Characterization of Solvability – Part 2

Welcome back. In the last class, we proved that Galois extension of degree 6 is always solvable.

(Refer Slide Time: 0:25)

Prop Let K/F be a cyclic extension (i.e., K/F is Galois and $\text{Gal}(K/F)$ is cyclic)
 Let $\alpha \in L$ where L is an extn of K . Then $K(\alpha)/F(\alpha)$ is also a cyclic extn
 and $[K(\alpha):F(\alpha)]$ divides $[K:F]$.

Prf: $G = \text{Gal}(K/F)$.

(i) $K(\alpha)/F(\alpha)$ is Galois: K is the sp fld of a separable poly $f \in F[X]$.
 Say $K = F(\alpha_1, \alpha_2, \dots, \alpha_r)$ where α_i are roots of f .
 Then $K(\alpha) = F(\alpha)(\alpha_1, \dots, \alpha_r)$ and $f \in F[X] \subseteq F(\alpha)[X]$.
 So $K(\alpha)$ is a sp fld of a sep poly over $F(\alpha)$.
 $\therefore K(\alpha)/F(\alpha)$ is Galois.

Diagram illustrating the tower of fields:
 $\begin{array}{c} K(\alpha) \\ | \\ K \\ | \\ F(\alpha) \\ | \\ F \end{array}$
 The extension $K(\alpha)/K$ is cyclic, and K/F is cyclic.

Along the way we proved this important theorem, which says that if you have a cyclic extension and you are joined in alpha to both fields in the extension, you also get a cyclic extension and the degree of the new extension divides the degree of the old extension. So, the goal today is to the following theorem.

(Refer Slide Time: 00:43)

So, let me write down the theorem and we will spend the whole class proving this. Let F be field of, let F be a subfield of $\mathbb{C}$, let α in capitals α be a complex number be algebraic over F . So, then the following are equivalent. The 3 statements that I will make are all equivalent to each other. α is solvable over F which is to say that there exists a tower. I am going to write the tower as follows. So, F equals F_0, F_1, F_r such that F_i over F_{i-1} so, so let me write like this. A simple radical for all i and α is in F_r . So, it is simply saying that α is solvable over F means α is in a radical extension of F but that radical expression must be the end of a tower of simple radical extension. So, this is just the definition.

The second statement is, there exists a tower. So, in all 3 statements, there are towers with the differing properties. There exists a tower of fields. So, let us call this F equals L_0, L_1 contained in L_n such that of course, α is in the end of them and each of the extensions is abelian that is Galois plus Galois group is abelian as we know very well an adjective which is used for groups, if you use it for field extensions, that means that field exploration is Galois and the Galois group has that adjectives. So, in this case, it is the Galois and the Galois group is abelian.

In the third statement is exactly as to except that the word abelian is replaced by cyclic. There exists at tower of fields. It is a F again starting with F , now K_0, K_1 , all the way up to K_m , let us say such that of course α is in the last one and each K_i over K_{i-1} is cyclic which is to say Galois plus Galois group is cyclic. So, that is the 3 statements. So, just stare at this. It is

important that you understand the first statement has to do with solvability by radicals as understood before Galois, as understood for hundreds of years before Galois, 2 and 3 have to do with Galois Theory, which is Galois' ingenious idea to connect field theory with group theory.

So, 2 and 3 are really group theoretic statements saying that there are towers of extensions, there with extensions being either abelian or cyclic. So, it is important that we prove this equivalence and then we will attack the possibility of solving quintics by radicals via 2 and 3. So, we have to settle once and for all the equivalent of these 3 statements.

