Problem Session - Part 12

(Refer Slide Time: 0:19)

Now any elt $\sigma \in G$ permute roots of h separately.
 Using this factorization, conclude that G is not transitive.
 (Last part: exercise)

⑤ Let $f \in F[x]$ be irr. If one root of f is soluble over F (FSC) then f is soluble (i.e., all roots of f are soluble).
 Pf: $\alpha \in E$ is a soluble root of f .
 $F \subseteq F_1 \subseteq \dots \subseteq F_r \xrightarrow{\text{Theorem}} F \subseteq F_r \subseteq L$

Welcome back we are in a problem session now. And as I told you, we have completed the content of the course, we have developed Galois theory, defined Galois theory, proved main theorem and talked about Kummer extensions, cyclotomic extensions and so on, and then proved the main result of that Galois theory achieves and which was a long standing problem that is solved, which is that there are quintic polynomials that cannot be solved by radicals.

So, we did all that, we gave examples and now, we are in the middle of doing several exercises to make sure that we understand the concepts better. So, I will do one or two more videos to do more problems.

(Refer Slide Time: 0:54)

⇒ All roots of J are
⑥ Let p be a prime. Let K/F be a Galois extn st $[K:F] = p^k$ for some positive int k . Show that K/F is solvable.
Solu: By Galois's theorem: K/F is solvable $\Leftrightarrow \text{Gal}(K/F)$ solvable.
 $\text{Gal}(K/F)$ is a 'p-group', i.e., a gp of order p^k .

So, let me just start with this following problem. Let p be a prime and let K over F be a Galois extension such that the degree of the extension is a power of p . So, p power k for some positive integer k . So, the Galois group is in other words a p group in the language of group theory, so show that K over F is solvable. That means, every element of K is soluble over F that is what it means.

So, by our main theorem, our theorem by Galois theorem let me call it, that says that an extension is Galois is solvable if and only if its Galois group is solvable. So, this is a purely group theoretic phenomenon. But Galois K over F is a 'p group' that is a group of order p power k .

(Refer Slide Time: 2:30)

Such groups are solvable: $|G| = p^k$.
Consider the center of G : $Z(G) = \{g \in G \mid ag = ga \forall a \in G\}$.
Fact: $Z(G)$ is a normal, abelian subgroup of G .
If G is a p -group, then $Z(G)$ is non-trivial, i.e., $|Z(G)| > 1$.
 $Z(G)$ is solvable & $G/Z(G)$ is a p -gp of order $|G/Z(G)| < |G|$.

So, now, these such groups are solvable. So, that I will let you I mean, this is a simple statement, but I will give you a hint on how to proceed with this. So, of course, we know that let us say G is power k by Sylow's theorems for example, or Cauchy's theorem in fact, by Cauchy's theorem G has an element of order p . So, actually, let me be careful here, what I want to do is consider the center of G which is all elements which commute with everything, so, g and G such that ag equals ga for all a in G .

So, now a group theory fact is a normal subgroup, this is always true and for p -groups then $Z(G)$ is non-trivial. So, that is, its order is at least 1, at least 2. So, now using these facts, because it is abelian $Z(G)$ is solvable and $G/Z(G)$ is a p -group, because order of $Z(G)$ will also be a power of p . So, this will be p power k divided by some smaller power of p which is also p power. So, this is a p -group of order strictly less than order of G , because $Z(G)$ is non-trivial. So, this is a strictly smaller subgroup, a proper subgroup.

