   
 $\sigma(x) = x^p$   
 $\mathbb{F} = \mathbb{F}_p$  (F-sub of  $K$ )  
 checked:  $\sigma$  is a field homom,  $\sigma$  injective }  $\sigma$  is an  
 $\sigma$  is surjective,  $\sigma(a) = a \forall a \in \mathbb{F}_p$  } F-auto of  $K$

So  $\sigma \in \text{Gal}(K/\mathbb{F})$ .

Claim: order of  $\sigma$  in  $\text{Gal}(K/\mathbb{F})$  is  $r$ .

$\mathbb{F} = \mathbb{F}_p$  checked:  $\sigma$  is a field homom,  $\sigma$  injective }  $\sigma$  is an  
 $\sigma$  is surjective,  $\sigma(a) = a \forall a \in \mathbb{F}_p$  } F-auto of  $K$

So  $\sigma \in \text{Gal}(K/\mathbb{F})$ .

Claim: order of  $\sigma$  in  $\text{Gal}(K/\mathbb{F})$  is  $r$ .

$\sigma^2(\alpha) = \sigma(\sigma(\alpha)) = \sigma(\alpha^p) = (\alpha^p)^p = \alpha^{p^2}$ . Similarly  
 $\sigma^i(\alpha) = \alpha^{p^i} \forall \alpha \forall i \geq 1$ .

Suppose order of  $\sigma = n \Rightarrow \sigma^n = 1$ .

$\therefore \sigma^n(\alpha) = \alpha \forall \alpha \in K \Rightarrow \alpha^{p^n} = \alpha \forall \alpha \in K$   
 $\Rightarrow \alpha$  is a root of  $X^{p^n} - X$  in  $K$ .  
 $\forall \alpha \in K$

Since  $\deg(X^{p^n} - X) = p^n$ ,  $X^{p^n} - X$  has at most  $p^n$  roots in  $K$ .

General statement:  
 $f \in F[X]$  deg  $f = n$   
 has at most  $n$  roots  
 in  $F$  (must be a  
 field)

But every elt of  $K$  is a root of  $X^{p^n} - X$

So  $|K| = p^r \leq p^n \Rightarrow r \leq n$ .

But  $\sigma^{-r}(\alpha) = \alpha^{p^r} = \alpha$  ( $\because$  elts of  $K$  are roots of)

Let  $f \in F[X]$ ,  $\deg f = n$   
 has at most  $n$  roots  
 in  $F$ . Finite field

Let  $K$  be any subfield

So  $|K| = p^r \leq p^n \Rightarrow r \leq n$ .  
 But  $\sigma^r(\alpha) = \alpha^p = \alpha$  ( $\because$  elts of  $K$  are roots of  $x^{p^r} - x$ )  
 $\Rightarrow \sigma^r = 1$   
 $\Rightarrow \text{ord}(\sigma) \leq r$  Hence  $n=r$   $\square$

$\therefore$  The subgp gen by  $\sigma$  in  $\text{Gal}(F_p^r/F_p)$  has order  $r$ .  
 $\{1, \sigma, \sigma^2, \dots, \sigma^{r-1}\}$

in  $F$  Finite field

But  $\sigma^r(\alpha) = \alpha^p = \alpha$  ( $\because$  elts of  $K$  are roots of  $x^{p^r} - x$ )  
 $\Rightarrow \sigma^r = 1$   
 $\Rightarrow \text{ord}(\sigma) \leq r$  Hence  $n=r$   $\square$

$$\begin{array}{c} F_p^r \\ | \\ F_p^G \\ | \\ F_p \end{array}$$

$\therefore$  The subgp gen by  $\sigma$  in  $\text{Gal}(F_p^r/F_p)$  has order  $r$ .  
 $\{1, \sigma, \sigma^2, \dots, \sigma^{r-1}\}$  Hence  $|G| \geq r$ .

$$r = [F_p^r : F_p] \geq [F_p^r : F_p^G] = |G| \geq r$$

$$\Rightarrow [F_p^r : F_p^G] = r \Rightarrow [F_p^G : F_p] = 1$$

$$\begin{array}{c} F_p^r \\ | \\ F_p^G \\ | \\ F_p \end{array}$$

$\therefore$  The subgp gen by  $\sigma$  in  $\text{Gal}(F_p^r/F_p)$  has order  $r$ .  
 $\{1, \sigma, \sigma^2, \dots, \sigma^{r-1}\}$  Hence  $|G| \geq r$ .

$$r = [F_p^r : F_p] \geq [F_p^r : F_p^G] = |G| \geq r$$

$$\Rightarrow [F_p^r : F_p^G] = r \Rightarrow [F_p^G : F_p] = 1 \Rightarrow F_p^G = F_p$$

Hence  $F_p^r/F_p$  is Galois and  $\text{Gal}(F_p^r/F_p) \cong \mathbb{Z}/r\mathbb{Z}$   $\square$

So, the first field is  $\mathbb{F}_P$  and this is  $\mathbb{F}$ , so this is  $\mathbb{F}$ . So of course, as usual, in this case,  $P$  is a prime number,  $R$  is a positive integer and  $\mathbb{F}_P$  is the field of order  $P$  power  $R$ .  $\mathbb{F}$  is a field of order  $P$ , and this degree  $R$  extension. So in this case, let us compute the Galois group. And let us see if it is Galois and if it is normal. So, in this case, potentially Galois and normal could be different, because this is not characteristic zero.

