**Chennai Mathematical Institute**  
**Lecture 27**  
**Problem Session Part 5**

Welcome back. In the last few video we proved the main theory of Galois Theory and we learned, for example, how to prove fundamental theorem of algebra using the main theorem of Galois Theory. So, in this video and one or two videos after this, we are going to do some problems.

(Refer Slide Time: 00:32)

Problems: (1) Let  $K/F$  be an extension of finite fields. Then  $K/F$  is Galois and the Galois group  $\text{Gal}(K/F)$  is cyclic.

Def: A finite extension  $K/F$  is called "cyclic" if  $K/F$  is Galois and  $\text{Gal}(K/F)$  is cyclic.

{ Eg:  $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$  is cyclic;  $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$  is not cyclic (not Galois),  
 $\mathbb{Q}(\omega, \sqrt[3]{2})/\mathbb{Q}$  is not cyclic.

Any ext of finite fields is cyclic.

Any ext of finite fields is cyclic.

Soln: Say char  $K = p$   
" " " " char  $F$

Main thm:  $K/F$  is Galois  
and  $\text{Gal}(K/F) \leq \text{Gal}(K/\mathbb{F}_p)$   
cyclic  $\leq$  cyclic

We know:  $K/\mathbb{F}_p$  is Galois  
and  $\text{Gal}(K/\mathbb{F}_p)$  is a cyclic gp.  
So  $K/\mathbb{F}_p$  is a cyclic ext.  
(Recall: the Frobenius map generates the Galois ext.)

So, before we proceed further and see more applications of main theorem, it is good to learn how to apply so far, whatever we learned so far and solve some exercise. So, let me start with some observations that I made in the past but I want to record them concretely so that you have a record of them and we discuss all the missing details. So, first problem is, let  $K$  over  $F$  be an extension of finite fields.

So, then  $K$  over  $F$  is Galois that is the first statement and moreover the Galois group  $K$  over  $F$  is cyclic, so let me give you a definition here before we proceed with the solution. A finite extension, just a word about the terminology, finite extension always refers to an extension of fields that is a finite extension. Here I am not going to say finite extension, I am not asserting anything whether  $K$  and  $F$  are finite fields, that is a general statement.

Here I am saying  $K$  over  $F$  is an extension of finite fields that means  $K$  and  $F$  are finite fields. So, there is a big difference between this. So, a finite extension of  $K$  over  $F$  is called cyclic, if  $K$  over  $F$  is Galois so it has to be Galois first and the Galois group is cyclic. So, cyclic extension is a short form for a Galois extension, whose Galois group is cyclic. So, examples of such things are,  $\mathbb{Q}(\sqrt[2]{2})$  over  $\mathbb{Q}$  is cyclic. Because it is Galois, its Galois group is  $\mathbb{Z}$  not  $2\mathbb{Z}$ . On the other hand,  $\mathbb{Q}(\sqrt[4]{2})$  over  $\mathbb{Q}$  is not cyclic.

This is because it is not a Galois. It is not a Galois extension so it cannot be cyclic, only after you determine it is a Galois extension, you ask for its Galois group. On the other hand, if you take  $\mathbb{Q}(\omega, \sqrt[3]{2})$  over  $\mathbb{Q}$ , this is Galois but the Galois group is  $S_3$ , so it is not cyclic. So, the assertion of this problem is, any extension of finite fields is cyclic. So, that is what the problem is asking you to show.

So, if you have 2 finite fields, one containing the other, it is a Galois extension and its Galois group is cyclic. In other words, it is a cyclic extension. Let me prove this, something which we have done before. Let us say characteristic of  $K$  is  $P$ , so this is of course will be the characteristic of  $F$  also, if you feel the extension, both will be of same characteristic. So, you have  $K$  or  $F$ , but this both live over the prime field.

So, we know, so this I will assert without proof,  $K$  over  $\mathbb{F}_P$  is Galois and Galois group of  $K$  over  $\mathbb{F}_P$  is isomorphic to  $\mathbb{Z}$  over  $\mathbb{R}$ ... sorry, it is cyclic group, let me simply say that is a cyclic group. So,  $K$  over  $\mathbb{F}_P$  is a cyclic extension. So, this is Galois and that is because, recall that, the Frobenius Map generates the Galois group.