(Refer Slide Time: 4:41)

If G is a p -group, then $Z(G)$ is non-trivial.
 $Z(G)$ is solvable & $G/Z(G)$ is a p -gp of order $|G/Z(G)| < |G|$
 By induction, $G/Z(G)$ is solvable $\Rightarrow G$ is solvable $\checkmark$
 • $[K:F] = 10$, and K/F is Galois $\Rightarrow K/F$ solvable.
 Show: Any gp of order 10 is solvable: $|G| = 10$. H
 $\Rightarrow G$ has a subgroup of order 5
 $\& H$ is normal in G .
 $\{1\} \subseteq H \subseteq G \Rightarrow G$ is solvable.
 $\begin{matrix} 3/5 & 2/5 \end{matrix}$

So, by induction hypothesis, I mean I have not set it up properly, but by induction, you first show that for any p group of order p is solvable, that is clear, because it is abelian. So, this will be solvable. So, it is a p group of smaller order, so, $Z(G)$ is solvable, this is solvable and hence G is solvable, so that solves this.

A similar problem I want to give. I do not want to call it a new thing, new numbering, but let us say K colon Q is 10 and K over Q is Galois. In fact, you can replace Q by F , implies K colon F is solvable. So, all you need to do is that show any group of order 10 is solvable and this is clear because, if G has order 10 it could be non abelian, it could be D_5 .

But, we do know that G has a subgroup of order 5, subgroup H of order 5 and H has to be normal because it is index 2. So, you can consider the series one containing, contained in H contained in G . So, this is quotient $Z \text{ mod } 5$, Z , this is normal and quotient is $Z \text{ mod } 5$, and this is $Z \text{ mod } 2$. So, this is a series that will give you the solvability of G and hence solvability of the extension K over F . So, the next problem I want to talk about is a famous problem. So, this is not so much as a problem, but in introduction I will cover some exercises as part of this.

(Refer Slide Time: 6:44)

⑦ Inverse Galois problem: Given a finite group G ,
does there exist a Galois extension $K/\mathbb{Q}$ s.t.
 $\text{Gal}(K/\mathbb{Q}) \cong G$.
This is a very famous problem; open in general.

⑧ Inverse Galois problem: Given a finite group G ,
does there exist a Galois extension $K/\mathbb{Q}$ s.t.
 $\text{Gal}(K/\mathbb{Q}) \cong G$.
This is a very famous problem; open in general.
It is known in some cases: $\left\{ \begin{array}{l} G = D_2, D_4, A_4, S_4, S_5, S_p, \text{prime} \\ S_3, A_3, S_2 \end{array} \right.$
We have constructed Galois extensions $K/\mathbb{Q}$ for all these groups.

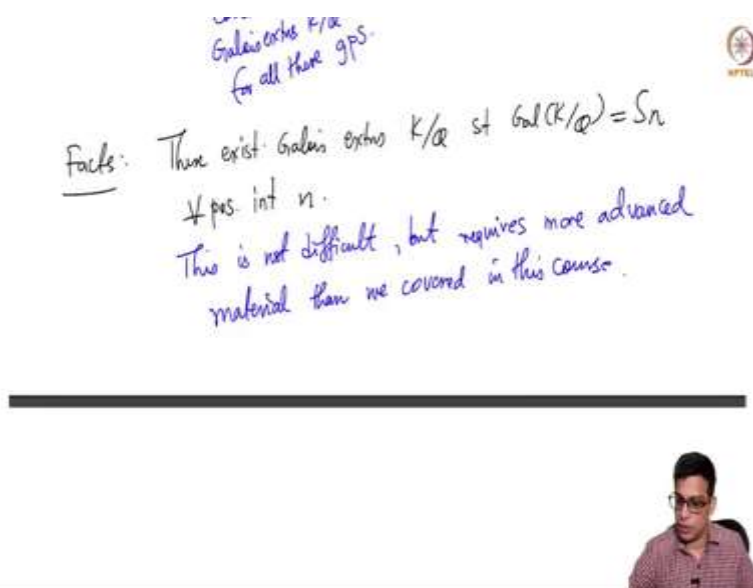

So, there is a famous open problem in Galois theory, it is in fact, a very famous problem. And solving this will make you instantly famous. So, inverse Galois conjecture or problem, it is not a theorem of course. So, given a finite group G does there exist a Galois extension of $\mathbb{Q}$. So, it is important that the base field is $\mathbb{Q}$, such that its Galois group is G . So, this is a very famous open problem, it is open in general, this is a famous problem, open in general. Meaning there is no general, there is no proof that for every group, there is such a Galois extension of $\mathbb{Q}$, so that is it is open.