So, and we recalled earlier the Frobenius map that we defined, Frobenius homomorphism. So, this is, in fact, a  $\mathbb{F}$  homomorphism of  $\mathbb{F}$  automorphism in fact, of  $K$ , namely this is  $K$  to  $K$ , sends  $\alpha$  to  $\alpha^P$ . For every  $\alpha$  you send it to its  $P$ th power. What we have checked is, checked or earlier or at least remarked earlier that  $\sigma$  is a field homomorphism.

This is because of the characteristic  $P$ , only real thing to check is  $\alpha + \beta$  goes to  $\alpha^P + \beta^P$ , which it does because of characteristic  $P$ ,  $\sigma$  is of course, injective being a field homomorphism. So,  $\sigma$  is surjective also, because it is an injective map from a finite set to itself. So, it must be surjective. So, it is an automorphism. And  $\sigma(A) = A$  for all  $A$  in  $\mathbb{F}_P$ , because every element of  $\mathbb{F}_P$  has  $P$ th power equal to itself.

So, this is the proof that  $\sigma$  is an  $\mathbb{F}$  automorphism of  $K$ . So far so good, that means, in the new language of Galois groups, what we can say is that  $\sigma$  belongs to the Galois group of  $K$  over  $\mathbb{F}$ . So, it is  $\mathbb{F}$  automorphism of  $K$ . Now, let us see what the Galois group is, so it contains  $\sigma$ , but let us see what more can it contain. So, I first claim that order of  $\sigma$  in the Galois group as an element of the Galois group is  $r$ .

So, order means it is the least integers such that  $\sigma^R$  is identity, least positive integer. First we note a few things, for example, what is  $\sigma^2$  of  $\alpha$ ;  $\sigma^2$  of  $\alpha$  is  $\sigma(\sigma(\alpha))$ , which is  $\sigma(\alpha^P)$ , which is  $\alpha^{P^2}$ . What is  $\sigma$  of  $\alpha^{P^2}$ ? It is  $\alpha^{P^3}$ , so this is  $\alpha^{P^2}$ .

So, similarly you can check, so similarly, this is, I mean I did one case, but similarly is we can check that  $\sigma^i$  of  $\alpha$  is  $\alpha^{P^i}$ , for all  $\alpha$  and for all  $i$ . Now, suppose order of  $\sigma$  is  $n$ , we are going to show that it is equal to  $r$ , but suppose it is some integer  $n$ , but that means,  $\sigma^n$  is identity,  $\sigma^n$  is the identity element of the Galois group, which means it is identity automorphism.

So,  $\sigma^n(\alpha) = \alpha$  for all  $\alpha$  in  $K$ . So, this implies. So, maybe I will write it here that means,  $\sigma^n(\alpha) = \alpha$ ,  $P^n$  equals  $\alpha$ , for all  $\alpha$  in  $K$ . That

means,  $\alpha$  is a root of, so  $\alpha$  is a root of that polynomial  $X^{p^n} - X$  in  $K$ . Since, degree of  $X^{p^n} - X$  is equal to  $p^n$ ,  $X^{p^n} - X$  has at most  $p^n$  roots.

See, this is a statement for any field. So, if you have a field, so this is a general statement. Let us say  $f$  is a polynomial in  $K[X]$ , degree  $f$  is  $n$ .  $f$  has at most  $n$  roots in  $F$ , because you can, every time you have a root  $\alpha$ ,  $X - \alpha$  will divide, if you have a root  $\alpha$ ,  $X - \alpha$  divides  $f$ . So, you can divide by it and get a degree  $n - 1$  polynomial, which will have induction at most  $n - 1$  roots.

So this is a statement that we generally have over a field. It is important that it is a field, it is not true for a ring,  $F$  must be a field. So,  $F$  must be a field. In this case it has  $p^n$  roots, on the other end every element of  $K$  is a root of  $X^{p^n} - X$  that is the statement.

$\alpha$  is a root of this for all  $\alpha$  and  $K$ , because for all  $\alpha$  and  $K$ ,  $\alpha^{p^n} = \alpha$  is equal to  $\alpha$ . So, that means the number of elements of  $K$  must be less than or equal to the number of roots of  $X^{p^n} - X$ . So, that means number of elements of  $K$ , which is  $p^r$  which is less than or equal to the degree of the polynomial, which is  $p^n$ . So, that means  $r$  is equal to  $n$  is at least  $r$ .

So, that means, the order is at most order is at least  $r$ , but we do know that  $\sigma^{p^r}$  of  $\alpha$  is  $\alpha^{p^r}$ , which is  $\alpha$ , this is because elements of  $K$  are roots of, this is from the structure theorem of finite fields. So every element of  $K$  is a root of  $X^{p^r} - X$ . So, it must satisfy  $\alpha^{p^r} = \alpha$ .