In proving this, in fact, we also proved that it is Galois extension because the Frobenius Map will have the right order so that order is the degree of the field extension. Now by the main theorem, this is not main theorem, I mean  $K$  over  $F$  Galois is actually not the main theorem. That is just the standard fact about Galois extension because they are supposed to be normal separable. So, this is Galois, what the main theorem says, is that Galois  $K$  over  $F$ ...

This is even not the main statement of the main theorem but I am putting every statement of the Galois groups and sub groups under the heading of the main theorem. So, it implies that, this is sub group, but this is cyclic so this implies this is cyclic. The sub group of a cyclic group is cyclic, so we are done. So, this  $K$  over  $F$  is a cyclic extension so  $K$  over  $F$  is a cyclic extension. So, that is the solution for the first problem.

(Refer Slide Time: 5:54)

(2) Show that a normal extension need not be Galois.

Sol.  $F = \mathbb{F}_p(t)$  (where  $p$  is prime and  $t$  is a variable)

consider  $f(x) \in F[x]$  given by  $f(x) = x^p - t$

Claim:  $f$  is irreducible over  $F$ .

Pf: let  $K = \text{Sp fld of } f \text{ over } F$ .

Then  $f$  has only one root in  $K$ .  
 root of  $f$ . So  $\alpha^p = t$ . How does  $f$  factor in  $K[X]$ ? We have  $f(x) = (x - \alpha)^p$  unique factor of  $f$  in  $K[X]$ .  
 Since  $\text{char} = p$ :  $(x - \alpha)^p = x^p - \alpha^p = x^p - t = f(x)$   
 This also gives that  $f$  is irr over  $F$ . *(This is an exercise for you)*

Since  $\text{char} = p$ :  
 This also gives that  $f$  is irr over  $F$ . *(This is an exercise for you)*  
Conclusion:  $K/F$  is normal because  $K$  is the sp. fd of  $x^p - t$ ;  
 $K/F$  is not separable because  $\alpha$  is not separable over  $F$ ;  
 the irr poly of  $\alpha$  over  $F$  is  $x^p - t = f(x)$ . And  $f(x)$  doesn't have distinct roots in  $K$ .

So, this one is the first problem and now the second problem is not new to you, I will sort of mention them before but I wanted to explicitly talk about them once more. So, show that a normal extension need not be Galois, so remember Galois equals normal plus separable, always finite. All extensions are finite for me, so finite extension is Galois if and all if it is normal and separable. But the point is, it is not enough that it is nearly normal. In characteristic zero, of course it is enough but not in general.

So, the argument here is, you take  $F_p[t]$  where  $p$  is the prime number of course, and  $t$  is the variable. So, this is the field of rational functions in one variable over  $F_p$ . And let us consider the polynomial,  $f$  of  $X$  in  $F[X]$  given by... I think, I have did  $p$  equal to 2 case but more generally one can do this. Take  $X^p - t$ . So, first claim is that,  $f$  is irreducible over  $F$ . So, for  $p$  equal to 2, all you need to argue is that, it has no roots.

But for higher values of  $P$ , it is not enough to argue that it has not roots. But one can argue that, it is not separable and it has only one root. So, actually what we will show is that, so let us take the fixed field, the splitting field. Let me remind you  $F_p t$ , let us take the splitting field of  $f$  over  $t$ . Then,  $f$  has only one root in  $K$  so the reason is, so let  $\alpha$  be root of  $f$  in  $K$ . Because  $K$  is the splitting field, it will...  $f$  will have a root so we will pick one of them called  $\alpha$ . So, we have  $\alpha^p = t$ .

So, now I claim that, there cannot be any other root. So, let us take the polynomial  $x^p - \alpha^p$ , so how does  $f$  factor in  $K$ ,  $x^p - \alpha^p$ ? So, that is what I am saying, that is what I wanted to understand. So, I claim that, we have  $f(x) = x^p - \alpha^p$ , so this is because  $x^p - \alpha^p$ , since characteristic is  $p$ ,  $x^p - \alpha^p$  will be  $(x - \alpha)^p$ . All the mixed terms will go away.

