Main Theorem of Galois Theory – Part 2

(Refer Slide Time: 00:15)

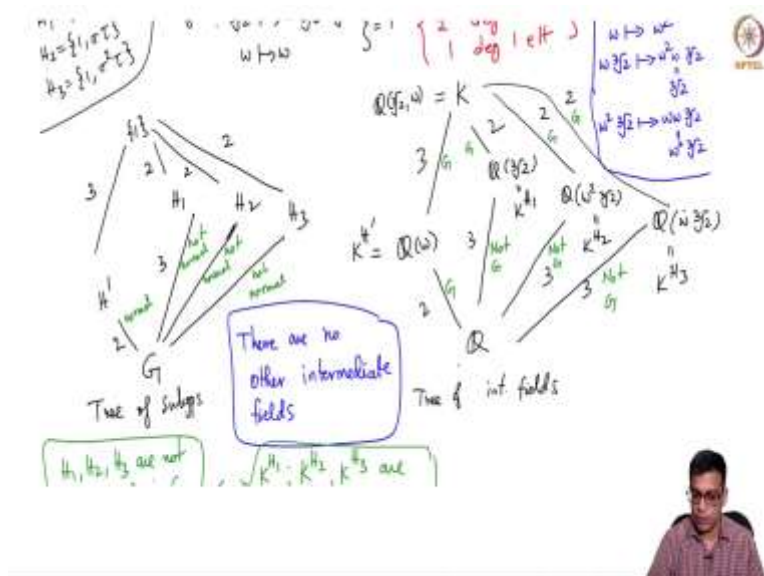

Main Theorem of Galois theory: Let K/F be a Galois extension, and let $G = \text{Gal}(K/F)$ be the Galois group. Then the following hold.

- (1) There is an inclusion-reversing bijective correspondence
- $$\begin{array}{ccc} \{\text{Subgroups of } G\} & \xleftrightarrow{\text{bijection}} & \{\text{intermediate fields of } K/F\} \\ \text{given by} & & \\ H & \longmapsto & K^H \\ \text{Gal}(K/L) & \longleftarrow & L \end{array} \quad \left| \begin{array}{l} H_1 \supseteq H_2 \Rightarrow K^{H_1} \subseteq K^{H_2} \\ \text{Gal}(K/L_1) \subseteq \text{Gal}(K/L_2) \Leftrightarrow L_1 \supseteq L_2 \end{array} \right.$$
- Moreover, this correspondence satisfies:
- $$|H| = [K : K^H] \quad \text{and} \quad [G : H] = [K^H : F]$$
- $\therefore L \dots \text{now } F \Leftrightarrow \text{Gal}(K/L)$

- (2) An intermediate field L is Galois over $F \Leftrightarrow \text{Gal}(K/L)$ is a normal subgroup of G . In this case, we have
- $$\text{Gal}(L/F) \cong G / \text{Gal}(K/L)$$

K
 $|H|$
 K^H
 $|G:H|$
 F

$\text{Gal}(K/L)$ is Galois
 F is Galois

Welcome back, we are in the middle of proving this main theorem of Galois Theory and this is really the first main result in this course. In fact, as the name itself suggests, this is the main theorem of Galois Theory. So, everything that we do later will build on this. So, this is a good point to take stock of the course and see that you are following everything.

So, I in the last couple of videos, I recalled the basic things, and set up the main theorem by giving you a few examples and in the last video, we stated this and proved part of it. So, main theorem of Galois Theory tells you a lot about Galois extensions. And the first statement we proved last time is that there is a bijection between subgroups of G and intermediate fields of the given extensions.

But G is of course, a Galois group. And this inclusion this bijective correspondence in fact, is an inclusion reversing one. And it you can completely determine the degrees of the extension fields using the order and the index of the subgroups in question. And now today we going to prove this second part.

Second part tells us when the bottom part of the extension is Galois, in general, as we know, if you are given an extension, Galois extension K over L F and you take an intermediate field L , if this is Galois, this is Galois always, but this need not be Galois. As for example, the second example that we did here shows K or Q is Galois here; K is Q adjoined cube root of 2ω but cube root of 2 over Q is not Galois.