So, this must be the case. So, this implies order of, so this implies  $\sigma^{p^r}$  is identity. So, order is less than or equal to  $r$ . Order is the smallest positive integers such that this has property. So, which is  $n$ , so hence,  $N$  is less than equal to  $r$  as well as greater than equal to  $r$ . So order is equal to  $r$  by this analysis, so that proves the claim.

So that means the subgroup generated by  $\sigma$  in the Galois group has order  $r$ . So, the if, you have an order  $r$  element, the subgroup generated by that is equal to  $1, \sigma, \sigma^2$  and so on. And it will go up to  $\sigma^{r-1}$ , that has order  $r$ . So, this is order now, let us just see where we are. So, in particular, order of the Galois group, let us call this  $G$  for

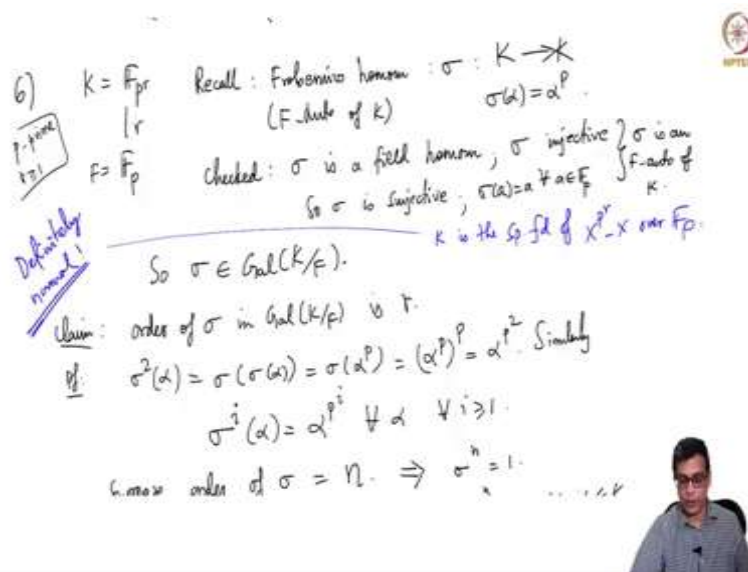

simplicity is at least  $r$  because it has a subgroup or not, so number of elements in  $r$  itself must be at least  $R$ .

So, now, let us write down this following set of inequalities. So,  $r$  we know very well is the degree of this field extension  $FPr$  or  $FP$ , but this is greater than or equal to the -- because  $FPr$  is here, the fixed field will be somewhere here and this is  $FPr$ , sorry  $FP$ . So, the fixed field always contains  $FP$ ,  $FP$  being the prime field or more directly any automorphism in the Galois group must fix  $FP$ .

So, this is something we have, but this by the various theorems that we proved about fixed fields is precisely the cardinality of  $G$ , but that we know is at least  $r$ , so we have  $r$ , greater than equal to  $r$ , so everything in the middle is equal to  $r$ . So hence, the only possibility is  $FPr$  colon  $FPrG$  is  $r$ . That means  $FPr$  fixed field over  $FP$  is 1. So, if this is  $r$ , this is 1, because the whole thing is  $r$ .

That means, any degree one extension means they are equal. So, the fixed field is  $FP$ . So, hence, it is not a Galois. So, it is a fixed field. So, the cardinality of the Galois group is  $r$  is in fact, more we can say it is the cyclic group generated by  $\sigma$ . So, it is cyclic group of order  $r$ . And of course, it is always normal, I should have said this at the very beginning, this is normal.

(Refer Slide Time: 10:08)

6)  $K = \mathbb{F}_{p^r}$   
 $\downarrow$   
 $F = \mathbb{F}_p$

Recall: Frobenius automorphism:  $\sigma: K \rightarrow K$   
 $\sigma(x) = x^p$   
 (F-autom of  $K$ )

Checked:  $\sigma$  is a field automorphism,  $\sigma$  is injective  
 $\sigma$  is surjective,  $\sigma(a) = a \forall a \in F$   
 $\sigma$  is an F-autom of  $K$ .

So  $\sigma \in \text{Gal}(K/F)$ .

Claim: order of  $\sigma$  in  $\text{Gal}(K/F)$  is  $r$ .

Proof:  $\sigma^2(\alpha) = \sigma(\sigma(\alpha)) = \sigma(\alpha^p) = (\alpha^p)^p = \alpha^{p^2}$ . Similarly  
 $\sigma^i(\alpha) = \alpha^{p^i} \forall \alpha \forall i \geq 1$ .