So, this will be  $(x - \alpha)^p$ ,  $\alpha^p = t$ , right? So, this is true and in a polynomial ring over a field, factorisation is unique so this also affects. So, this must be the unique factorisation of  $f$  in  $K[x]$ , factorisation is not available in  $F[x]$ , so this is only available in  $K[x]$ . So, this proves you in one short that  $f$  is not separable and also it is irreducible. So, note that, this also gives that  $f$  is irreducible over  $F$ .

So, this is because if it is not.. it will have a factor and those factors must involve  $x - \alpha$ . So, actually, this requires a little bit approve, so I am going to leave this as an exercise for you. And I want to get back to the main part of the problem which of course, is to show that  $K$  over  $F$  is not Galois. For that I do not need  $F$  to be splitting field. So,  $F$  to be irreducible. This claim is in fact, an exercise. I want to do other problems, so I will skip this.

So, I want to say that  $F$  is irreducible and it is an exercise for you that is irrelevant to the problem that I am trying to consider. So, now because of this, what is the conclusion of everything that we have done so far?  $K$  over  $F$  is normal because  $K$  is a splitting field of  $x^p - t$ . And  $K$  over  $F$  is not separable because  $\alpha$  is not separable over  $F$ .

So, this is because irreducible polynomial of  $\alpha$  over  $F$  is  $x^p - t$  or  $F$  rather by reclaim is,  $x^p - t$ . At this, technically without proving the claim, all you can say is that, irreducible polynomial is the device of this. But once you prove the claim, you can show that, this is the irreducible polynomial and this of course I call  $f(x)$  and  $f(x)$  does not have distinct roots in  $K$ . So, it is not separable because it does not have distinct roots.

And you can actually make do without this claim because all you need to know is that, the polynomial has no roots in  $K$  and no roots in  $F$  which of course is true statement because there cannot be rational function whose  $p$ th power is  $t$ . So, that we have viewed before when we talked about this in the previous video.

So, this has no roots so the irreducible polynomial will be at least degree 2 and only root of this is  $\alpha$  so it does not have distinct roots. The number of roots is strictly less than the degree so it does not have distinct roots, irreducible polynomial does not have distinct roots even if irreducible polynomial is not this, and it is a factor of this with degree at least 2. So, it does not have roots and hence it is not separable so  $K$  over  $F$  is not Galois.

(Refer slide Time: 14:12)

Alternately: there exists only one  $F$ -auto of  $K$ .  
 Any  $F$ -auto  $\sigma: K \rightarrow K$  must send  $\alpha$  to  $\alpha$ .  
 $\therefore |\text{Gal}(K/F)| = 1 < [K:F] = p$   
 (equality follows from the claim)  
 Even without the claim, we know  $[K:F] \geq 2$  since  $X^p - t$  has no roots in  $F$ .

consider  $f(x) \in F[x]$  given by  $f(x) = X^p - t$   
claim:  $f$  is irreducible over  $F$ . Exercise  
 Pf: Let  $K = \text{Sp fld of } f \text{ over } F = \mathbb{F}_p(t)$   
 Then  $f$  has only one root in  $K$ : let  $\alpha \in K$  be a root of  $f$ . So  $\alpha^p = t$ . How does  $f$  factor in  $K[x]$ ? We have  $f(x) = (x - \alpha)^p$  (unique fac of  $f$  in  $K[x]$ )  
 Since  $\text{char} = p$ :  $(x - \alpha)^p = x^p - \alpha^p = x^p - t = f(x)$   
 $\therefore$  since that  $f$  is irr over  $F$ . This is an exercise for you

*claim is easy to prove when  $p=2$*

NPTEL

$x^p - t$  has no roots in  $F$

(3) Suppose  $F$  is a field and  $\text{char}(F) \neq 2$ . Let  $K/F$  be a deg 2 ext.  
 Then  $K/F$  is Galois and  $K = F(\alpha)$  where  $\alpha^2 \in F$ .  
 ( $K$  can be obtained by adding a square root of an element of  $F$ )

Soln: Let  $\alpha \in K \setminus F$ . Then  $K = F(\alpha)$ .