(Refer Slide Time: 04:52)

P1. (1) $\Leftrightarrow$ (2): Let $F = F_0 \subseteq F_1 \subseteq F_2 \subseteq \dots \subseteq F_r$;
 Suppose $F_i = F_{i-1}(\alpha_i)$ with $\alpha_i \in F_{i-1}$ (meaning of F_i/F_{i-1} being simple radical)
 Let $s_1, s_2, \dots, s_r$ be primitive n_1 -th, n_2 -th, $\dots$, n_r -th roots of unity (in $\mathbb{C}$)
 We add $s_1, \dots, s_r$ to all F_i

Consider the following tower:

So, I will now prove the equivalence of this. Some of this is essentially coming from the previous class where we proved that cyclic extensions are solvable. So, let us see. So, we are assuming that, we are assuming that this is the new thing really, 1 to 2 is new, 2 to 3 is trivial, 3 to 1 is essentially done by us. So, let us do 1 to 2 first because we new so we are assuming that alpha is solvable. So, let F contained in F_1 contained in F_2 contained in F_r .

So, alpha is in F_r and suppose each F_i because each F_i or F_i minus 1 is a simple radical extension suppose F_i is generated over a F_i minus 1 with by alpha i with alpha i power n_i in F_i minus 1. This is the meaning of the extension being simple radical. I am just giving names to the generators and the exponents because we have now our extensions so we have to keep track of the all the things. So, we say that F_1 is generated over F_0 by alpha 1 and alpha upon power n_1 is in F_1 or F_0 and so on. So, this is the notation.

Now I am going to consider the following roots of unity. So, let, so remember we have n_1 through n_r and α_1 to α_r coming from this tower. So, we take the corresponding n th roots of unity. Primitive n_1, n_2, n_r th roots of unity. We can take them in $\mathbb{C}$ because we are working with subfield of $\mathbb{C}$ now. So, we have completely switched our characteristic to 0 here and subfields of $\mathbb{C}$ in fact. So, these are primitive. If n_1 is 2, I take primitive second root which is minus 1, of course that is already in F but if n_2 is 3, I will take ω , if n_3 is 4, I will take i and so on. So, these are those roots of unity.

(Refer Slide Time: 7:41)

Consider the following tower:

$$F_0 = F \subseteq F_1 \subseteq F_2 \subseteq \dots \subseteq F_r$$

where each extn is abelian.

Claim: This is a tower where each extn is abelian.

Ex: $F_0 \subseteq F_1 \subseteq F_2 \subseteq \dots \subseteq F_r$ where each extn is abelian.

Similarly: $F_0(S_{n_1}, S_{n_2}) / F_0(S_{n_1}, S_{n_2})$ are all abelian $i=1, \dots, r$.

Recall: $\text{Gal}(K/F) \subseteq (\mathbb{Z}/n_i\mathbb{Z})^*$

what about this?

Now consider following tower. So, I am going to write down the tower and I will carefully look at this. So, first I will do F_0 . So, let me try to squeeze this here. I do F_0 adjoin ζ_{n_1} , then F_0 adjoined $\zeta_{n_1 n_2}$. So, maybe I will just go to the next page because I want to squeeze everything in the same page. So, consider the following tower. So, what I will start with F_0 which is of course F . Remember the given tower is this. I am going to add all these n th roots to F_0 because I want to use our original theorem about extensions.

So, then I will do $F \zeta_{n_1} F \zeta_{n_1} \text{ comma } \zeta_{n_2}$, F_0 and I will one by one attach all of them and finally attach ζ_{n_r} and now, I will put $F_1 \zeta_{n_1}$, remember F_0 is contained in F_1 . So, I will just add all of them to F_1 also and keep doing this and finally I will do $F_r \zeta_{n_1} \zeta_{n_2} \dots \zeta_{n_r}$. So, I have changed the original fields completely. So, originally, we have this. So, basically, we add ζ_{n_1} to ζ_{n_2} to all f_i . So, for the first one, I just break the addition into one by one.