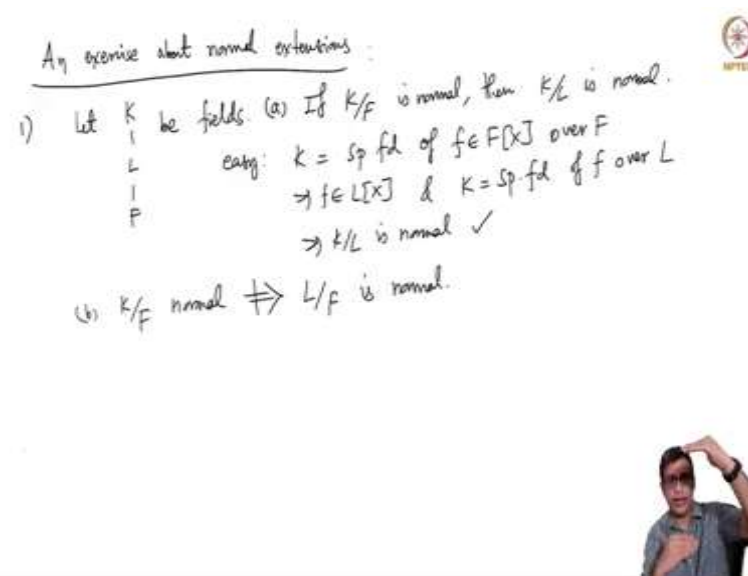

hence order of  $\sigma = r \Rightarrow \sigma^r = 1$ .

*Definitely normal!*

*K is the splitting field of  $x^{p^r} - x$  over  $F_p$ .*

This is normal because of the structure theorem, because this  $K$  is a splitting field of, let me just squeeze that here  $K$  is the splitting field of  $X$  power  $P$  power  $r$  minus  $X$  over  $F_p$ . So, it is a splitting field of a polynomial. So it is normal, it is also Galois and its Galois group is cyclic, that is the observation.

(Refer Slide Time: 10:44)

Any exercise about normal extensions:

1) Let  $K$   
 $\downarrow$   
 $L$   
 $\downarrow$   
 $F$  be fields. (a) If  $K/F$  is normal, then  $K/L$  is normal.

easy:  $K = \text{Sp. fld. of } f \in F[X] \text{ over } F$   
 $\Rightarrow f \in L[X]$  &  $K = \text{Sp. fld. of } f \text{ over } L$   
 $\Rightarrow K/L$  is normal  $\checkmark$

(b)  $K/F$  normal  $\Rightarrow L/F$  is normal.

Now, let me do an exercise about normal extensions. So, I will give you a few properties of normal extensions in this exercise. So let me make a few statements and while we will prove that one by one. So, one, let  $K/F$  be fields, if  $K$  over  $F$  is normal, then  $K$  over  $L$  is normal. So, this is because this is the first point, a, let us say.

This is easy, because  $K$  is a splitting field of, by one of the equivalent conditions for a normal extension,  $K$  is the splitting field of let us say  $f$  in  $F[X]$  over  $F$ , but that polynomial lives in  $F[X]$ . So,  $f$  is also in  $L[X]$  and  $K$  is the,  $K$  will continue to be the splitting field. There is no problem because it is generated by the roots over  $F$ , so it is also generated by the roots over  $L$ . So, this implies that  $K$  over  $L$  is normal. No problem, but it is not true, does not imply  $L$  over  $F$  is normal.

(Refer Slide Time: 12:22)

Handwritten notes on a slide:

At the top:  $I$   $P$

→  $f \in L[X]$  a ...

→  $K/L$  is normal ✓

(b)  $K/F$  normal  $\Leftrightarrow L/F$  is normal: eg

normal

Show that  $K$  is the sp. fld of  $X^4 - 2$  over  $Q$

not normal

(c)  $K/L, L/F$  normal  $\Leftrightarrow K/F$  normal: eg

not normal

normal (deg 2)

normal

So, in general, if you have a tower of three fields, the bigger  $X$ , that top over bottom is normal implies, the top half is normal, bottom half is not in general normal. And the reason is example is you can simply take  $Q$ , adjoin fourth root of two comma  $i$  to  $Q$  adjoined fourth root of 2 to  $Q$ . So, this is not normal we know. This came up in the previous problem, because it is not a splitting field, rather  $X^4 - 2$  has a root in this, but not all the roots, this is not normal, however, this is normal.

So, I will let you prove this for yourself. Show that, so here it is  $K$ , this is  $L$ , this is  $F$ , show that  $K$  is a splitting field of  $X^4 - 2$  over  $Q$ . And the reason that  $L$  fails to be normal is because it is missing roots. And once you provide those roots it will become normal. So, in fact, every field extension can be extended to a normal extension as I do in a problem a little bit later.

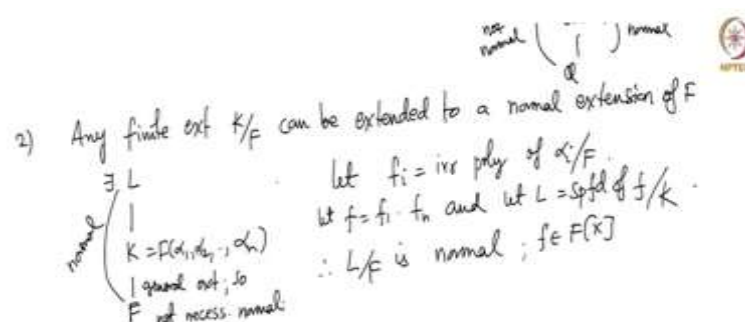

So, the bigger top to bottom is normal and this is normal of course, by the first part, but this is not normal. So, that is – that can happen. And finally, if  $K$  over  $L$  is normal, and  $L$  over  $F$  normal, does not mean  $K$  over  $F$  is normal. So, if you have three fields, one above other, and

the both halves of the tower are normal does not mean the entire tower is normal. And this example is you take  $\mathbb{Q}$  adjoined fourth root of 2 over  $\mathbb{Q}$  adjoined square root of 2 over  $\mathbb{Q}$ .