Soln: Let  $\alpha \in K \setminus F$ . Then  $K = F(\alpha)$ . Since  $[K:F] = 2$ ,  
 $\deg$  of  $f(x) = 2$  where  $f(x) \in F[x]$  is the irr poly of  $\alpha$   
 over  $F$ . Say  $f(x) = x^2 + bx + c$ ,  $b, c \in F$ .  
 Roots:  $\frac{-b \pm \sqrt{b^2 - 4c}}{2}$  (Here is where  $\text{char}(F) \neq 2$  hypothesis is used)

So, you can also see this by... alternatively you can show non-Galois by there exists only 1  $F$  automorphism of  $K$ . because any automorphism that fixes  $F$ ... any  $F$  automorphism must send  $\alpha$  to  $\alpha$  because  $\alpha$  is the only root of the irreducible polynomial of  $\alpha$ . So, any automorphism must send  $\alpha$  to  $\alpha$  so that the order of the Galois group is 1 which is strictly less than the degree is  $p$ .

So, again the equality here follows from the claim which I have not proved but even if you do not agree that  $x^p - t$  is irreducible, what you can definitely say is that,  $K : F$  is at least 2 even without the claim. We know,  $K : F$  is at least 2. So, suddenly we get a contradiction because we get non-Galois because 1 is strictly less than 2. Since  $x^p - t$  has no roots in  $F$ . So, this has no roots in  $F$  so this is at least 2 so the cardinality of the Galois group is strictly less than the degree and hence it is not Galois.

And finally before I move on to the next problem, let me remark finally that, the claim is easy to prove when  $p$  equals 2. This is the degree to polynomial and degree to polynomial is irreducible if and only it has no roots. So, it has no roots is an easy statement. And that is enough to conclude irreducibility in  $p$  equal to 2.

So, you do have a normal extension that is not Galois by taking characteristic to... but in general you can also do this and without proving the claim also we have shown that it is a normal extension and it is not a Galois extension. But it is still nice to prove the claim and complete the picture and conclude that this is an equality, the degree is actually  $p$ . That I will leave for you to do.

So, now let me continue and do some more examples, so your next problem... let us see what I want to do next. Yeah, so let us see the following problem, this also is something which came up before but I am trying to tie loose hands here and settle this. This is a nice statement and this is something we will see more generally later. Suppose  $F$  is a field and characteristic of  $F$  is not 2.

So,  $F$  is any field, all we are assuming is that, its characteristic is different from 2. Let  $K$  over  $F$  be degree 2 extension, then  $K$  over  $F$  is Galois and  $K$  is in fact, equal to  $F(\alpha)$  where  $\alpha^2$  is in  $F$ . So, in words what we basically say is that,  $K$  can be obtained by adding a square root. So, you take  $\alpha^2$  that is in  $F$  so you add a square root of that to get  $\alpha$  so  $K$  equal to  $F(\alpha)$  so this is a nice structured result for degree 2 extensions of fields which are not characteristic 2.

So, the proof is very simple here, so what we know is that degree is 2, so we can assume that, the recent element... not assume, we do know that there is an element that we can take whose... Let us say,  $\beta$ .. no, let us say  $\alpha$  is in  $K$  minus  $F$  so that we know it exists because  $K$  is different from  $F$  so then, we do not quite know that  $\alpha$  will do the job for us because  $\alpha^2$  may not be in  $F$  so we do not know yet that this particular  $\alpha$  will do.

So, what we do now is, to exhibit some other element which does the job. So, since  $K:F$  is 2, there exists.... The degree of  $f_x$  is 2 where capital  $F(x)$  is the irreducible polynomial of  $\alpha$  over capital  $F$ . Remember,  $K$  equal to  $F(\alpha)$ , so this implies degree of  $\alpha$  over  $F$  is 2. That means its irreducible polynomial is 2 so let us write down what it is. Say,  $f_x$  equals  $x^2$  plus  $bx$  plus  $c$  where  $b$  and  $c$  are elements of the base field.

So,  $x^2 + bx + c$ , now what are the roots, roots of this because of the quadratic formula which we have recalled earlier? These are the roots and here is where the characteristic different from 2 hypothesis is used because you cannot divide by 2 if the characteristic is 2, so roots are given by this is a statement that only holds in characteristic different from 2 so the roots are this.