Now we want to claim that this is an extension where each, this is a tower where each extension is abelian. Thereby proving 2. So, of course, alpha is in here. So, alpha is in F_r . So, alpha is in F adjoined this. You are only enlarging the field. So, alpha will remain here and 2 says, there is a tower of abelian extensions with alpha being in the last one and here is the tower with alpha in the last one. So, why is this? Why is each of them abelian? So, one by one, let us check. What about F_0 contained in $F_0(\theta_1)$. This is a cyclotomic extension. So, abelian. So, this is covered in our class about cyclotomic extensions.

In general, every time you have a cyclotomic extension, recall from, so if you have cyclotomic extension, it is a the Galois group is isomorphic to a subgroup of $\mathbb{Z} \bmod n\mathbb{Z}^*$. This is abelian. So, this is abelian. So, this is just, this is exactly the result we proved in the corresponding, I mean the theorem in cyclotomic extensions class. So, these is abelian. So, let me write that here. This is abelian. What about this? This is also abelian of course because this is also a cyclotomic extension. You are adding zeta into $F(\zeta_{n_1})$. So, this is abelian. This is abelian. So, all of these are abelian. So, up to this everything is abelian.

So, similarly $F(\zeta_n)$, $F(\zeta_{n_i})$ over $F(\zeta_{n_1})$, $\zeta_{n_i}^{n_i-1}$ are all abelian. So, from i equal to 1 to r . So, these are all abelian. What about the next one? So, this, let us focus on this. What about this? I claim this is also abelian. Now here is where we will use Kummer theory.

(Refer Slide Time: 12:44)

Handwritten notes on a whiteboard:

- What about $F_0(S_1, \dots, S_r) \subseteq F_1(S_1, \dots, S_r)$?
- $F_0(S_1) = F_1$ — $F_1(S_1, \dots, S_r)$
- radical / F_0 — $F_0(S_1, \dots, S_r)$
- also radical, why? ✓
- $F_1(S_1, \dots, S_r) = F_0(S_1, \dots, S_r)(\alpha_1)$
- $\alpha_1^{n_1} \in F_0 \subseteq F_0(S_1, \dots, S_r)$
- this is a radical extn; $F_0(S_1, \dots, S_r)$ contains $S_1 \rightarrow$ primitive n_1 th root of unity;

So, what about this? By the first observation what we have is F_1 over F_0 , this is cyclic, this is radical. So, I now claim this is also, radical. So, why is that? So, think about this, why is that radical? That is radical because F_1 is F_0 adjoined α^1 . So, F_1 of ζ_{n^1} , ζ_{n^r} is F_0 of $\zeta_{n^1} \zeta_{n^r}$ adjoined α^1 . So, the same thing will generate this field over this field and α^1 power n^1 is in F_0 . This implies, of course, it is in F_0 power ζ_{n^1} to ζ_{n^r} .

So, this is also a radical extension. So, that is okay, but now we have a radical extension so, this is a radical extension and what is a degree of that extension? So, this radical extension contains the base of this radical extension contains a primitive contains ζ_{n^1} which is a primitive n th root of unity, n^1 th root of unity.

(Refer Slide Time: 15:24)

Pf of this follows from the ...

Theorem 1: Let $n \geq 1$ be an integer. Let F be a field containing a primitive n th root of unity. Let $a \in F$, let $K = \text{Sp. fld of } X^n - a \text{ over } F$. Then

(1) K/F is a cyclic ext; and

(2) $|\text{Gal}(K/F)| = n \Leftrightarrow X^n - a$ is irr over F .

Theorem 2: Let $n \geq 1$, and let F be a field containing a primitive n th root of unity. Let K/F be a cyclic ext of $n = [K:F]$. Then K is the sp. fld of an irr poly $X^n - a$ over F (i.e., $a \in F$).

Handwritten notes:
 Kummer $\Rightarrow$ cyclic
 cyclic $\Rightarrow$ Kummer

So, now here is some general facts. So, the, I claim that so what we have now shown is so let me go back to the Kummer extension theorem that we proved it. So, let me explain how we use that. I think I went way back. So, this is the Kummer extension theorem. So, let us look at the main theorem and in fact, I wanted to look at the theorem 2. So, if you have field containing a primitive n th root of unity and N is the extension of that, then K is the splitting field of that but okay, actually I do want theorem 1.