(Refer Slide Time: 02:30)

[illegible]

$$F \cong \mathbb{Q}(x, y, w) \xrightarrow{\sigma} L$$

$$L = \mathbb{Q}(x, y, w) \rightarrow \mathbb{Q}(x, y, w)$$

$$\downarrow$$

$$\mathbb{Q}$$

pp: $\frac{\sigma(L)}{\sigma(L)} = \frac{\sigma(L)}{\sigma(L)}$

let $T \in H, \sigma \in \sigma_L$
 $(\sigma \in L)$

Then $(\sigma T \sigma^{-1})(\sigma \alpha) = (\sigma T)(\sigma^{-1} \sigma \alpha) = (\sigma T)(\alpha) = \sigma(T \alpha)$

$$\begin{array}{l}
 L = \text{some } \dots \rightarrow \dots \\
 \text{let } \tau \in H, \sigma \alpha \in \sigma L \\
 (\alpha \in L) \\
 \text{Then } (\sigma \tau \sigma^{-1})(\sigma \alpha) = (\sigma \tau)(\sigma^{-1} \sigma \alpha) = (\sigma \tau)(\alpha) = \sigma(\tau(\alpha)) \\
 \therefore \boxed{(\sigma \tau \sigma^{-1})(\sigma \alpha) = \sigma \alpha} \quad \begin{array}{l} \text{auto of } K \\ \sigma L = \{\sigma \alpha \mid \alpha \in L\} \end{array} \\
 \tau \in \text{Gal}(K/L) \} \Rightarrow \tau \alpha = \alpha \text{ and } \alpha \in L
 \end{array}$$

$$\sigma \tau \sigma^{-1} \in \text{Gal}(K/\sigma L) \quad \forall \tau \in H$$

$$\begin{array}{l}
 \sigma \tau \sigma^{-1} \in \text{Gal}(K/\sigma L) \quad \forall \tau \in H \\
 \text{Hence } \sigma H \sigma^{-1} \subseteq \text{Gal}(K/\sigma L) \quad \text{These are in fact equal}
 \end{array}$$

So, let us take now, an intermediate field. Let L be an intermediate field of the extension, given extension K over F . So this L a priori is just an arbitrary extension, we do not arbitrary intermediate field, we do not know whether it is Galois or F or not. So, I want to define the corresponding group by H denote the corresponding group by H . So, K, L, F in the corresponding group is H . So, this is of course, a subgroup of G , which I will recall for you is the Galois group of the original extension and then, I claim the following.

So, I claim that let σ be in G . So, G is the Galois group of the entire extension, then σ remember, if σ , so I will write that here σ is in G means σ is a function from K to K and L is here F is here, σ fixes F pointwise. But L we do not know, σL is some other

subfield. So, a priori σL is something else, for example, in the field, keyword joint cube root of 2.

Maybe I will write it here. So, Q adjoined cube root of 2 ωQ adjoined cube root of 2 Q , if you call this L and you take a suitable σ which sends cube root of 2 to ω cube root of 2 σL will be Q adjoined cube root of 2 ω . So, σL is some other field. So, σL and it is some other extension, sorry, I should keep this as it is.

So, σL is another intermediate field. The statement that I want to say is that the Galois group of K over σL is σH , σ inverse. So, this is the claim. So, let me prove this is an easy statement. So, the correct way to draw this picture will be I will keep it here. So, L is here, σL is here and F is here.

Why do I say that σL is a subfield of K ? That is because note that σL is inside K so, that it is a subfield because K is Galois or more generally, I mean actually more precisely σ is an automorphism of K . It may not be in L , but it is certainly in K because σ maps K to K . So, we have this picture, I am saying that this Galois group here is this conjugate $\sigma H \sigma$ inverse, you begin to see where normality of H will enter the picture.

Because this is a conjugate of H , H if H is normal this is equal to H . So, now, let us pick something in let us pick something in H let us a τ is in H and let us take an arbitrary element of σL that means, it is image of something in L σL is exactly things like this, by definition, it is the image of L under σ .

So, let us take an arbitrary element like this, then let us apply $\sigma \tau \sigma$ inverse to σL , then $\sigma \tau \sigma$ inverse applied to σL will be $\sigma \tau \sigma$ inverse, this is just a composition of functions. This is $\sigma \tau$ of α , because σ inverse σ of α is this. But $\sigma \tau \alpha$ is this but τ is an H α is an L , where is τ this is the Galois group of K over L , H is by definition Galois group of K over L .