(Refer Slide Time: 21:00)

over  $F$ . Say  $\dots$   
 roots:  $\frac{-b \pm \sqrt{b^2 - 4c}}{2}$  (Here is where  $\text{char}(F) \neq 2$  hypothesis is used)  
 $\alpha = \frac{-b + \sqrt{b^2 - 4c}}{2} \in K$   
 $\alpha = \frac{-b - \sqrt{b^2 - 4c}}{2} \in K$   
 Roots of  $f$  are  $\frac{-b + \sqrt{b^2 - 4c}}{2}, \frac{-b - \sqrt{b^2 - 4c}}{2}$

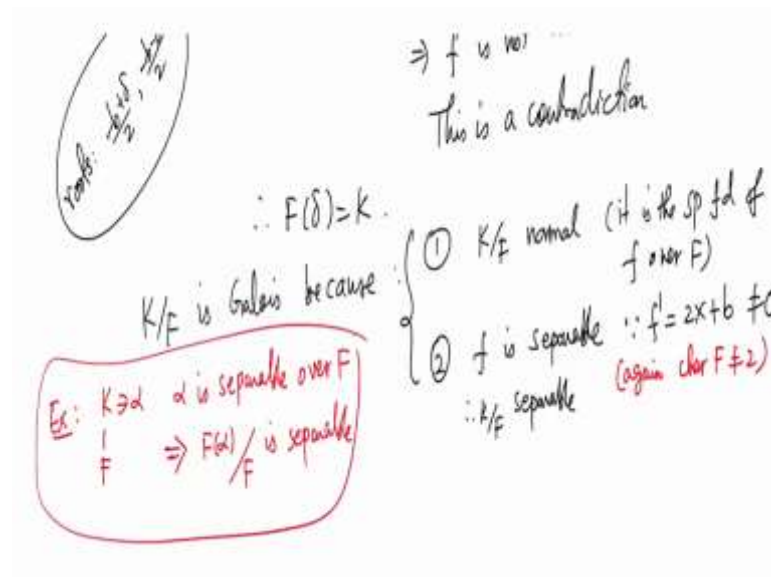

---

Let  $\delta = \sqrt{b^2 - 4c}$  ("discriminant of  $f(x)$ ")  $\boxed{\delta \in K}$   
Claim:  $K = F(\delta)$  and  $\delta^2 \in F$ .  
 Pf:  $\delta^2 = b^2 - 4c \in F$  ✓  $\begin{pmatrix} K \\ F(\delta) \\ F \end{pmatrix} \Rightarrow F(\delta) = K \text{ or } F(\delta) = F$

Claim:  $K = F(\delta)$  now...  
 Pf:  $\delta^2 = b^2 - 4c \in F$  ✓  $\begin{pmatrix} K \\ F(\delta) \\ F \end{pmatrix} \Rightarrow F(\delta) = K \text{ or } F(\delta) = F$

$F(\delta) = F \Rightarrow \delta \in F \Rightarrow f$  has roots in  $F$   
 $\Rightarrow f$  is not irr over  $F$ .  
 This is a contradiction.

$\therefore F(\delta) = K$ .  
 $K/F$  is Galois because: ①  $K/F$  normal (it is the sp. fld. of  $f$  over  $F$ )

Now let us take delta to be square root  $b^2 - 4c$  so this is called the discriminant, if you are familiar with this terminology, but that is irrelevant. So, let us take this, delta to be this. So, I claim that,  $K$  is  $F(\delta)$  and  $\delta^2$  is in  $F$ . So, this proves the part about  $K$  being generated by  $\sqrt{x}$  of an element in  $F$ . So, clearly  $\delta^2$  is  $b^2 - 4c$  is in  $F$ , this is okay. But why is  $K$  equal to  $F(\delta)$ ?

This is also clear because  $K$  is here,  $F(\delta)$  is of course here because  $\delta$  is in  $K$  because the roots are in  $K$ . So,  $\alpha$  is  $\frac{-b \pm \sqrt{b^2 - 4c}}{2}$  or  $\alpha$  is  $\frac{-b \pm \sqrt{b^2 - 4c}}{2}$ . So,  $\alpha$  is a root, if once  $\alpha$  is in  $K$ , you can clearly rearrange terms to conclude that  $\sqrt{b^2 - 4c}$  is in  $K$ . So,  $F(\delta)$  is sub field of  $K$  and this is a degree to extension.