This is normal by because it is a degree to extension. This is also normal, these are both degree 2. And by one of the properties of something I did in the previous set of problems, any degree to extension of fields is normal. So these are both normal, but this is of course not normal by that came up earlier also. So normal extension followed by another normal extension may not imply that the entire extension is normal.

(Refer Slide Time: 14:47)

So, let us analyse these a little bit more to see what we can say about a normal extension. So but let me first get the following clear. So, any finite extension  $K$  over  $F$ , can be extended to a normal extension, by which I mean. So, if you are given a -- So, let us say  $K$  over  $F$  is given. So, write  $K$  as  $F$  of  $\alpha_1, \alpha_2, \alpha_r$  or  $\alpha_n$ .

So, take  $f_i$  to be the irreducible polynomial or let I should write, let  $f_i$  be the irreducible polynomial of  $\alpha_i$  over  $F$ . So, when I say I can extend it I mean that you can find a bigger field  $L$ , which is normal over, so there exists  $L$  is what I am saying, normal extension of  $F$ . So, then you take  $F$  to be  $F_1$  times  $F_n$  and let  $L$  be the splitting field of  $F$  over capital  $F$ .

Because or you can take over capital  $K$ , no problem. So, it is a splitting field over capital  $F$ . So, then  $L$  over  $F$  is normal because it is a splitting field of the small  $f$  over capital  $F$ , because  $f$  is a polynomial in  $FX$  and it is generated by the roots. So, any extension can be extended to,

this is not, this is a general extension, so not necessarily normal. So, this is not necessarily normal, but you can always put it inside a normal extension.

(Refer Slide Time: 17:00)

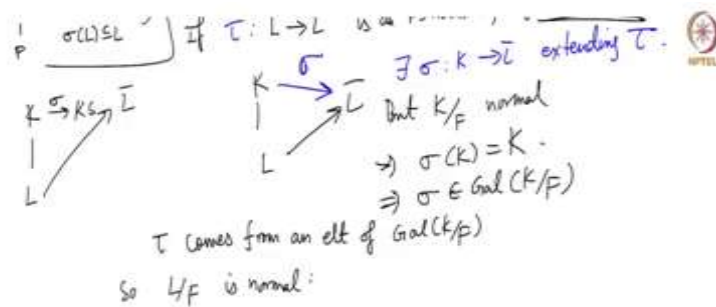

3)  $\begin{matrix} K \\ | \\ L \\ | \\ F \end{matrix}$  Suppose  $K/F$  is normal. (already know  $K/L$  is normal).  
 Then  $L/F$  is normal  $\Leftrightarrow \sigma(L) \subseteq L \quad \forall \sigma \in \text{Gal}(K/F)$ .  
 Soln: Suppose  $L/F$  is normal, let  $\sigma \in \text{Gal}(K/F)$ .  
 $\Rightarrow \forall \sigma: \begin{matrix} K \rightarrow K \\ | \\ L \end{matrix}$   $\sigma|_L: L \rightarrow K \subseteq \bar{L}$   
 Since  $L/F$  is normal, we know  $\sigma(L) \subseteq L$ .  $\checkmark$

$\Leftarrow$ : Suppose  $\sigma(L) \subseteq L \quad \forall \sigma \in \text{Gal}(K/F)$ .  
 we are given the condition for  $\sigma \in \text{Gal}(K/F)$ .  
 But are there any other maps  $L \rightarrow \bar{L}$ ?  
 If  $\tau: L \rightarrow \bar{L}$  is an  $F$ -homom, by ext theorem,  
 $\exists \sigma: K \rightarrow \bar{L}$  extending  $\tau$ .  
 $\begin{matrix} K & \xrightarrow{\sigma} & \bar{L} \\ | & \nearrow & \\ L & & \end{matrix}$  But  $K/F$  normal  
 $\Rightarrow \sigma(K) = K$ .  
 $\Rightarrow \sigma \in \text{Gal}(K/F)$

$\begin{matrix} L \\ | \\ F \end{matrix} \xrightarrow{\tau} \bar{L}$  we must check  $\sigma(L) \subseteq L$

Theorem: Let  $K/F$  be a finite extension. Let  $\bar{F}$  be an algebraic closure of  $F$  that contains  $K$ . Then the following are equivalent.

- (1) If  $\sigma: K \rightarrow \bar{F}$  is an  $F$ -homomorphism of fields, then  $\sigma(K) \subseteq K$ .  
 Hence:  $\sigma$  induces an  $F$ -automorphism  $\sigma: K \rightarrow K$ .
- (2) If  $f \in F[x]$  is an irreducible poly which has a root in  $K$ , then  $f$  splits completely in  $K[x]$ .
- (3)  $K$  is the splitting field of a poly  $f \in F[x]$ .

pf: (1)  $\Rightarrow$  (2): Let  $f \in F[x]$  be an irr poly and let  $\alpha \in K$  be a root of  $f$  in  $K$ . We know that  $f$  splits completely in  $\bar{F}[x]$ .