So, everything in H fixes everything in L . So, $\tau \alpha$ is α . So, this is $\sigma \alpha$ that means, $\sigma \tau \sigma$ inverse $\tau \alpha$ $\sigma \alpha$ is $\sigma \alpha$. So, $\sigma \tau \sigma$ inverse belongs to Galois K over τL . Because, basically what I have done by this calculation is you give me anything in σL , you give me any element in σL , it must be of the form

$\sigma\tau\sigma^{-1} \in \text{Gal}(K/\sigma L) \forall \tau \in H$
 Hence $\sigma H \sigma^{-1} \subseteq \text{Gal}(K/\sigma L) \rightarrow (*)$

These are in fact equal
 $L \subseteq \sigma L$ as fields $\Rightarrow L \subseteq \sigma L$ as F -vector spaces
 $\Rightarrow [L:F] = [\sigma L:F]$
 $\Rightarrow [K:L] = [K:\sigma L]$

general group theory fact
 $|\sigma H \sigma^{-1}| = |H|$

K/L is Galois \rightarrow "
 $|H| = |\text{Gal}(K/L)|$

Also know: $|\text{Gal}(K/\sigma L)| \leq [K:\sigma L] = |H|$
 \hookrightarrow from an earlier fact

$$\begin{aligned}
 & \forall F \quad (*) \\
 & |H| = |\text{Gal}(K/L)| \\
 & \text{Also know: } |\text{Gal}(K/\sigma L)| \leq [K:\sigma L] = |H| \quad \leftarrow \text{from an earlier fact} \\
 & \left\{ \begin{array}{l} \sigma H \sigma^{-1} \text{ is a subgroup of } \text{Gal}(K/\sigma L) \rightarrow (*) \\ \text{but } |\text{Gal}(K/\sigma L)| \leq |\sigma H \sigma^{-1}| \rightarrow (***) \end{array} \right. \\
 & \Rightarrow \boxed{\sigma H \sigma^{-1} = \text{Gal}(K/\sigma L)} \quad \text{So the claim is proved } \checkmark
 \end{aligned}$$

So, note first that H note first that L is isomorphism τL , because σ is an automorphism homomorphism from L to σL it is injective because, any field homomorphism is injective it is surjective because it goes to σL by definition, σL is the image. So, this is isomorphic isomorphism of fields. This implies L is isomorphic to this as F vector spaces. This is isomorphism as F vector spaces but this means L colon F the degree is same as σL colon F .

So, the picture again I will go here K is here, L is here, σL is here, F is here is an isomorphism. This degree is same as this degree, but this implies of course, $K L$ is equal to K is equal to $K \sigma L$ this is a triviality, because K over F is on the one hand L colon L times L colon F , on the other hand it is K colon σL colon times σL , colon F , but L colon F is same as σL colon F .

So, $K L$ is equal to K colon σL and once this happens, this is of course, the order of K over L . So, this is order of H , because K over L is Galois. So, this is because K colon L is equal to the cardinality of the Galois group of K over L this of course, is equal to H because H is the Galois group of K over L .

So, this carnality is H , but on the other hand, we do know that this is less than or equal to, so, what do I want to say this. So, this so on the other hand, we also know so, this is something that I mentioned before the cardinality or the order of the Galois group of K over L is less than or equal to K colon σL . So, this is from an earlier fact. In fact, this was recalled in a video two,

three videos back. In general, if every time you have an extension field extension, the order of the Galois group in fact divides the degree of the extension. In fact, this divides this, so, this is true.

So, now, this is equal to order of H , because this is equal to this this is equal to this this is equal to H , this is less than or equal to H . And on the other hand order of H , so, I am all over the place I am sorry is $\sigma H \sigma^{-1}$. So, this is a general group theory fact. If you take a subgroup and conjugate of it, they both are the same cardinality.

So, this is equal to this, but this is a subgroup of this. So, I am just using two facts $\sigma H \sigma^{-1}$ inverse is a subgroup of, so, maybe I will write it here, $\sigma H \sigma^{-1}$ is a subgroup that is just this fact here, $\sigma H \sigma^{-1}$ is a subgroup. Remember, if H is a subgroup $\sigma H \sigma^{-1}$ is also a subgroup of G .