So, this implies  $F(\delta)$  is either  $K$  or  $F(\delta)$  is equal to  $F$ . So, if  $F(\delta)$  is  $K$ , is the statement, if  $F(\delta)$  is equal to  $F$  this implies  $\delta$  is in  $F$ . But that means,  $F$  has roots in  $F$  because if this  $\delta$  is in  $F$ ,  $-b$  is of course in  $F$ . So, this whole term is in  $F$  after dividing by 2 is still in  $F$ , similarly this is in  $F$ . So, this means,  $F$  is not irreducible in  $F$ . So, this is a contradiction.

Because  $F$  is irreducible polynomial of  $\alpha$  so that means  $F(\delta)$  must be in  $K$ . So, that was this, and finally the Galois  $F$  is also clear because  $K$  over  $F$  is Galois because of 2 things,  $K$  over  $F$  is normal, normal because it is a splitting field, right? Because the roots of  $F$  are this,  $\frac{-b \pm \sqrt{b^2 - 4c}}{2}$ ,  $\frac{-b \pm \sqrt{b^2 - 4c}}{2}$ ,  $\frac{-b \pm \sqrt{b^2 - 4c}}{2}$ . So, the point is if this is  $\alpha$  and  $\alpha$  is in  $K$ , this means this is also in  $K$ .

So, this is a simple observation because  $b^2 - 4ac$  is in  $K$  so basically the roots are  $\frac{-b \pm \sqrt{b^2 - 4ac}}{2}$ ,  $\frac{-b - \sqrt{b^2 - 4ac}}{2}$ . If  $\sqrt{b^2 - 4ac}$  is there, then both are there. So, this is the splitting field, and  $F$  is separable because its derivative is... so, this is non-zero so we know that non-separable irreducible polynomial must have derivative zero. So, here again characteristic  $p$  not equal to 2 is used.

So, it is separable one can argue that, if  $\alpha$  is separable, if  $F(\alpha)$  is separable then  $F$  is separable. So, that is the general statement. So,  $F$  is normal and separable so there is a small little statement here. So, this is an exercise which is really an exercise about, if  $\alpha$  is separable over  $F$ , implies  $F(\alpha)$  is separable so all polynomials in  $\alpha$  will continue to be separable. So, this is an exercise about separable extension which I will not do for now because that is not the point of this course.

So, using that, we know that it is Galois. Any degree to extension of a non-characteristic to field is Galois, of course that is false, if you take characteristic 2 as this example, shows. So, this tells me that the third problem is solved so any degree to extension is Galois and it is obtained by adding this square root.

(Refer Slide Time: 26:58)

4) Let  $K/F$  be a Galois ext s.t.  $G := \text{Gal}(K/F) \cong S_3$   
 Then show that  $K$  is the sp. fld of an  
 irreducible cubic poly over  $F$ .  
 (S<sub>3</sub>: symmetric gp on 3 letters)  
Soln:  $G \cong S_3 \Rightarrow$  there exists a Subgp  $H$  of  $G$  of order 2  
 and  $H$  is not normal in  $G$ .

Soln:  $G \cong S_3 \Rightarrow$  there is a sub-group  $H$  of order 2 and  $H$  is not normal in  $G$ . (Property of  $S_3$ )

main theorem:  $K/F$  is NOT Galois. (Since  $H$  is not normal in  $G$ )

$F(\alpha) = K$  Since  $[K:F] = 3$ , we know  $K = F(\alpha)$  for any  $\alpha \in K \setminus F$ .

Let  $f(x) \in F[x]$  be the irr poly of  $\alpha$  over  $F$ .

Since  $[F(\alpha):F] = 3$ ,  $\deg f = 3$  ✓

Claim:  $K = \text{sp. fld of } f \text{ over } F$ . (This solves the problem)

So, let me do one of the problem before we stop and then we will continue, in the next video I will do some more problems. So, the next problem is very nice also. So, the fourth problem says, let  $K$  over  $F$  be an orbitory Galois extension with such that the Galois group, let us call that  $G$  of that extension is isomorphic to  $S_3$ . So,  $S_3$  is always symmetric group on 3 letters. So, order 6 group and  $G$  is isomorphic to that.

Then, show that  $K$  is the splitting field of an irreducible cubic polynomial capital  $F$ . So, this is a nice statement, in general every Galois extension, whose Galois group is  $S_3$ , must be the splitting field of an irreducible cubic polynomial. This is a nice statement, so let us see why this is the case. So, because  $G$  is isomorphic to  $S_3$ , the first point is, there exists a sub-group  $H$  of  $G$  of order 2 and  $H$  is not normal.

