Lecture 20
Characterization of Galois Extensions – Part 1

(Refer Slide Time: 00:23)

The next theorem gives us a very convenient way to check if a finite extension K/F is Galois or not.

Theorem: Let K/F be a finite extension. Then K/F is Galois
 $\Leftrightarrow K$ is the splitting field of a separable polynomial over F .

$\Leftrightarrow K$ is the splitting field of a separable polynomial over F

Pf: $\Rightarrow$: Suppose that K/F is Galois; let $G = \text{Gal}(K/F)$.
 Let $G = \{\sigma_1, \sigma_2, \dots, \sigma_n\}$.
 K
 Initial By our earlier results: $F = K^{\text{Gal}(K/F)} = K^G$
 $K^G = F$ $\cdot [K:F] = |G| = n$

Welcome back, we are ready to prove this very important theorem about Galois extensions. And which as I said in the last video, which gives us a convenient way of verifying if something is Galois or not. So, let us get right to the proof. So, you have the statement that a given extension is Galois if and only if the extension field is a splitting field of a separable polynomial over the base field.

So, let us prove first the direction forward direction. So, suppose, so here we are assuming that suppose that K over F is Galois, we are going to show that it is a splitting field of a separable polynomials over capital F . So, suppose that K over F is Galois and let us for convenience called the Galois group G . So, G is the Galois group and write G as $\sigma_1, \sigma_2, \dots, \sigma_n$. So, this mean, it is a finite extension.

In fact, what we know is that, so by our earlier results before we did separability, when we talked about Galois extensions, and Kuru characters, and so on. So, we have this, so this is of course $K^G = F$, so this is the first statement, F is the fixed field of G , and also, the degree of the field extension is order of G , which I am calling n . So, you have a extension like this. And this n is also the cardinality of G . So, that is what we have.

(Refer Slide Time: 02:04)

Pf: $\Rightarrow$ Suppose that K/F is Galois, let $G = \text{Gal}(K/F)$.

Let $G = \{\sigma_1, \sigma_2, \dots, \sigma_n\}$.

K
 $|G| = n$
 $K^G = F$

By our earlier results: $F = K^{G} = K^G$ It is possible that $v < n$

$[K:F] = |G| = n$

Let $\alpha \in K$ be any element. Consider $S = \{\alpha_1, \alpha_2, \dots, \alpha_r\}$

Where S is the set of distinct elements among $\sigma_1(\alpha), \sigma_2(\alpha), \sigma_3(\alpha), \dots, \sigma_{n-1}(\alpha), \sigma_n(\alpha)$

eg:
 $K = \mathbb{Q}(\sqrt{2}, i)$
 $F = \mathbb{Q}$
 $\sigma_1, \sigma_2, \sigma_3, \sigma_4$
 $\sigma_1(\alpha) = \alpha, \sigma_2(\alpha) = i\alpha, \sigma_3(\alpha) = -\alpha, \sigma_4(\alpha) = -i\alpha$

Let $\alpha \in K$ be any element. Consider $S = \{\alpha_1, \alpha_2, \dots, \alpha_r\}$
 Where S is the set of distinct elements among
 $\sigma_1(\alpha), \sigma_2(\alpha), \sigma_3(\alpha), \dots, \sigma_{n-1}(\alpha), \sigma_n(\alpha)$
 claim: G acts on S (i.e., G permutes S)
 or, more precisely: for $\sigma_k \in G$, the function
 $\sigma_k: S \rightarrow S$
 $\alpha_i \mapsto \sigma_k(\alpha_i)$
 is bijective:
 exactly, you know,
 the scenario is.

Example:
 $K = \mathbb{Q}(\sqrt{2}, i)$
 $F = \mathbb{Q}$
 $G = \{1, \sigma_1, \sigma_2, \sigma_3\} \cong \mathbb{Z}_2 \times \mathbb{Z}_2$
 $\alpha = \sqrt{2}; S = \{\sqrt{2}, -\sqrt{2}\}$
 $r = 2 < 4 = n$

So, now, I am going to consider an arbitrary element of capital K, let alpha be an element of capital K, be any element. So, I want to consider the set S to B alpha 1, which is alpha, alpha 2 and alpha r, where S is the set of distinct elements among all the elements that you get by applying G to alpha. So, sigma 1 alpha, sigma 2 alpha, sigma 3 alpha, sigma n minus 1 alpha, sigma n alpha, The point is some of these could be equal to each other.