And it is a very important problem in mathematics, it led to, working on this led to a lot of deep and beautiful mathematics. However, it is known in some cases, just to give you a flavor of what we can do. For example, if G is D_2 , D_4 , A_4 , S_4 , S_5 , S_p , p prime. So, we have done all this, S_3 , A_3 , we have constructed and $S_2 \cong \mathbb{Z}/2\mathbb{Z}$. So, all these cases Galois extensions for all this, for all these groups, we have done good that is not difficult. D_2 , D_4 , A_4 , S_4 were covered in the case of quartic irreducible polynomials.

And of course, we also need to put C_4 here. That is also in quartic, S_5 we have constructed shows that there are quintics that are not solvable. More generally, we do an S_p for primes and S_3 , A_3 for cubics and S_2 for quadratics.

(Refer Slide Time: 9:48)

Handwritten notes on a slide:

Galois extns $K/\mathbb{Q}$
for all these gps.

Facts: There exist Galois extns $K/\mathbb{Q}$ st $\text{Gal}(K/\mathbb{Q}) = S_n$
for pos. int n .
This is not difficult, but requires more advanced
material than we covered in this course.

So, these are some general theorems that are known or facts, let me simply call them as facts, there exist Galois extensions, K over $\mathbb{Q}$ such that $\text{Gal}(K/\mathbb{Q}) = S_n$. So, what we have done for S_p can be done more generally for S_n , for all integers, positive integers n . So, we have done here for 1, 2, 3, 4, 5. And every prime after that 7, 11 and so on. But this is significantly more difficult, so this requires, so this is not difficult, it is not difficult in the sense that it is not a theorem, it is not a research paper, this is not difficult but requires more advanced material.

So, it requires either some algebraic number theory or committed to algebra. Then we are, then what we did in this course? But it is good to keep this in mind. So, there is a Galois extension of rational numbers with Galois group S_n and also for A_n , so that it is also known.

(Refer Slide Time: 11:17)

material than we covered

- ② Known for A_n
 - ③ Known for solvable gps G (Shafarevich)
- Ex: Given an abelian gp G , show that $\exists$ a Galois ext $K/\mathbb{Q}$
 st $\text{Gal}(K/\mathbb{Q}) = G$

So, I will simply write like this known for A_n also. And it is also known for solvable groups. This is a theorem of famous mathematician called Shafarevich. What I want to do now is exercise given an abelian group. This we can do now, modulo some general group theory, show that there exists a Galois extension K over $\mathbb{Q}$ such that $\text{Gal}(K/\mathbb{Q}) = G$. So, after we do this exercise, if you take stock of the inverse Galois problem, you can do for symmetric groups, you can do for alternating groups, you can do for solvable groups, and you can do for abelian groups, the abelian groups is the, is something we can do.

(Refer Slide Time: 12:19)

st $\text{Gal}(K/\mathbb{Q}) = G$

Soln: First assume $G \cong \mathbb{Z}/n\mathbb{Z}$. Choose a prime p st.
 $p \equiv 1 \pmod{n}$, i.e., n divides $p-1$

Existence of such p is guaranteed by Dirichlet's theorem about primes in arithmetic progression

← $\{a, a+d, a+2d, a+3d, \dots\}$
 $(a,d)=1$

(there are infinitely many primes)

Soln: First assume $G \subseteq \mathbb{Z}/n\mathbb{Z}^*$. Choose $p \equiv 1 \pmod{n}$, i.e., n divides $p-1$.

Existence of such p is guaranteed by Dirichlet's theorem about primes in arithmetic progression.