In fact, it is contained in Galois K over σL is what we have shown this here. So, it is a subgroup of this, but, the order of the bigger group is less than order of the smaller group. So, this is star star, so, that that is proved here and this is star and that is proved here. So, star star says that, order of the potentially smaller group thing is bigger than the order of the bigger group.

So, these two together imply $\sigma H \sigma^{-1}$ is Galois K over L as required so, the claim is proved sorry, this is Galois so, the claim is proved. So, the claim was $\sigma H \sigma^{-1}$ is the Galois group of K over σL . So, if the Galois group of this is H , this is $\sigma H \sigma^{-1}$, so, we are almost done there done with this proof. The crucial statement we have just proved.

So, if the Galois group of K over L is H , the Galois group of this which is also, remember a Galois extension always, because, if K over F is Galois and σL is an intermediate field K over σL is also Galois. So, this is the Galois group of this. So, σL that σ also determines the Galois group here. So, that is the statement, which we have just proved. So, hopefully this proof is clear to you. If not please stop the video and just go back and go through this, this is a simple argument maybe I sort of made it more complicated than it should be.

(Refer Slide Time: 14:48)

Suppose L/F is Galois: Then $\sigma L = L \forall \sigma \in G$

$\sigma: K \rightarrow K$
 L/F Galois $\Rightarrow L/F$ normal
 So $\sigma: L \rightarrow K$ has image in L
 $\Rightarrow \sigma(L) \subseteq L$
 inverse $\Rightarrow \sigma(L) = L$

$H = \text{Gal}(K/L) = \text{Gal}(K/F_L)$
 $\sigma H \sigma^{-1} \forall \sigma \in G$
 $\therefore H = \sigma H \sigma^{-1} \forall \sigma \in G$
 $\Rightarrow H$ is normal in G ✓

Diagram:
 K
 $\swarrow \sigma H \sigma^{-1}$
 $L \xrightarrow{\sigma} \sigma L$
 \searrow
 F

Suppose that H is normal in G : Then $\sigma H \sigma^{-1} = H \forall \sigma \in G$

$\Rightarrow \text{Gal}(K/\sigma L) = \text{Gal}(K/L) \forall \sigma \in G$
 $\Rightarrow \text{Gal}(K/\sigma L) = \text{Gal}(K/L) \forall \sigma \in G$
 $\Rightarrow K = K$
 $\Rightarrow \sigma L = L \forall \sigma \in G$

K/L are Galois \Rightarrow

$$\begin{array}{l}
 \Rightarrow K = \dots \\
 K/L \text{ is Galois} \Rightarrow \sigma L = L \quad \forall \sigma \in G \\
 \text{Hence, restricting } \sigma \text{ to } L \text{ we get a homomorphism of groups as follows:} \\
 \sigma: K \rightarrow K \\
 \sigma|_L: L \rightarrow L \\
 G = \text{Gal}(K/L) \rightarrow \text{Gal}(L/F) \\
 \sigma \mapsto \sigma|_L \quad \left[\text{check that this is a group homom} \right]
 \end{array}$$

Now, we are ready to prove the second part. So suppose, L is normal in L is Galois over F so let me write it like this, suppose L over F is Galois we want to show that Galois K over L is normal in G . So, suppose L is normal in F that means, so, this is an observation that we made in the past. Because σ is an automorphism from K to K , if you restrict σ to L , it σ is, so the reason is L over F is Galois implies L over F is normal.

So, the map from L to K has image in L , has image in L that means, sorry, so as image in L and hence, σL is in L , but because of an exercise we did, so this is an exercise, every time you have a algebraic extension L over F and you have an F auto F homomorphism from L to L , the image is always equal to L .

So, this implies that σL equals L . But this means, so in the picture that I had earlier which I will write here $K L \sigma L F$, so if the Galois group here is H Galois group here is $\sigma H \sigma$ inverse. So, if these are actually equal, then Galois of K over L is equal to Galois K over σL because they are the same fields.