So, I am going to just take the distinct ones among them and call this r. So, it is possible often that r is less than n. So, for example, I will do one example here. So the proof is very easy, but it is long. So just keep track of it with me and carefully follow the arguments. So, I will give you an example here of what is going on here. So we take a to b, Q root 2 comma i over F, which is q. So here G of course, is something that you have seen many times in the past, it is isomorphic to Z mod 2 cross Z mod 2.

But if you take alpha to be root 2 the set S, you will simply get root 2 comma minus root 2. So r in this example is 2, which is less than 4 which is n. So for a particular element, for example, in this example, you get identity of alpha, which is root 2, sigma, 1 of alpha, I mean, the labelling is somewhat mixed up, but root 2 goes to root 2 under one of them, so that will not give you a new element, whereas in the second one it will go to minus root 2, in the third one, also go to minus root 2.

So remember, this, what we do know however, is that all these are conjugates of alpha, because their images under automorphisms, which fixed capital F. So these are distinct elements. So now in general, I have r less than n. So, let me continue the proof now, so I do not care what r is, but it is smaller than less than or equal to n.

Now, we claim that g acts on S . So in the language of group actions that you would have seen, we said G acts on S , that is G permutes S , that is another or more precisely for σ_K in G , the function σ_K from S to S with sends α_i , two σ_K of α_i is bijective. This is what my claim is. So, if you fix the σ_K , so G remember is σ_K 1 through $\sigma_K n$ take any K between 1 and n .

So, you call that σ_K , then if you have operate σ_K on S , it fixes, it permutes S that means, it is a bijection of S . First of all, why does it even map to S .

(Refer Slide Time: 5:47)

$\bullet \alpha_i \in S$. Then $\alpha_i = \sigma_j(\alpha)$ for some j .
 $\therefore \sigma_K(\alpha_i) = \sigma_K(\sigma_j(\alpha)) = (\sigma_K \sigma_j)(\alpha) = \sigma_k(\alpha) \in S$
 $\therefore \sigma_K(\alpha_i)$ is another element of S . $\sigma_K: S \rightarrow S$.
 of course, this map is injective: $\sigma_K \alpha_i = \sigma_K \alpha_j \Rightarrow \alpha_i = \alpha_j$

$\therefore \sigma_K(\alpha_i)$ is another element of S .
 of course, this map is injective: $\sigma_K \alpha_i = \sigma_K \alpha_j \Rightarrow \alpha_i = \alpha_j$ ($\because \sigma_K$ is an auto)
 $\sigma_K: S \rightarrow S$ is injective $\Rightarrow \sigma_K$ is bijective
 ($\because S$ is finite)

let $f = (x - \alpha_1)(x - \alpha_2) \dots (x - \alpha_r)$
claim: $f \in F[x]$ and f is the irr poly of α over F .

Let $f = (x - \alpha_1)(x - \alpha_2) \dots (x - \alpha_r)$

Claim: $f \in F[x]$ and f is the irr poly of α over F

pf: Let us apply σ_K to f for every $\sigma_K \in G$.

$\sigma_K: k[x] \rightarrow k[x]$
 σ_K is a homom
 $\sigma_K(x) = x$

$$\begin{aligned} \sigma_K(f) &= \sigma_K(x - \alpha_1) \sigma_K(x - \alpha_2) \dots \sigma_K(x - \alpha_r) \\ &= (x - \sigma_K \alpha_1)(x - \sigma_K \alpha_2) \dots (x - \sigma_K \alpha_r) \end{aligned}$$

Claim: $f \in F[x]$

pf: Let us apply σ_K to f for every $\sigma_K \in G$.