There are infinitely many primes $\leftarrow \{a, a+d, a+2d, a+3d, \dots\}$ ($(a,d)=1$)

$G = \text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q}) \cong (\mathbb{Z}/p\mathbb{Z})^* \cong \mathbb{Z}/(p-1)\mathbb{Z}$.

Since n divides $p-1$, $\exists$ a subgroup H of G of order $\frac{p-1}{n}$.

$\text{Gal}(K/\mathbb{Q}) = G/H \cong \mathbb{Z}/n\mathbb{Z}$.

$\mathbb{Q}(\zeta_p)$
 $\downarrow$
 $K = \mathbb{Q}(\zeta_p)^{H/H}$
 $\downarrow$
 $\mathbb{Q}$

But in general there is no construction for arbitrary groups. So, this is something that I will do now, which is not, so I will actually do the cyclic case first, because general case is essentially follows from the cyclic case. So, assume that G is a cyclic group, choose a prime p , such that $p \equiv 1 \pmod{n}$, that is n divides p minus 1. So, n divides p minus 1, so, I want this.

So, now, the existence of such p is a theorem if such p is guaranteed by Dirichlet's theorem about primes in arithmetic progression. Dirichlet proved that if you give, if you start with any arithmetic progression, something like $a, a + d, a + 2d, a + 3d$ and so on, this, there are infinitely many primes in this. So, you have to assume a and d are co prime, there are infinitely many primes. So, you can prove this, this is Dirichlet's theorem, not prove this, but this is a fact and it is a famous theorem. It is not easy to prove this. So, now, let us choose that p , I am not going to discuss this for now.

So, choose such p and $\mathbb{Q}(\zeta_p)$ over $\mathbb{Q}$. So, by what we know already from cyclotomic extensions, $\mathbb{Q}(\zeta_p)$ over $\mathbb{Q}$ is isomorphic to $\mathbb{Z}/p\mathbb{Z}^*$, which is of course isomorphic to $\mathbb{Z}/(p-1)\mathbb{Z}$. So, because p is prime the group of units in $\mathbb{Z}/p\mathbb{Z}$ is all nonzero elements so, that is $\mathbb{Z}/p\mathbb{Z}^*$. So, since n divides p minus 1 there exists a subgroup. So, let us call this G , there exists a subgroup H of G of order $\frac{p-1}{n}$.

So, now let us take the fixed field of that. So now, this, because this is an abelian extension every subgroup is Galois. So, this is every intermediate field is Galois over $\mathbb{Q}$. This is Galois with what is the Galois group of let us call this K . What is Galois group of K over $\mathbb{Q}$? This is $\mathbb{Z}/n\mathbb{Z}$.

minus 1 $\mathbb{Z}$ modulo $\mathbb{Z}$ mod. Basically $G \bmod H$, which is a cyclic group, because quotient of a cyclic group is cyclic, it is order n rather I should write p minus 1 by n here, it is p minus 1 divided by p minus 1 by n . So, it is $\mathbb{Z} \bmod n \mathbb{Z}$.

So, this is the desired, this is the Galois extension we are looking for. So, this is the Galois extension we are looking for, we are looking for a Galois extension of $\mathbb{Q}$ with Galois group being this cyclic group of order n . So, this is done.

(Refer Slide Time: 16:41)

Sketch for general abelian gps: G abelian (finite)
 Structure theorem of finite abelian gps: $G \cong \mathbb{Z}/n_1\mathbb{Z} \times \dots \times \mathbb{Z}/n_r\mathbb{Z}$
 Choose distinct primes $p_1, \dots, p_r$ st $n_i \mid p_i - 1 \forall i$ (Dirichlet)
 $\tilde{G} = \mathbb{Z}/p_1\mathbb{Z} \times \mathbb{Z}/p_2\mathbb{Z} \times \dots \times \mathbb{Z}/p_r\mathbb{Z}$
 $\tilde{G}^*$