So, the fixed Galois groups are also equal, but this is σH , this is H this is $\sigma H \sigma$ inverse, this is true for all σ in G . So, H equals $\sigma H \sigma$ inverse for all σ in G which is precisely the definition of normal subgroup. So, the one direction is proved. So, if so, let me just go back to the statement of the theorem and intermediate field is Galois if and only if

Galois K over L is normal in Galois K over F . So, assuming it is normal we have shown that its corresponding subgroup is normal.

So, now, suppose that H is normal in G , we are going to show that L is Galois over F , why is this? Suppose H is normal in G , then by definition of normality $\sigma H \sigma^{-1} = H$ for all σ in G , this implies $\text{Galois } K \text{ over } \sigma L$ is equal to $\text{Galois } K \text{ over } L$ for all σ in G , because $\sigma H \sigma^{-1} = H$ is equal to $\text{Galois } K \text{ over } L$. So, $\text{Galois } K \text{ over } L$ is equal to $\text{Galois } K \text{ over } \sigma L$ for all σ in G , but that means, by applying K power these are two groups.

So, this is straightforward if you have two groups, their fixed fields are equal. So, $K^{\text{Galois } K \text{ over } L} = K^{\text{Galois } K \text{ over } \sigma L}$, but this is because of the various facts that we have done in the past and recall several times is exactly σL , $K^{\text{Galois } K \text{ over } \sigma L} = L$, $K^{\text{Galois } K \text{ over } L} = L$, this is of course, because $K \text{ over } \sigma L$ and $K \text{ over } L$ are Galois that is required for this implication.

So, σL is equal to L for all σ in G . So, σL is equal to L , this basically proves that it is normal almost, but we want to do this in a way that gives the last statement about the Galois group of F over L in one shot, so, let us do the following. So, hence restricting σ to L , we get a homomorphism of groups. And in any problem session some time ago I did talk about this restriction map.

So, G which is $\text{Galois } K \text{ over } L$ to $\text{Galois } L \text{ over } F$, σ goes to σ restricted to L that is the restriction map. So, σ is a function from K to K . So in general, if you restrict to L , you only go to σL , but I have just shown using the H is normal, I have shown this L . So, it is in fact an automorphism of L . So, σ going to σL does map to $\text{Galois } L \text{ over } F$. Remember σ a priori is a $(\text{Galois } K \text{ over } L)$ automorphism.

So, it will fix F pointwise. So this is a group homomorphism, which is a trivial statement, check that this is a group homomorphism. There is really nothing to show here. Because σ composed with σ^{-1} restricted to L is $\sigma \sigma^{-1}$ restricted to L composed with $\sigma \sigma^{-1}$ restricted to L that is all. Because σ restricted to L is just σ is just that you are only applying it to elements of L . So this is a trivial exercise.

(Refer Slide Time: 21:07)

What is the kernel of φ ? $\left\{ \begin{aligned} \text{Ker } \varphi &= \{ \sigma \in G \mid \sigma|_L = \text{id} \} \\ &= \{ \sigma : K \rightarrow K \mid \sigma|_L = \text{id} \} \\ &= \text{Gal}(K/L) = H \end{aligned} \right.$

H is normal in G

\therefore We have an injective map $G/H \hookrightarrow \text{Gal}(L/F)$

$\begin{array}{c} K \\ | \\ L = K^H \\ | \\ F \end{array}$ $[L:F] = [K^H:F] = |G/H|$

(*) of Theorem

H is normal in G

\therefore We have an injective map $G/H \hookrightarrow \text{Gal}(L/F)$

$\begin{array}{c} K \\ | \\ L = K^H \\ | \\ F \end{array}$ $[L:F] = [K^H:F] = |G/H| \leq |\text{Gal}(L/F)| \leq [L:F]$

(*) (*)

by an earlier fact

Hence $[L:F] = |\text{Gal}(L/F)| \Rightarrow L/F$ is Galois

Moreover $(*) (*)$ is an isomorphism: $|G/H| = |\text{Gal}(L/F)| \checkmark$

$\frac{1}{F}$ Hence $[L:F] = |\text{Gal}(L/F)| \Rightarrow L/F$ is Galois.
 Moreover (ϕ, ψ) is an isomorphism: $|G/H| = |\text{Gal}(L/F)| \checkmark$
 Hence $G/\text{Gal}(K/L) \cong \text{Gal}(L/F)$
 This completes the proof of (2) and the theorem. \square