σ_K is a homom
 $\sigma_K(x) = x$

$$\begin{aligned} \sigma_K(f) &= \sigma_K(x - \alpha_1) \sigma_K(x - \alpha_2) \dots \sigma_K(x - \alpha_r) \\ &= (x - \sigma_K \alpha_1)(x - \sigma_K \alpha_2) \dots (x - \sigma_K \alpha_r) \\ &= f \end{aligned}$$

$\sigma_K(f) = f \quad \forall \sigma_K \in G$

So, take α_i and s then by definition α_i is equal to, α_i is one of these elements. So, S is this, but each α_i is an element of some σ_j of α , because α_i , they are all elements, images of α under σ_j 's, for some j , therefore, σ_K of α_i , which is the image of this map, σ_K of α_i is equal to σ_K of σ_j of α .

But this is same as σ_K times σ_j of α , by the property that you have a group G . This is a group operation. So, this means σ_K prime α , so this is equal to σ_K prime α , which is another element in this set. So, this must be an element in the set of sets S itself. So, it is not S prime. S consists of all elements like this. So, you apply σ 's and you get S . So, this must be another element of S . So, σ_K α_i prime, α_i is another element of S , maybe same element, but I do not care, it is an element of S .

So, σ_K maps S to S and of course, and of course σ_K this map is injective, because $\sigma_K(\alpha_i) = \alpha_j$ implies $i = j$ because σ_K is an automorphism. This is because it is a field automorphism. In fact, any field homomorphism is injective. So, that is all I need here. So, σ_K is an injective map implies it is also bijective, because S is a finite set.

So, an injective map from S set to itself is bijective, meaning injectivity implies surjectivity and also we have a surjective map from a finite set to itself is also injective. So, to check bijectivity of a finite set map to itself, we need to check either injectivity or surjectivity. So, we check this.

So, this proves this claim σ_K acts on G acts on S . And now, we are able to prove the following statement. So, let $f = x^r - \alpha_1 x^{r-1} + \dots + (-1)^r \alpha_r$. So, remember again, let me remind you, S consists of these elements α_1 through α_r , and they are the distinct set of elements among all the images of α under all elements of G . Again, this is what we are doing in the example.

So, in this example, f will be $x^2 - \sqrt{2}x + \sqrt{2}$. I am not taking all the elements here, I am taking only the distinct elements here. So, the claim is, now this is the most important claim. Claim f is in fact, a polynomial over the base field and f is the irreducible polynomial of α over F . So, this is a very crucial claim.

In fact, it gives us more than what we are claiming in a theorem, it proves the theorem, one direction of the theorem, but it in fact, tells us how to compute irreducible polynomial of an arbitrary polynomial, of arbitrary element. So, why is this? So, first of all why is f in $F[X]$? So note that, so let us apply σ_K to f for every σ_K in G .

So now, I do not want to multiply f out and apply σ_K , I want to keep f as it is and apply σ_K . So what is σ_K of f ? Because σ_K is a group, I mean automorphism σ_K , in fact, gives a map from $K[x]$ to $K[x]$. σ_K induces this, so I am being sloppy and using the σ_K , which is a function from K to K induces this.

Every time you have an automorphism of fields, you get an homomorphism of the polynomial rings in one variable like this, x goes to x and coefficients go to images of σ_K . So, this and σ_K is a homomorphism. So, σ_K of f is actually σ_K of $x^r - \alpha_1 x^{r-1} + \dots + (-1)^r \alpha_r$.

But σ_k of x minus α_1 again using the property that it is a homomorphism and σ_k of x equals x , this will be simply x minus σ_k of α_1 . Similarly, x minus σ_k of α_2 , dot dot dot x minus σ_k of α_r .

Now, just let us stare at this for a moment and use this claim, that G acts on S or more concretely, we have, this is a bijective map, that means, if you apply σ_k to α_1 through α_r , we get a bijection, so, you are permuting the maybe, so if you apply this, this might be in some other, f is this right, this might be the second term, or this might be the first time and so on.

So, I do not care in which order I get, multiplication is abelian. So, this is nothing but f that is a point. So, this is exactly same as f because I get all the factors again. So, σ_k of f is f and of course, this is true for all σ_k in G . So, this is because this I am taking an arbitrary σ_k and f .