Structure theorem of finite abelian gps: $G \cong \mathbb{Z}/n_1\mathbb{Z} \times \dots \times \mathbb{Z}/n_r\mathbb{Z}$
 Choose distinct primes $p_1, \dots, p_r$ st $n_i \mid p_i - 1 \forall i$ (Dirichlet)
 $\tilde{G} = (\mathbb{Z}/p_1\mathbb{Z})^* \times (\mathbb{Z}/p_2\mathbb{Z})^* \times \dots \times (\mathbb{Z}/p_r\mathbb{Z})^*$
 $m := p_1 \cdots p_r$ Consider $\mathbb{Q}(\zeta_m)$
 $\text{Gal}(\mathbb{Q}(\zeta_m)/\mathbb{Q}) \cong (\mathbb{Z}/m\mathbb{Z})^*$
 $\cong \tilde{G}$
 group theory fact
 $\therefore H = H_1 \times H_2 \times \dots \times H_r$ where

$$\begin{aligned}
 m &:= p_1 \cdots p_r \quad \text{Consider } \mathbb{Q}(\zeta_m) \\
 \text{Gal}(\mathbb{Q}(\zeta_m)/\mathbb{Q}) &\cong (\mathbb{Z}/m\mathbb{Z})^\times \\
 &\cong \tilde{G} \\
 H &\subseteq \tilde{G} : H = H_1 \times H_2 \times \cdots \times H_r \quad \text{where} \\
 H_i &\subseteq (\mathbb{Z}/p_i\mathbb{Z})^\times, |H_i| = \frac{p_i-1}{n_i}
 \end{aligned}$$

Now, quickly sketch for general abelian groups. I am not giving you the details, but this is more or less self-contained modulo these details. So, structure theorem for abelian groups of course, all our groups are finite here shows that. So, let us say G is abelian and finite always G can be factored as $\mathbb{Z} \bmod n_1 \times \mathbb{Z} \bmod n_2 \times \cdots \times \mathbb{Z} \bmod n_r$, any abelian group is a product of cyclic groups.

Now, choose primes p_1 through p_r , such that n_i divides $p_i - 1$. So, again this is possible. So, choose distinct primes. So, p_i is not equal to p_j for i different from j , so we can choose distinct primes like this and this is a consequence of Dirichlet's theorem. Now, consider $\tilde{G}$ to be $\mathbb{Z} \bmod p_1 \times \mathbb{Z} \bmod p_2 \times \cdots \times \mathbb{Z} \bmod p_r$. Now, $\tilde{G}$ is, so, let me for now say the following.

So, let us say m is equal to, let us take m to be product of these primes. So, then consider the Galois group, I mean the Galois extension $\mathbb{Q}(\zeta_m)$ over $\mathbb{Q}$, ζ_m is of course, a primitive m th root of unity. Then, Galois group of this is isomorphic to $(\mathbb{Z}/m\mathbb{Z})^\times$ which happens to be $\tilde{G}$. So, this is a fact because m has this decomposition and this is a group theory fact. So, I will proceed after, without saying anything further about this.

So, now construct H a subgroup of $\tilde{G}$ as follows. H is $H_1 \times H_2 \times \cdots \times H_r$, where H_i is inside $\mathbb{Z} \bmod p_i$. So, by the way, I think I made a mistake here. So, what I mean here is $\mathbb{Z} \bmod p_i$. So, I do not want to take $\mathbb{Z} \bmod p_i$, but $\mathbb{Z} \bmod p_i$, so I want to take starts here. So, H_i is a subgroup of this. And the cardinality of H_i is $p_i - 1$, which is the cardinality of this

divided by n_i , just like we did in the cyclic case. So, I am sorry, I am going over this fast, I hope you understood the cyclic case, and then this is just putting all of them together.