So, you have a field containing primitive n th root of unity and K is splitting field of $X^n - a$. Then it is cyclic. So, what I want is this. So, I want this statement. So, if I claim that in our situation the hypothesis is satisfied. F is a field containing a primitive n th root of unity. K is

the splitting field of $x^n - a$. Then that extension is cyclic. So, primitive n th root of unity and this is the splitting field of $x^n - 1$. So, I so let me just rewrite this.

(Refer Slide Time: 17:38)

So, F_1 that adjoin ζ_n to ζ_n is the splitting field. This is clear because F_1 is the splitting field of $x^n - a$. F_1 is the is a radical expression. It is not necessarily splitting field. So, F_1 over F_0 is not necessarily splitting field extension, not a normal extension. However, it is obtained by adjoining a root n th root of α but now in this new extension, you have adjoined n th root of α power n and hence you attached because ζ_n is there in the base field.

Once you attached, so basically what I am saying, is that let α be α_n power n , then all the n th roots of α are in $F_1 \zeta_n$. So, it is a splitting field and the base field contains sub ζ_n . Hence by theorem 1, in Kummer extensions class: $F_1 \zeta_n$ over $F_0 \zeta_n$ is cyclic and hence abelian. So, basically, my goal has always been to use the theorem 1 but in order to use that, I need my base field to have roots of unity, which I have achieved by adding them a priori. So, I hope this is clear.

So, the crucial thing is theorem 1 in Kummer theory. In order to apply theorem 1, we need the base field to contain primitive n th roots of unity, which I achieved by adding this. So, this is abelian. So, this is abelian. What about this? Exactly the same reason. This is also abelian except that we work with N_2 now because this is an extension a priori where in n^2 roots is attached. So, you perform the same logic F_2 or F_1 but F_2 adjoined all the roots, F_1 adjoined all the roots, the

relevant thing is only $\mathbb{Z}_n$ that is there. So, by theorem 1 of Kummer extension that is cyclic and hence abelian. So, everything is abelian.

So, this tower is a tower where each extension is abelian and hence 2 is proved. I hope this argument is clear. What we do is, take the original tower where every extension simple radical but figure out which roots of unity are required which come from the powers, the radicals which are attached in this simple radical extensions, attach the roots of unity for those n 's and then argue the initial cyclotomic extensions are all abelian by our cyclotomic extension theorem and after that, after F_0 after you attach all of them, you use Kummer Theory to argue that are all abelian. So, that proves 2.

(Refer Slide Time: 21:54)

(2) $\Rightarrow$ (3) claim: Given an abelian ext K/F , $\exists$ a tower $F = F_0 \subseteq F_1 \subseteq \dots \subseteq F_r = K$ st each F_i/F_{i-1} is cyclic. (Main thm)

Prf: Let $G = \text{Gal}(K/F)$. So G is abelian.
 Let H be a proper cyclic subgroup of G . Consider K^H/F .
 K/K^H is cyclic $\checkmark$
 K^H/F is abelian with $[K^H:F] < [K:F]$ (apply induction to K^H/F)
 we then induct on $[K:F]$.
 (1) $|G/H| > 1$.
 K^H/F is cyclic.

Now 2 implies 1 is trivial because remember what is 2. 2 is that there is a tower where the end field contains α and each is abelian. So, 2 is not trivial, 2 to 1 is not trivial. So, let me, so we have to prove something. So, we will show that given an abelian extension K over F , there exists a tower such that each F_i by F_i minus 1 is cyclic. So, this is more or less trivial because what do we do? So, claim is this. Prove so let G be the Galois group of the original abelian extension. So, this G is abelian. K over F is abelian so it is Galois with Galois group abelian. So, let H be a proper sub group, G proper cyclic subgroup of G .