(Refer Slide Time: 12:20)

Where S is the set of roots of $f(x) = x^2 - 2$ over $F = \mathbb{Q}$.
 $G = \{ \sigma_1, \sigma_2 \}$ where $\sigma_1(\alpha_i) = \alpha_i$ and $\sigma_2(\alpha_i) = \alpha_j$ for $i \neq j$.
 $\alpha_1 = \sqrt{2}, \alpha_2 = -\sqrt{2}$
 $S = \{ \alpha_1, \alpha_2 \}$
 $r = 2 < 4 = n$
 $f = (x - \sqrt{2})(x + \sqrt{2}) = x^2 - 2$
 $\sigma_k: S \rightarrow S$
 $\alpha_i \mapsto \sigma_k(\alpha_i)$
 is bijective.

So, now, if you go back to this example, and apply σ_k to this, I mean this actually, it is useful to expand this out in this particular example, what you get is x square minus 2, which remember is the irreducible polynomial of root 2 over and the claim is then proved for this example, but the point is if you apply any of these 4 elements of the group you get that polynomial back.

(Refer Slide Time: 12:47)

Hence every coefficient of f is fixed by every elt of G .
 Hence every coefficient of f is in $K^G = F$ Since K/F is Galois.
 $\therefore f \in F[x]$.

Hence every coefficient of f is in $K^G = F$ Since K/F is Galois.
 $\therefore f \in F[x]$. ✓
 Let $g \in F[x]$ be the irr poly of α_1 over F . $\left. \begin{array}{l} f(\alpha_1) = 0 \\ f(\alpha_i) \end{array} \right\}$
 Then Since $f(\alpha) = 0$, g divides f .
 Since $g \in F[x]$ $\Rightarrow g(\alpha) = 0 \Rightarrow \sigma_k g(\alpha) = 0 \quad \forall k=1, \dots, n$
 $\Rightarrow g(\sigma_k(\alpha)) = 0 \quad \forall k=1, \dots, n$
 $\Rightarrow g(\alpha_i) = 0 \quad \forall i=1, \dots, r$.
 $\Rightarrow g$ has atleast r roots.

Let $g \in F[x]$ be the irr poly of α over F . $f(\alpha) = 0$

Then since $f(\alpha) = 0$, g divides f .

Since $g \in F[x]$ $g(\alpha) = 0 \Rightarrow \sigma_k g(\alpha) = 0$
 $\Rightarrow g(\sigma_k(\alpha)) = 0 \quad \forall k=1, \dots, n$
 $\Rightarrow g(\alpha_i) = 0 \quad \forall i=1, \dots, r$
 $\Rightarrow g$ has at least r roots.
 $\Rightarrow \deg g \geq r$
 $\Rightarrow \deg g = r$
 $\Rightarrow g = f$.

$\deg f = r$
 and g divides f
 $\therefore \deg g \leq r$.

$\deg f = r$
 and g divides f
 $\therefore \deg g \leq r$.

$\Rightarrow g = f$
 $\Rightarrow \deg g \geq r$
 $\Rightarrow \deg g = r$
 $\Rightarrow g = f \quad \checkmark$.

This proves the claim.

{ This is a useful way to find the irr poly of an elt in a Galois ext.

K
 $|G| = n$ By our earlier results: $F = K^{Gal(K/F)} = K^{n-1}$ that $v < n$
 $[K:F] = |G| = n$

Let $\alpha \in K$ be any element. Consider $S = \{\alpha_1, \alpha_2, \dots, \alpha_r\}$

Where S is the set of distinct elements among

$\sigma_1(\alpha), \sigma_2(\alpha), \sigma_3(\alpha), \dots, \sigma_{n-1}(\alpha), \sigma_n(\alpha)$

claim: G acts on S (i.e., G permutes S)

or, more precisely: for $\sigma_k \in G$, the function

$\sigma_k: S \rightarrow S$
 $\alpha_i \mapsto \sigma_k(\alpha_i)$

eg

$K = \mathbb{Q}(\sqrt{2}, i)$

$F = \mathbb{Q}$

$G = \{1, \sigma_1, \sigma_2, \sigma_3\} \cong \mathbb{Z}_2 \times \mathbb{Z}_2$

$\alpha = \sqrt{2}$, $S = \{\sqrt{2}, -\sqrt{2}\}$

$r = 2 < 4 = n$

So, the conclusion is hence every coefficient of f . So, now if you expand f out and look at coefficients they must be fixed by every element of G that means, every coefficient of f is in the fixed field of G . A priori f is a polynomial in $K[x]$ that means, every element coefficient of f is in K , but we just argued that because $\sum_{K \in G} K f$ is equal to f .