This is the feature of  $S_3$ , of course any group of order 6 will have a sub-group of order 2, for that we do not need  $S_3$ . But you need  $S_3$  to conclude that, it is not normal in  $G$  because  $S_3$  will have degree to elements. For that you take any degree to element and you take the group generated by the other. That will be a group of order 2 and it is not normal. So, this is the property of  $S_3$ , this is where  $S_3$  will be read.

So, let us call that  $H$ , so now you have  $K$ , the fixed field of this, let us call that  $K^H$  and living underneath of all that is  $F$ . So, now the main theorem of Galois Theory says, here we do need the main theorem or the full force of main theorem in this problem. What does the main theorem says, first of all it says that, degree of this extension is 2 because order of  $H$  is 2 and degree of this extension is 3 because index of  $H$  is 3, and this whole thing is degree 6.

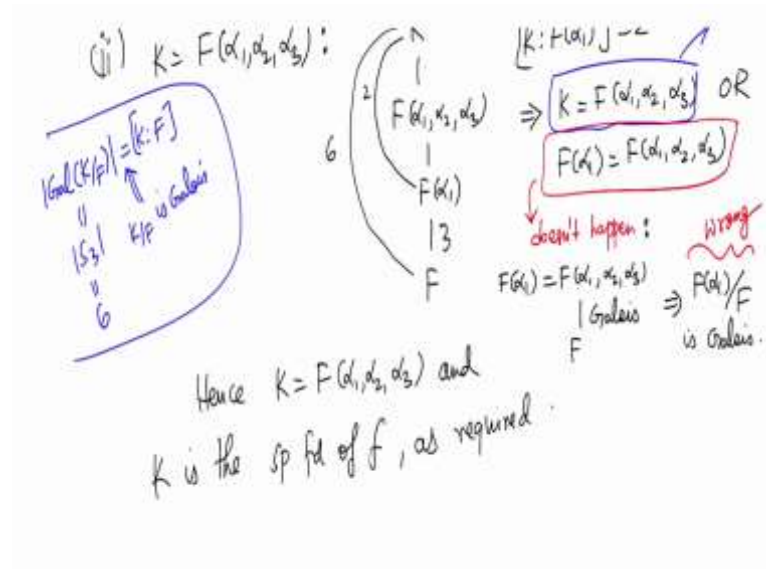

But more importantly the main theorem says that, it is not Galois. It is not Galois because it is not normal. Since,  $H$  is not normal, so it is not Galois so now... but we do know that since it is degree 3, we know  $K^{\text{power } H}$  is  $F^{\alpha}$  for any  $\alpha$  in  $KH$  not in  $F$ . So, take any  $\alpha$  because it is not equal as fields. There is an  $\alpha$  in  $KH$  that is not equal to... that is not in  $F$  so then  $F^{\alpha}$  is an intermediate field, it cannot be equal to  $F$  but this is a prime degree extension so it must be equal to  $F^{\alpha}$ .  $F^{\alpha}$  must be equal to  $KH$ .

So, now this means, we have not yet used the non-Galois of  $KH$  over  $F$ . We are only using the fact that 3 is prime. So, let capital  $F_X$  be the irreducible polynomial of  $\alpha$  over  $F$ . Now since  $F^{\alpha} : F$  is 3, degree of  $F$  is 3 because degree of  $F^{\alpha}$  over  $F$  is simply the degree of the irreducible polynomial of  $\alpha$  which is  $F$ . So, this is going to be my cubic irreducible polynomial.

So, the claim is  $K$  is equal to the splitting field of  $F$  over capital  $F$ . So, this proves the problem so this solves the problem. Why does it solves the problem? This solves the problem because, I am asked to show that  $K$  is the splitting field of irreducible cubic polynomial. It is a cubic polynomial, cubic means degree 3 of course. It is irreducible by choice because it is the irreducible polynomial of an element so if I show that  $K$  is the splitting field, I am done.