Of course, G is cyclic then we are done. If G is cyclic then we are done because K over F is a cyclic extension. So, then we consider K , K power H and F . Remember this is cyclic. So,

actually what I mean is, I do not need proper cyclic subgroup of G , proper cyclic proper cyclic subgroup. So, this G , this is Galois extension, I mean everything is abelian. So, this is Galois extension with Galois group $G \bmod H$, and this is strictly more than 1 because it is a proper subgroup. So, by induction, so apply induction to this.

So, note that KH , so K over KH is cyclic. This is okay. KH over K or KH over F is Galois, with abelian Galois because G 's abelian is important here. So, every group is subgroup is normal. So, every intermediate field over the base field is Galois. So, the main theorem is required here. So, this is abelian with the degree strictly less than the original extension, so we then induct. So, this can be populated by a series of cyclic extensions. You attach one more to get the desired cycle extension.

So, this implies 1 because if you are given a tower of abelian extensions, you expand this tower by putting in lots of subfields where each extension is cyclic. Similarly, you do that for L_1 contained in L_2 . L_{n-1} contained in L_n and you get a much bigger tower but with each of the intermediate extensions being cyclic. So, 2 implies 3, this is not 2 implies 1. I am trying to prove 2 implies 3. So, given an abelian extension, it is rather easy to get a tower of cyclic extensions. So, you do that for each abelian extension and you have done.

(Refer Slide Time: 26:04)

(3) $\Rightarrow$ (1): We are given: $F = K_0 \subseteq K_1 \subseteq \dots \subseteq K_n = F$
 each K_i/K_{i-1} is cyclic. let $n_i = [K_i : K_{i-1}]$.
 $\hookrightarrow \zeta_{n_1}, \dots, \zeta_{n_n}$: primitive n_1 th, n_2 th, $\dots$, n_n th roots of unity.
 $K_0 \subseteq K_0(\zeta_{n_1}) \subseteq K_0(\zeta_{n_1}, \zeta_{n_2}) \subseteq \dots \subseteq K_0(\zeta_{n_1}, \zeta_{n_2}, \dots, \zeta_{n_n}) \subseteq \dots \subseteq K_n(\zeta_{n_1}, \zeta_{n_2}, \dots, \zeta_{n_n})$
 what about this? First: it is cyclic, Second: base field contains ζ_i .
 This is the desired tower of simple radical extns!

$$K_0(\zeta_{n_1}, \dots, \zeta_{n_n}) = K_1(\zeta_{n_1}, \dots, \zeta_{n_n})$$

Finally, 3 implies 1 and this is something that we have done essentially in a special case in the previous video where we prove that a Galois extension about 6 is solvable. So, this is crazy

because the idea is that we are given so let me just summarize the method. So, F_0 is, f is K_0 , K_1 , K_m or n , K_m such that α is in K_m . Each K_i over K_{i-1} is cyclic. So, what do I do here? So, what we do here is we let n_i be the extension degree of K_i and K_{i-1} and let us choose ζ_{n_1} to ζ_{n_m} , primitive they are all complex numbers, primitive n_1 , n_2 th, n_m th, roots of unity and then attach all of them to K_0 .

So, first we do K_0 , adjoined $K_0 \zeta_{n_1}$ and $K_0 \zeta_{n_1}, \zeta_{n_2}$, $K_0 \zeta_{n_1}, \zeta_{n_m}$ and then you do, $K_1 \zeta_{n_1}, \zeta_{n_m}$, all the way up to $K_m, \zeta_{n_1}, \zeta_{n_m}$, just like in the first case 1 implies 2. Here, the only difference is the n_i we have chosen are the degrees of the extensions. In 1, we have chosen the n_i to be the radicals we needed to take So, now you claim that this is the desired tower of simple radical extensions. Why is this?