Remember f is a $n \times n$ plus a $n - 1$ x minus actually r , it is a degree r polynomial, $\sum_{K \in G} K f$ is $\sum_{K \in G} K a_r x^r$ and so on. But these are equal that means, $\sum_{K \in G} K a_r$ equals a_r . So, every question of f is fixed by every element of j that means, every coefficient of f is in K^G , but K^G is equal to F , since K over F Galois.

So, this is the statement that the assumption that K over F is Galois we are going to use that here. So, that means, f is in $F[x]$, if every coefficient of f is in the fixed field and the fixed field is capital F that means, the polynomial itself is in capital $F[x]$. So, this is the first part of the claim. Now, I claim that it is in fact the irreducible polynomial, this is easy.

Let G be the irreducible polynomial of α , so it is a algebraic elements it is, it must have an irreducible polynomial, let us call that G . Then of course, since, $f(\alpha) = 0$, remember α is equal to α^1 and α^1 is a root of f . So, $f(\alpha^1) = 0$. So, G divides f because irreducible polynomial divides every polynomial that has α as a root. So, so far we have concluded that G divides f , but now what can be the degree of G .

So, note that since G has coefficients in F , $G(\alpha) = 0$ implies $\sum_{K \in G} K \alpha^i$ is equal to 0. This is not the reason, I will write what this gives, this is a triviality $\sum_{K \in G} K$ of a 0 element is the 0 element, but this is $G(\alpha)$ of α , this is the reason because $\sum_{K \in G} K$ fixes all the questions of G you can bring $\sum_{K \in G} K$ inside, so $G(\alpha) = 0$ that means, $G(\alpha^i) = 0$ for all i from one to r .

What are α^i 's, let us go back to the beginning of the proof, α^i 's are just the distinct set of elements from $\alpha^1, \alpha^2, \dots, \alpha^n$, $G(\alpha^i) = 0$ for all K from 1 to n . But some of them are equal. So, $G(\alpha^i) = 0$ for all, every i from 1 to r , that means, G has at least r roots.

Remember also that α^i 's are distinct by choice, $\sum_{K \in G} K \alpha^i$ may not be distinct like in this example, but α^i 's are distinct $\sqrt{2} - \sqrt{2}$, because we are only taking distinct ones among these. So, G has at least our roots, that means degree G is at least r ,

because a polynomial which has a roots in a field must have at least degree, but degree of f is r and the g divides f .

So, degree of g is less than or equal to r , but it is also greater than equal to r by which we argued, but that means g is equal to f , because irreducible polynomial is a unique Monic polynomial, which has a least degree, which has α as a root, f is Monic, g is Monic so they are equal. So, this proves the, this proves the claim and in fact, let me comment here that this is a useful way to find the irreducible polynomial of an element in a Galois extension.

Because what you do you take that element and you take the Galois group and you look at all its images and among the images, you take the distinct set and you simply take x minus the first one, x minus the second one, x minus the last one and multiply it out by this claim that will be a polynomial in capital F and it will be the irreducible polynomial. So, that is a side remark. So, what did we show? We showed that f is the irreducible polynomial. So, we are almost done now with forward implication.

(Refer Slide Time: 18:40)

Now note that f has distinct roots in K , namely $\alpha = \alpha_1, \alpha_2, \dots, \alpha_r$. Hence f is separable.
 So α is separable over $F \forall \alpha \in K$
Prmk: We have showed that K/F is separable.
 Let $K = F(\beta_1, \beta_2, \dots, \beta_n)$. (we can do this because K/F is finite)
 $f_i = \text{irr poly of } \beta_i \text{ over } F$. Let $f = f_1 f_2 \dots f_n$
 In the above analysis f_i is sep $\forall i$. Hence so is f .