If  $K/F$  is algebraic and  $\sigma: K \rightarrow K$  is an  $F$ -homomorphism, then  $\sigma$  is surjective i.e.,  $\sigma(K) = K$  — previous exercise

23:01, 23:24 So now finally, let me do one more feature of Galois extensions. So, let us take a tower of fields, let us take  $K \supset L \supset F$ . So, these are extensions and let us suppose that  $K$  over  $F$  is normal. And let us take. So, what I want to say is that suppose this, so suppose  $K$  over  $F$  is normal, we already know,  $K$  over  $L$  is normal. But in general  $L$  over  $F$  is not normal, but when is it normal? So, that is what I want to say.

Then there are all finite extensions. By the way, everything I am doing is finite extensions. Sometimes it may be true in general, but I do not want to deal with infinite extension. So, everything I am doing is a finite extension, normal Galois extensions for me are always finite, then  $L$  over  $F$  is normal if and only if the following happens,  $\sigma(L)$  is contained in  $L$  for all  $\sigma$  in the Galois group of  $K$  over  $F$ .

So, this is what I want to show. So, why is this? I want to show that  $L$  over  $F$  is, so in general  $L$  over  $F$  is not normal as this example shows here, but it is normal if this condition is satisfied. So, let us check this. So, suppose  $L$  over  $F$  is normal, suppose  $L$  over  $F$  is normal, then let us take  $\sigma$  in the Galois group of  $K$  or  $F$ .

So, then if you restrict, so  $\sigma$  is a function from  $K$  to  $K$ , but  $L$  is here, so you can restrict to  $L$ , that will be a function from  $L$  to  $K$ , we do not know a priori that  $L$  image of something in  $L$  again in  $L$  but it is in  $K$ . However, remember the one of the conditions for a normal extension, which I did way back is that any map from  $K$  to  $\bar{F}$  has the property that image lands again in  $K$ .

So,  $\sigma$  restricted to  $L$  is a function from  $L$  to  $\bar{L}$  because  $K$  obviously is contained in  $\bar{L}$ . Since  $L$  is normal over  $F$  we know  $\sigma L$  is contained in it. So because this is the equivalent condition for normality, so this is okay now, so let us prove this condition. This is exactly the same condition. Because suppose  $\sigma L$  is contained in  $L$  for all  $\sigma$  to prove, this is normal, let us do the following. So, what am I supposed to do? Yeah, so this is normal, but this any.

So, to check normality, what we have to check is you give me any map from  $L$  to  $\bar{L}$ , we must check, yeah, so this is essentially given any such maps, we must check  $\sigma L$  is contained in  $L$ . So, what we are given is that, we are given this condition for  $\sigma$  in Galois group, but can we show this for any map from  $L$  to  $\bar{L}$ ? So, let us take, but are there others, I will write.

Are there any other maps from  $L$  to  $\bar{L}$ , I claim there are none, because if  $\tau$  from  $L$  to  $\bar{L}$  is a field homomorphism, is  $F$  homomorphism by extension theorem. So,  $L$  to  $\bar{L}$  is given, and  $K$  is a finite extension this there is an extension like this. There exists  $\tau$ , this is  $\sigma K$  to  $\bar{L}$  extending  $\tau$ , but this is by extension theorem, but  $K$  over  $F$  is normal implies  $\tau$  of  $K$  is contained, in fact equal to  $K$ .

Because normal Extension has that property, any map from  $K$  to an algebraically close field must have this equal image, must be equal to  $K$ . So, that means  $\sigma$  must be a priori an element of the Galois group. So  $\tau$  must come from, so  $\tau$  comes from an element of, I am sorry, I am going on this very fast. But I want to do one more example. So, I wanted to quickly finish this, but please pay close attention.

If you have any math from  $L$  to  $\bar{L}$ , it must come from, it must come from a Galois group element. So, and for those, we have this condition, so that means  $L$  over  $F$  is normal, again by our main theorem about normal extensions. So, in general, if you take a tower of fields, in the top to bottom is normal, the bottom half is not necessarily normal and this gives you a condition for checking the normality.

(Refer Slide Time: 23:44)

4)  $K/L$ ,  $K/F$ ,  $K/L$ ,  $L/F$  are all normal. Then we have an "exact sequence" of groups:

$$1 \rightarrow \text{Gal}(K/L) \xrightarrow{\psi} \text{Gal}(K/F) \xrightarrow{\varphi} \text{Gal}(L/F) \rightarrow 1$$

exact seq: ①  $\psi$  is inj ✓

②  $\text{Im } \psi = \ker \varphi$

③  $\varphi$  is surj

$\sigma \in \text{Gal}(L/L)$   
 $\sigma: K \rightarrow K$ ,  $\sigma|_L = \text{id}$   
 $\Rightarrow \sigma \in \text{Gal}(K/F)$   
 $\psi(\sigma) = \sigma$

What is  $\varphi$ ?