Suppose that H is normal in G : Then $\sigma H \sigma^{-1} = H \quad \forall \sigma \in G$
 $\Rightarrow \text{Gal}(K/\sigma L) = \text{Gal}(K/L) \quad \forall \sigma \in G$
 $\Rightarrow K^{\text{Gal}(K/\sigma L)} = K^{\text{Gal}(K/L)} \quad \forall \sigma \in G$
 $\Rightarrow K^{\text{Gal}(K/L)} = K$
 $\Rightarrow \sigma L = L \quad \forall \sigma \in G$
 Hence, restricting σ to L we get a homomorphism of groups as follows:
 $\sigma: K \rightarrow K$
 $\sigma|_L: L \rightarrow \sigma L = L$
 $G = \text{Gal}(K/L) \xrightarrow{\varphi} \text{Gal}(L/F)$
 $\sigma \mapsto \sigma|_L$
 [check that this is a group homomorphism \checkmark]

$\varphi: G \rightarrow \text{Gal}(L/F)$ Ker $\varphi = \{ \sigma \in G \mid \sigma|_L = \text{id} \}$

1.3 There is exactly ...
 $F = \mathbb{Q}$ 2 intermediate fields, namely $F \neq K$.

(2) Let L be an intermediate field of the extension K/F .
 $H := \text{Gal}(K/L) \leq G := \text{Gal}(K/F)$

Claim: Let $\sigma \in G$. Then $\text{Gal}(K/\sigma L) = \sigma H \sigma^{-1}$.

pf: Let $\tau \in \text{Gal}(K/\sigma L)$. Then $\tau \sigma^{-1} \in H$, so $\tau = \sigma \tau \sigma^{-1} \in \sigma H \sigma^{-1}$.
 Conversely, let $\tau \in \sigma H \sigma^{-1}$. Then $\tau \sigma^{-1} \in H$, so $\tau \sigma^{-1} \in \text{Gal}(K/L)$. Thus $\tau \sigma^{-1} \in H$, so $\tau \in \sigma H \sigma^{-1}$.

Note that $\sigma L \subseteq K$ because $\sigma: K \rightarrow K$ is an auto of K .
 $\sigma L = \{\sigma \alpha \mid \alpha \in L\}$

Let $T \in H, \sigma \alpha \in \sigma L$

$\{ \text{Subgroups of } G \} \xleftrightarrow{\text{bijection}} \{ \text{intermediate fields} \}$

given by $H \mapsto K^H$
 $\text{Gal}(K/L) \longleftarrow L$

Moreover, this correspondence satisfies:
 $|H| = [K : K^H]$ and $[G : H] = [K^H : F]$

(2) An intermediate field L is Galois over $F \iff \text{Gal}(L/L)$ is a normal subgroup of G . In this case, we have
 $\text{Gal}(L/F) \cong G / \text{Gal}(K/L)$

Now, what is the kernel of this? Let us say that, what is the kernel of ϕ ? I claim that kernel of ϕ consists of all homomorphism's it is I am not claiming this is the truth. Such that σ is identity. So, that means σ is an automorphism from K to K such that $\sigma|_L$ is identity, but this is precisely $\text{Gal}(K/L)$.

So, $\text{Gal}(K/L)$ is H of course, H is $\text{Gal}(K/L)$ as I should keep reminding you. So, that we fixed at the beginning, L is Galois over F if and only if H is a normal subgroup of G . So, then what we have is H is the kernel of this map that I just defined. Because if something is in the kernel H , then clearly $\sigma|_L$ is identity, if something is in the kernel σ will be in K . So this is trivial.

So, that means we have an inclusion and note that H is normal in G that is hypothesis. So, we have an inclusion or rather to be precise, and injective map, $G \text{ mod } H$ to $\text{Galois } L \text{ over } F$. Let us, stare at this and see what we get. So, we have an injective map because this is an isomorphism theorem of groups. You have a map from one group to another, if you go mod (\cdot) (22:43) the kernel, it becomes an injective map.

So now, let us just play with this. So, K, L, F of course, that is what we have and L is the intermediate field that we started with. So, $L \text{ colon } F, L \text{ is } K \text{ power } H, L \text{ colon } F \text{ is } KH \text{ colon } F$ this is by the equality of L and KH , this is the order of $G \text{ mod } H$, this is the statement by part one of the theorem.