Prk: We have showed that $\overline{K}/F$ is $\overline{K}$ (we can do this because K/F is finite)

Let $K = F(\beta_1, \dots, \beta_n)$. (we can do this because K/F is finite)
 $f_i = \text{irr poly of } \beta_i \text{ over } F$. Let $f = f_{i_1} \cdot f_{i_2} \cdot \dots \cdot f_{i_n}$

By the above analysis f_i is sep $\forall i$. Hence so is f .

Claim: K is the splitting field of f over F .

Pf: Know that irr poly of β_i over F is $(X - \beta_i)(X - \beta_{i_2}) \dots (X - \beta_{i_n}) \in F[X]$, where each $\beta_{i_j} = \sigma_{\tau}(\beta_i)$ for some $\sigma_{\tau} \in \text{Gal}(K/F)$.

Pf: Know that irr poly of β_i is $(X - \beta_i)(X - \beta_{i_2}) \dots (X - \beta_{i_n}) \in F[X]$, where each $\beta_{i_j} = \sigma_{\tau}(\beta_i)$ for some $\sigma_{\tau} \in \text{Gal}(K/F)$.
 But $\sigma_{\tau}: K \rightarrow K$ is an auto. So $\sigma_{\tau}(\beta_i) \in K$.

of course, this map is injective $\Rightarrow \alpha_i = \alpha_j$ ($\because \sigma_{\tau}$ is an auto)
 $\sigma_{\tau}: S \rightarrow S$ is injective $\Rightarrow \sigma_{\tau}$ is bijective ($\because S$ is finite)

Let $f = (X - \alpha_1)(X - \alpha_2) \dots (X - \alpha_r)$
Claim: $f \in F[X]$ and f is the irr poly of α over F .
Pf: Let us apply σ_{τ} to f for every $\sigma_{\tau} \in G$.
 $\sigma_{\tau}(f) = \sigma_{\tau}(X - \alpha_1) \sigma_{\tau}(X - \alpha_2) \dots \sigma_{\tau}(X - \alpha_r)$
 $= (X - \sigma_{\tau}(\alpha_1))(X - \sigma_{\tau}(\alpha_2)) \dots (X - \sigma_{\tau}(\alpha_r))$
 $\therefore \sigma_{\tau}(f) = f$ $\forall \sigma_{\tau} \in G$

$\sigma_{\tau}: K \rightarrow K$
 induces
 $\sigma_{\tau}: K[X] \rightarrow K[X]$
 σ_{τ} is a homom
 $\sigma_{\tau}(X) = X$
 $f = a_r X^r + a_{r-1} X^{r-1} + \dots + a_0$
 $\sigma_{\tau}(f) = \sigma_{\tau}(a_r) X^r + \dots + \sigma_{\tau}(a_0)$
 $\Rightarrow \sigma_{\tau}(a_i) = a_i$

So, hence, now note that g has distinct roots, let me use f , f is irreducible polynomial, it has distinct roots in K , namely $\alpha_1, \alpha_2, \dots, \alpha_r$ is of course $\alpha_1, \alpha_2, \dots, \alpha_r$ and hence by the definition of separability that I gave in the last video, f is separable. So, hence, α is separable over K , rather f .

Because we remember started with an arbitrary α in K and we concluded that series D , we concluded that its irreducible polynomial is separable, its irreducible polynomial over capital K is separable. So, α is separable over F , though we do not read this for this particular theorem. What we actually, when we will use this in a corollary later, we have showed that K over F is separable.

So, we have started with the Galois extension and we have showed that it is separable because every element is separable. Now, we are not quite done. So, we have to produce a separable polynomial whose splitting field is K . So, now let K is a finite extension of F that is given to us. So, now, let us choose some β_1 through β_n , such that K is equal to, we can do this because K over F is finite that is our global assumption.