(Refer Slide Time: 20:25)

$$\begin{aligned}
 H \subseteq \tilde{G} : H &= H_1 \times H_2 \times \dots \times H_r \quad \text{where} \\
 H_i &\subseteq (\mathbb{Z}/p_i\mathbb{Z})^*, |H_i| = \frac{p_i-1}{n_i} \\
 \text{Fact: } \tilde{G}/H &= \mathbb{Z}/n_1\mathbb{Z} \times \mathbb{Z}/n_2\mathbb{Z} \times \dots \times \mathbb{Z}/n_r\mathbb{Z} \\
 &\cong \frac{(\mathbb{Z}/p_1\mathbb{Z})^*/H_1}{n_1/n_1} \times \dots \times \frac{(\mathbb{Z}/p_r\mathbb{Z})^*/H_r}{n_r/n_r} \rightarrow \frac{p_1-1}{p_1/n_1} \dots \frac{p_r-1}{p_r/n_r} \\
 &\cong \mathbb{Z}/n_1\mathbb{Z} \times \dots \times \mathbb{Z}/n_r\mathbb{Z}
 \end{aligned}$$

So, now, H is a subgroup of $\tilde{G}$ of index, index is a cyclic subgroup H is actually what I want to now say is that this I will let you verify is $\mathbb{Z} \bmod n_1 \times \mathbb{Z} \bmod n_2 \times \dots \times \mathbb{Z} \bmod n_r$, so this is a fact. Again, standard group theory facts. By the way, we constructed this, this is actually nothing but, this is nothing but $\mathbb{Z} \bmod p_1$ star modulo H_1 which will have this is $\mathbb{Z} \bmod p_r$ star modulo H_r , but because this is order p_1 minus 1 divided by p_1 minus 1 divided by n_1 .

So, this will be a cyclic group of order n_1 . So, and this will be order p_r minus 1 divided by p_r minus 1 by n_r . So, this will be a cyclic group of order $\mathbb{Z} \bmod n_r$. But this of course, is by construction $\tilde{G}$. So, this is fairly easy. So, now, we are done. So, now, all we need to take, maybe I will write here.

(Refer Slide Time: 22:03)

Now:

$$\tilde{G} \left(\begin{array}{c} \mathbb{Q}(\zeta_m) \\ | \\ \mathbb{Q}(\zeta_m)^H \\ | \\ \tilde{G}_H \cong G \\ | \\ \mathbb{Q} \end{array} \right) \text{ this is the extn we are looking for.}$$

$$\tilde{G} \left(\begin{array}{c} \mathbb{Q}(\zeta_m)^H \\ | \\ \tilde{G}_H \cong G \\ | \\ \mathbb{Q} \end{array} \right) \text{ extn we are looking for.}$$

- So every abelian gp is realized as a Galois gp over $\mathbb{Q}$.
- Inverse Galois problem asks if every finite gp can be realized as a Galois gp over $\mathbb{Q}$. (open in general)

Now, what we do? We have the field $\mathbb{Q}(\zeta_m)$ and we take the fixed field of H , over, this is G tilde, so, this is G tilde mod H which is G . So, this is the extension we are looking for. So, this completes the statement that every abelian group is realized as a Galois group over $\mathbb{Q}$. So, every abelian group is realized as a Galois group over $\mathbb{Q}$. So, this is a short way of saying that there is a Galois extension of $\mathbb{Q}$ whose Galois group is that abelian group.

So, now, inverse Galois problem asks, if every finite group can be realized as a Galois group over $\mathbb{Q}$. So, this is open in general and as I remarked earlier, it is true for abelian groups, it is true for symmetry groups, it is true for solvable groups, it is true for alternating groups and so on. So,

still it remains an open question for other kinds of groups. So, arbitrary non abelian groups. So, now, let us continue. So, let me do 1 or 2 more problems in this class, then I have one more video where I can finally wrap up the course.