The theorem that we are now proving the main theorem because if you go back to the statement of the theorem, $K \text{ colon } K \text{ power } H \text{ is } H$ but $K \text{ colon } H \text{ power } F \text{ is } G \text{ colon } H$, which is order of $G \text{ mod } H$ because H is a normal subgroup I can talk about $G \text{ mod } H$. So, $G \text{ mod } H$ is this, but then this is less than or equal to because of this inclusion the order of $L \text{ over } F$, that is because of this.

Because $G \text{ mod } H$ is a subgroup of this, so this subgroup will have smaller order than the bigger group. So, the order of $G \text{ mod } H$ is less than or equal to order of $\text{Galois group of } L \text{ over } F$, but then by another application of something that we know, order the $\text{Galois group of any extension in general}$ is less than the degree of the extension, this by an earlier fact.

We know very well that cardinality of the Galois group is at most the order of degree of the extension and that is inequality if and only if the extension is Galois . So, now we have $L \text{ colon } F$ on the left hand side $L \text{ colon } F$ on the right hand side. So, everything in the middle is equal. So, hence in particular $L \text{ colon } F \text{ is } \text{Galois } L \text{ over } F$. This already implies that $L \text{ over } F$ is Galois as required.

Remember, this is an equivalent condition for Galois extensions that I recall in a previous video. So, if the extension degree is equal to the order of the Galois group , the extension is Galois , but moreover, the star here, how this map triple star that we have here is an injective map. Moreover, triple star is an isomorphism.

Because order of the group $G \bmod H$ is equal to the those are some other things that we pair here $G \bmod H$ $G \bmod H$ is here Galois L over F , if is this this an inequality. So, this is an isomorphism. So, you have an injective map of finite groups, which have the same order then that must be an isomorphism inclusion map. So, these are finite groups, so, that must be an isomorphism.

So, this is also going to prove the. So, this completes the proof of we got the final statement also, final statement told us that if you do have an fact that L is Galois over F Galois L over F is isomorphic to $G \bmod \text{Galois } K \text{ over } L$ which is exactly what we have. So, so maybe before I write that, I will simply say hence, $G \bmod H$, which is I have written that somewhere here Galois K over L is isomorphic to Galois over F . This is exactly the last statement of the theorem.

So, this completes the proof of 2 and the theorem. So, let me stop the video here. And what we want to do in the next videos is to apply this main theorem. So, we will spend one video or two videos giving you some nice applications of this and then we will go back to the most serious applications, which involve showing the insolubility of quintics by radicals and studying some other special kinds of Galois extensions.

(Refer Slide Time: 27:43)

Diagram illustrating the Galois correspondence:

$$\begin{array}{ccc}
 \{ \text{Subgroups of } G \} & \xleftrightarrow{\text{bijection}} & \{ \text{Intermediate fields} \} \\
 \text{given by } H \mapsto K^H & & H_1 \supseteq H_2 \Rightarrow K^{H_1} \subseteq K^{H_2} \\
 \text{Gal}(K/L) \longleftarrow L & & \text{Gal}(K^{H_1}/K^{H_2}) \subseteq \text{Gal}(K^{H_2}/K^{H_1}) \Leftrightarrow L_1 \supseteq L_2
 \end{array}$$

Moreover, this correspondence satisfies:

$$|H| = [K : K^H] \quad \text{and} \quad [G : H] = [K^H : F]$$

(2) An intermediate field L is Galois over $F \Leftrightarrow \text{Gal}(L/F)$ is a normal subgroup of G . In this case, we have

$$\text{Gal}(L/F) \cong G / \text{Gal}(K/L)$$

So, in this video, I completed the proofs of the main theorem of Galois theory, which says that if you have a Galois extension, there is a bijection between the subgroups of the group and

intermediate fields of the extension and moreover, if you are given an intermediate field, that is Galois over the base field if and only if the corresponding sub group is a normal subgroup of the Galois group of the original extension.

And if that is the case, we also do know how to find the Galois group of the extension L over F using the Galois group of the original extension and the Galois group of the top extension. So, let me stop this video here, and we will continue with applications in the next video. Thank you.