So, we have this, by and let us say f_i , f_i is the irreducible polynomial of β_i over capital F and let small f be $f_1 \cdot f_2 \cdots f_n$. By the above analysis f_i is separable for all i , because irreducible polynomial of any element in capital K or F is separable. So, f_i being the original polynomial of β_i is separable hence, so is f because f has irreducible factors just $f_1, f_2, \dots, f_n$ and each of them is separable.

So, f is separable and clearly K is a splitting field, of f over capital F . Because clearly, so now this, I should not say clearly, I will say claim, K is a splitting field. So what is the proof? We know that f is separable. So now we want to show that K is a splitting field. So, we know that irreducible polynomial of β_1 over capital F is of the form $x - \alpha_1, x - \alpha_2, \dots, x - \alpha_{r_1}$, let us say or $(x - \alpha_1)^{e_1} \cdots (x - \alpha_{r_1})^{e_{r_1}}$, I mean the indexing will get quite tricky here, but there will be some number of factors, I do not care what they are.

So, r_1 factors is what I am calling this is because where each β_i , so let me write that here, where so β_i is $\sigma(\alpha_1)$ for some σ in the Galois group. That is exactly this claim. And this claim is extremely important for us. This claim says that, if you take the conjugates of α_1 via capital G , take a distinct set among them and construct this polynomial $(x - \alpha_1)(x - \alpha_2) \cdots (x - \alpha_r)$, what you get is the irreducible polynomial.

So, for β_1 , it would be x minus β_1 , x minus β_1^2 , I mean I do not want to use β_2 because that is already here, that is all, but some things which are images of σ_K , but σ_K is a function from K to K . So, $\sigma_K(\beta_1)$ is in K , this is the most important statement.

(Refer Slide Time: 23:50)

So every root of the irr poly of β_1 over F is in K .
 Hence f_1 splits completely over K .
 Similarly f_i splits completely over $K \forall i$.
 $\therefore f$ splits completely over K , and further K
 is generated by roots of f over F .

K is generated by roots of f over F .
 $\therefore K$ is the splitting field of f over F ; already know
 f is separable. So " $\Rightarrow$ " is proved.

Remark: We really showed: a Galois extension is normal and separable.

$\Leftarrow$:

So, every root of the irreducible polynomial of β_1 over capital F is in capital K , because this is the irreducible polynomial of capital β_1 over capital F and its other roots are simply images of σ_K 's, as you vary σ_K in Galois group, but σ_K is an automorphisms that means, β_1^2 is in capital K , β_1^3 is in capital K , β_1^{r-1} is in capital K , hence f_1 , so by the way this is f_1 in my notation, f_1 is the irreducible polynomial of β_1 .

So, f_1 splits completely over capital K that is the crucial statement because other roots of capital, other roots of f_1 are images of β_1 under the Galois group elements. So, f_1 splits completely. Similarly f_i splits completely. So I hope this is clear. I may have gone over this a little fast, but please go over this carefully and understand if you have questions, you can ask in the discussion forum.

So each f_i split is completely over capital K , so that means f_i split, F splits completely because f is the product of f_1 through f_n , f_1 splits completely up to 2, f_2 splits completely, f_n splits completely, so f does. And remember that you cannot drop any roots of F , K is generated by it is generated by roots of F , because I am going to assume a priori that you can drop none of any of the β_i 's.

If you drop any of the β_i 's, you get a smaller field, that is an implicit assumption here. So that means K is the splitting field of f over capital F and we already showed that that f is separable. So this direction is proved. So we assumed that you have a Galois extension and we proved that K is a splitting field of separable polynomial over the base field.

This is a crucial proof, statement is important, but lot of stuff is going on in this proof. So, I will stop this video in the next video, we will prove the other direction, but what we have really showed here, I want to isolate here is, we really showed that a Galois extension is normal and separable. So, Galois extension is normal and separable, because we have showed here that it is separable and we have just shown below that that it is a splitting field of some polynomial. So it is separable, it is normal rather.

So Galois extension is normal and separable. So in the next video we are going to go the opposite direction, where we are going to suppose that it is a splitting field of a separable polynomial and show that it is a Galois extension. Thank you.