Of course this is simple radical because it is a cyclotomic extension. $\zeta_{n_1}^{n_1}$ is 1 so that is in K_1/K_0 this is simple radical. This is simple radical because these are all obtained by adding an n th root of unity. A primitive n th root of unity n_i th root as n_i . So, do they do not present any problem. What about this and here is where the hopefully the Galois group extension of order 6 will be recalled to your mind now.

(Refer Slide Time: 29:15)

$$\begin{array}{lcl}
 K_1 = K_0(\zeta_{n_1}) = K_0(\zeta_{n_1}, \zeta_{n_2}) & = & K_1(\zeta_{n_1}, \dots, \zeta_{n_m}) \\
 \text{cyclic} \quad | \text{cyclic} & & \text{cyclic} \\
 K_0 = K_0(\zeta_{n_1}) = K_0(\zeta_{n_1}, \zeta_{n_2}) & = & K_0(\zeta_{n_1}, \dots, \zeta_{n_m}) \Rightarrow \zeta_{n_1}^{n_1} \\
 \text{(Prop)} & & n_1' \text{ divides } n_1 \\
 & & \Rightarrow \zeta_{n_1}^{n_1'} \text{ is a primitive } n_1' \text{th root of unity}
 \end{array}$$

So, we have K_1 over K_0 is cyclic. That is given to be that case. So, this is cyclic. Adjoined all of these so basically, I will argue just for complete clarity. So, this is cyclic by the proposition. Remember the proposition we proved. So, if your cyclic extension you attach something, it will

remain cycling and you attach 1 more, this is also cyclic because this is cyclic, you apply the proposition and finally $K_1 \zeta_{n_1}, \zeta_{n_m}$ over $K_0 \zeta_{n_1}, \zeta_{n_m}$, they are all cyclic. So, this is cyclic. So, this is cyclic.

First, it is cyclic. It is cyclic, but the base field contains ζ_{n_1} and base field contains, second argument is, based field contains ζ_{n_1} which is the primitive n th root of unity, and now remember this is extension of degree n_1 . So, this is a divisor of n_1 by the proposition that we proved. So, this, whatever this n_1 prime is, n_1 prime divides n_1 So, this implies some power of ζ_{n_1} , I think it is n_1 by n_1 prime is a primitive n_1 th prime root of unity. So, I will write this here. So, this is an extension of degree n_1 prime where the base field contains degree ζ_{n_1} prime because once you have a primitive eighth root of unity, some power of it will be a primitive fourth root of unity.

So, once you have a primitive n th root of unity, a suitable n_1 prime divides n_1 , suitable power of the primitive n th root of unity will be a primitive n_1 prime root of unity. So, this is a cyclic extension of degree n_1 prime with base field containing a primitive n_1 prime root of unity. So, now let us go back to one final time the lectures on cyclotomic extensions, Kummer extensions and let us look at theorem 2. So, we have a field containing a primitive n th root of unity and an extension containing a cyclic extension of that degree n where will contains an n th root of unity. Then K is the splitting field of some polynomial like this. That means K over F is irreducible. K over F is simple radical.

(Refer Slide Time: 33:03)

So, by theorem 2 Kummer extensions, so I think page 42 in this notes, K adjoined, K_1 adjoined is a simple radical extension because it is obtained by adding n_1 th power of n_1 th root of some element of this field. So, similarly, so this is simple radical, this is simple radical, this is simple radical. So, everything is simple radical. So, alpha which is in, of course alpha is in here in K_m and so I will just write it one more time over $F_0 = K_0$ which is F is a radical extension. So, alpha is here and these radical extensions because this is a radical extension of this because there is a tower starting with this, ending with this and where each extension is a simple radical extension. This is radical extension containing alphas so, alpha is a solvable over F .

So, this proves the theorem that I started this class with and now we are ready to attack the question of solving polynomials by radicals. More precisely given a polynomial, is it solvable or not, we want to address and in the next video, we are going to settle the case of degree 1, 2, 3, 4 and then after that we will tackle the case of degree 5. So, let me stop today here and in the next class we continue with solving polynomials by radicals. Thank you.