②  $\text{Im } \psi = \ker \varphi$

③  $\varphi$  is surj

What is  $\varphi$ ?

$K \xrightarrow{\sigma} K$   
 $|$   
 $L \xrightarrow{\sigma|_L} L$   
 $|$   
 $F$

$\sigma \in \text{Gal}(K/F)$ .  $\sigma: K \rightarrow K$ , restrict  $\sigma$  to  $L$ .  
 $\sigma|_L: L \rightarrow K$  a priori the image isn't in  $L$ .  
 But since  $L/F$  is normal,  $\sigma|_L(L) \subseteq L$ .  
 $\varphi(\sigma) = \sigma|_L$ .

$$\begin{array}{c}
 L \xrightarrow{\psi} L \\
 \downarrow \text{F} \\
 \text{Gal}(K/F) \rightarrow \text{Gal}(K/L) \rightarrow \text{Gal}(L/F) \\
 \sigma \mapsto \sigma \mapsto \sigma|_L
 \end{array}$$

Now, let me do one final thing. And I want to sort of go over this fast, because I am running out of time. But I will set it up for you to complete this. So, suppose these are normal and everything in the in view is normal. So suppose we have these normal, all of them are normal, then we have an exact sequence. So I do not want to, I mean, maybe this is something that you are not seen before, but exact sequence of groups.

So, let me explain what this is and then we will, I mean, I will explain everything. So, what we have is, I will explain what I mean by an exact sequence. What is an exact sequence? So, I mean that let us give these names. So let us call this  $\psi$  and let us call this  $\sigma$  not  $\psi$ . So, exact sequence means  $\psi$  is injective, image of  $\psi$  is equal to kernel of  $\phi$ . And finally,  $\phi$  is surjective. First of all, what are these maps?

I need to define this. You take an element in the Galois group of  $K$  over  $L$ . So that means it is a function from  $K$  to  $K$ , which fixes  $L$  point wise. But then it implies, it fixes everything in  $F$  point wise. No problem. Everything in  $L$  is fixed point wise, so obviously everything in  $K$  is fixed point wise. So, that means,  $\sigma$  belongs to the Galois group, it is a  $k$  automorphism, automorphism of  $K$  which fixes everything in  $F$ .

So, that means,  $\psi$  of  $\sigma$  is actually just  $\sigma$ , because an element here is an automorphism of  $K$ , but it must fix  $L$  point point wise. Here these are automorphisms of  $K$  that fix  $F$  point wise, but if something fixes  $L$  point wise, it definitely fixes  $F$  point wise. So,  $\psi$  is simply an inclusion and it is certainly an injective map, because if  $\psi$  is non-zero, non-trivial map that means it is not identity, its images  $\sigma$  itself.

So, it is not identity. If  $\sigma$  is not identity, its image, which is again  $\sigma$  is not identity. So, that is okay. What is  $\phi$ ? So, for  $\phi$  we start with an element of Galois  $K$  over  $F$ , that means, it is a function from  $K$  to  $K$ , so restrict  $\sigma$  to  $L$ . So, you have  $K$  here,  $K$  to  $K$  here,  $L$  here,  $F$  here. So, restrict  $\sigma$  to  $L$ , a priori it is to  $K$ , the image is  $K$ , but since, this is the previous problem,  $L$  over  $F$  is normal,  $\sigma L$  of  $L$  is contained in  $L$ .

This is of course, same as  $\sigma L$ . So, this also goes to  $L$ . So, this is the property that it is normal, so it is  $L$  over  $F$  is normal. So, image of any element of  $L$  must go to a conjugate but once  $L$ , element irreducible polynomial has one root in  $L$ , it has all the roots. So, all the conjugates are also in  $L$ . So, this holds. So,  $\phi$  of  $\sigma$  is simply  $\sigma$  restricted to  $L$ .

So, this is just to rewrite everything now, what we have is Galois  $K$  over  $L$  to Galois  $K$  over  $F$  to Galois  $L$  over  $F$ , automorphism of  $K$  which fixes  $L$  pointwise goes through itself and then it goes to  $\sigma$  restricted to  $L$ . This exact sequences have this one at the bottom at the left hand right hands, that is just a notational issue, it simply says that this is injective This is surjective and the at the middle your kernel equals image.

(Refer Slide Time: 28:19)

$$\begin{aligned} \text{let } \sigma \in \text{Gal}(K/F) \text{ be in } \text{Ker } \phi: \text{ So } \phi(\sigma) = \sigma|_L = \text{id} \\ \therefore \sigma(\alpha) = \alpha \quad \forall \alpha \in L \\ \Rightarrow \sigma \in \text{Gal}(K/L) \\ \Rightarrow \sigma = \psi(\sigma) \\ \Rightarrow \text{Ker } \phi \subseteq \text{Im } \psi \end{aligned}$$

$$\Rightarrow \ker \varphi \subseteq \operatorname{im} \psi.$$

•  $\varphi$  is Surj: let  $\sigma \in \operatorname{Gal}(L/F)$   
 Using extension theorems, we  
 can extend  $\sigma$  to  $\tilde{\sigma}: K \rightarrow \bar{L}$ .  
 But  $K/F$  is normal  $\Rightarrow \tilde{\sigma}(K) = K \Rightarrow \tilde{\sigma} \in \operatorname{Gal}(K/F)$ .  $\square$

$$\begin{array}{ccc} K & \xrightarrow{\psi} & K \subseteq \bar{L} \\ | & & \nearrow \\ L & \xrightarrow{\varphi} & L \\ | & & \\ F & & \end{array}$$