(Refer Slide Time: 32:16)

Pf of claim: (i)  $f$  splits completely in  $K[X]$  :  
Reason:  $K/F$  is normal and  $f \in F[X]$  has a root  $\alpha \in K$   
(and  $f$  is irr)  
So  $f$  splits completely in  $K[X]$ .  
Let  $\alpha_1 = \alpha, \alpha_2, \alpha_3 \in K$  be the roots of  $f$  in  $K$   
(Note:  $\alpha \in K$  is separable over  $F \Rightarrow f$  has distinct roots in  $K$ )  
(ii)  $K = F(\alpha_1, \alpha_2, \alpha_3)$

So, why is this? So, the proof of this claim, it is very easy to prove this claim and it is where, in this proof we are not using that,  $KH$  is not Galois over  $F$ . So, first point to note is,  $K$  splits completely... sorry  $f$  splits completely in  $KX$ . Why is this? Reason for this statement, why? Note that  $K$  over  $F$  is normal because it is given to be Galois, it is important that I take a Galois extension so it is a normal extension and  $F$  is a polynomial over the base field has a root  $\alpha$  in  $K$ . So,  $\alpha$  is in  $F(\alpha)$ , of course  $F(\alpha)$  is contained in  $K$ .

So, it has a root in  $K$  so one of the equivalent characterization of normal extensions is that, any polynomial, irreducible polynomial,  $F$  is irreducible also. Any irreducible polynomial which has 1 root splits completely. So, that proves the first statement. So, let  $\alpha_1$  which is of course  $\alpha$ ,  $\alpha_2$ ,  $\alpha_3$  be the roots of  $F$  in  $K$  because it splits completely, remember there are 3 distinct roots also because it is a normal Galois extension, it is separable so there are 3 distinct roots. So, call them  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$ .

So, know that  $F$  is separable, rather I will say  $\alpha$  in  $K$  is separable over  $F$  so  $F$  has distinct roots. Being the irreducible polynomial of a separable elements. So, the second statement to solve the problem is,  $K$  equals  $F(\alpha_1, \alpha_2, \alpha_3)$ . Remember splitting field is not just a field where the polynomial splits completely.

In addition, it must be generated by the roots because you can take a bigger field, it will not be a splitting field. So, here I claim that, it is a splitting field, I am not merely claiming that, a cubic irreducible polynomials splits in it. I am trying to show that, it is in fact, generated by the roots. So, let us look at where this can fit in our picture.

So, this is our picture, what we know is that, this is degree 3, this is degree 6 because its Galois group is  $S_3$  hence the degree is 6. So, remember of course we do know that, the order of the Galois group is the degree of the field extension because... and this is 6, this is  $S_3$  and this is 6 and this equality is because  $K$  over  $F$  is Galois. So, it is a degree 6 extension, I should have mentioned that before.

So, this is degree 6, this is degree 2, so that means  $K$  colon  $F^{\alpha_1}$  is 2. May be let me write it here, this is 6, this is 2. So, now  $F^{\alpha_1, \alpha_2, \alpha_3}$  is a intermediate field of degree 2 extension. So, this implies  $K$  equals  $F^{\alpha_1, \alpha_2, \alpha_3}$  or  $F^{\alpha_1}$  equals,  $F^{\alpha_1, \alpha_2, \alpha_3}$  because this is a degree 2 extension. These 2 numbers multiply to 2, that means you can either have, this is 2, this is 1 in which case this happens or this is 2 and this is 1, in which case this happens.

So, we are trying to show that, this happens and that this does not happens. And we are done now, right? Think why does not it happen? Because if  $F^{\alpha_1}$  equals  $F^{\alpha_1, \alpha_2, \alpha_3}$  then this of course is Galois, being a splitting field of a separable polynomial. So, this implies  $F^{\alpha_1}$  over  $F$  is Galois. This is exactly what I said, is not the case.

So, this is not Galois, this of course is  $F^{\alpha_1}$  so if  $F^{\alpha_1}$  over  $F$  is Galois, the corresponding sub-group will be normal but we know that, in order to sub-group of  $S_3$  is not normal so this is not Galois, so this is wrong. So, if this happens, we get a contradiction hence  $K$  equals and  $K$  is the splitting field of  $f$  as required.

So, we did produce that irreducible cubic polynomial,  $f$  is irreducible cubic polynomial whose splitting field is exactly  $K$  which is what I am trying to show.  $K$  is the splitting field of an irreducible cubic polynomial and we showed that here. So, let me stop this video here, with this problem. And we have few more problems that I want to do which apply the main theorem of Galois Theory. Thank you.