4)  $K/F, K/L, L/F$  are all normal. Then we have an "exact sequence" of groups:

$$1 \rightarrow \operatorname{Gal}(K/L) \xrightarrow{\psi} \operatorname{Gal}(K/F) \xrightarrow{\varphi} \operatorname{Gal}(L/F) \rightarrow 1$$

exact seq: ①  $\psi$  is inj  $\checkmark$   
 ②  $\operatorname{Im} \psi = \ker \varphi$   $\checkmark$   
 ③  $\varphi$  is surj  $\checkmark$

what is  $\varphi$ ?  $\sigma \in \operatorname{Gal}(K/F)$ .  $\sigma: K \rightarrow K$ , restrict  $\sigma$  to  $L$ .  
 $\sigma|_L = \text{a priori the image}$

$\sigma \in \operatorname{Gal}(L/L)$   
 $\sigma: K \rightarrow K$ ,  $\sigma(\alpha) = \alpha$   $\forall \alpha \in L$   
 $\Rightarrow \sigma \in \operatorname{Gal}(K/F)$   
 $\varphi(\sigma) = \sigma$

So, now, we have checked that  $\varphi$  is injective and let me quickly tell you how to check kernel of  $\varphi$  equals image of  $\psi$ . So, suppose,  $\sigma$  is an image  $\psi$ . So, really there is not much here, it is just a matter of keeping track of the notation. That means, it comes from an element of the Galois group of  $K$  over  $L$ . So,  $\sigma$  restricted to  $L$  is identity because it fixes  $L$  point wise. So,  $\sigma$  restricted  $L$  is identity that means,  $\varphi(\sigma)$  is identity. So, image  $\psi$  is contained in kernel  $\varphi$ . So, if something comes from  $\psi$ , it must map to identity.

So, that means, it is in the kernel of this map. So, on other end, suppose something is in the kernel of  $\varphi$ , so let  $\sigma$  be in the image of  $\psi$ , sorry,  $\sigma$  be the Galois group of  $K$  over  $F$ , be in the kernel of  $\varphi$ . So,  $\varphi(\sigma)$  restricted to  $L$ , which is exactly, sorry,  $\varphi(\sigma)$  which is  $\sigma$  restricted to  $L$  is identity. That means, if you spell that out,  $\sigma(\alpha) = \alpha$  for all  $\alpha$  in  $L$ . So,  $\sigma$  is in the Galois group of  $K$  over  $L$ . So,  $\sigma$  is equal to  $\psi(\sigma)$ .

So, this implies in a kernel of  $\phi$  is contained in image of  $\psi$ , image of  $\psi$  is contained in kernel of  $\phi$ .

So, the second condition is also okay. Finally, we have to check the third one which is that  $\phi$  is surjective and this is just an extension theorem statement. So, let  $\sigma$  be in the Galois group of  $L$  over  $F$ . So, that means it is a function from  $L$  to  $L$ , but then anything like this, of course, maps to  $\bar{L}$  which is  $\bar{K}$ , so you can extend it to  $K$ . But this extension, because  $K$  is normal over  $F$  must land this. So, using extension theorem and this guy sort of came in the previous part.

We can extend, so this is  $\sigma$  tilde,  $\sigma$  to  $\sigma$  tilde from  $k$  to  $\bar{L}$  a priori, but  $k$  over  $L$  is normal or  $K$  over  $F$  is normal, because remember everything here is a  $F$  homomorphism. So, base field is important,  $K$  over  $F$  is normal implies  $\sigma(K) = K$ . So,  $\sigma$  tilde is an element of, remember because it is an  $F$  homomorphism it fixes  $F$  point wise, so it is an element of the Galois group of  $K$  over  $F$ .

So, everything so, that and further let me write one more line. So,  $\phi$  of  $\sigma$  tilde is  $\sigma$  implies  $\phi$  surjective. So, this proves that  $\phi$  is surjective. This is a nice thing to keep in mind. We have, this tells you if you have a tower of three fields, how the three Galois groups in question, you have Galois group of the entire thing, Galois group of the top extension, Galois group of the bottom extension.

So, there is an exact sequence where the middle thing is the Galois group of the entire extension, top to bottom, left is a Galois group of the top most extension, right side is the Galois group at the bottom extension, and they fit in in this nice picture. So, I wanted to do this because it is important for us when we start talking about main theorem of Galois theory.

So let me stop this video here. I hope these two problems sessions gave you an idea of how to solve problems about Galois extensions, normal extensions. In particular, we learned about several Galois extensions, several extensions when and computed their Galois groups and determined whether they are Galois or not, and whether they are normal or not. And then we learned about some properties of normal extensions. So, let me stop this video here. In the next video, we will continue our study of Galois extensions. Thank you.