(Refer Slide Time: 24:04)

⑧ Give an example of a field ext $K/\mathbb{Q}$ st $[K:\mathbb{Q}] = 4$
and $K/\mathbb{Q}$ has no nontrivial intermediate fields.
Check: Any such ext $K/\mathbb{Q}$ can't be Galois.

$\begin{matrix} K \\ 4 \\ \mathbb{Q} \end{matrix} \begin{matrix} \mathbb{Q} \\ 2 \end{matrix}$

So, eighth problem, give an example of a field extension of a Galois extension, of a field extension K over $\mathbb{Q}$ such that the degree is 4 and K over $\mathbb{Q}$ has no non trivial intermediate fields. So, what I want is an extension of degree 4 of $\mathbb{Q}$ such that there is nothing in between other than K and $\mathbb{Q}$ of course, non trivial means a degree 2 extension here, that cannot happen, so that does not take. So, that is what I want to do.

So, as an simple sanity check, you can check that any such extension has to be, or cannot be Galois let us say, because if it is Galois, the Galois group is either cyclic of order 4 or a Klein 4 group both of which are a subgroup of order 2, normal subgroup. So, you can take the fixed field and that will give you an intermediate field. So, you cannot take a Galois extension.

(Refer Slide Time: 25:40)

Let $f \in \mathbb{Q}[X]$ be an irr quartic st $\text{Gal}(f) = A_4$.
 (See the previous class for an example of such f)

$L = \text{sp fld of } f$ $H = \langle (123) \rangle \subseteq A_4$.
 H is a subgroup of A_4 of order 3.

$L \supseteq L^H \supseteq \mathbb{Q}$

(See the previous class for an example of such f)

$L = \text{sp fld of } f$ $H = \langle (123) \rangle \subseteq A_4$.
 H is a subgroup of A_4 of order 3.

$K = L^H$ claim: $K/\mathbb{Q}$ has no nontrivial int flds

Pr: Let $H \subseteq H' \subseteq A_4$ be subgps

Ex: Then $H = H'$ or $H' = A_4$.

So, the example I will give you now is let f be an irreducible quartic degree 4 irreducible polynomial such that Galois group is A_4 , we in the previous class, we did see such examples. So, previous class for an example of such f , so, we did construct a quartic irreducible polynomial whose Galois group is A_4 . So, let us take K , or I just want to call L , the splitting field of f , and we have $\mathbb{Q}$. Now, let us consider H to be the subgroup generated by these three cycles of A_4 , this is a cyclic subgroup. And H is in fact, a normal sub, H is a subgroup of A_4 of order 3 of course. So, I am going to take its fixed field.

Now, I am going to claim that it cannot have any intermediate fields. So, let me just, I want to just take a look because I do not want to mess up anything. So, here what is the degrees here? Because H is order 3, this is order 3, and because H is index 4, this is degree 4. So, this is going to be my claim. So, claim K over Q has no non trivial intermediate fields. Proof is because L over Q is Galois, we can apply main theorem. So, what we will show is let H be a subgroup, I mean H is given, but let H prime be a subgroup of A_4 contained in A_4 but containing H . So then, this is an exercise, group theory exercise show that H is H prime or H prime is A_4 .

So, there are no proper subgroups of A_4 that properly contain H . So, this is a maximal proper subgroup in some sense. So, by main theorem, the claim follows, this claim follows because if there is any intermediate field that must correspond to a subgroup H prime of A_4 which contains H , but such a thing cannot happen. So basically, the whole problem is to check this exercise which I will let you do. So, now, let me give you an idea of how to do this for arbitrary field extensions.

(Refer Slide Time: 28:46)

So now, 9 problem. So, this is in context of Galois, inverse Galois problem. Remember inverse gamma problem asks, If any finite group can be realized as a Galois group over Q . If you do not insist on the base field Q , we can always do this. So, let G be a finite group show that there exists a Galois extension K over Q , K over, of course, if I prove that that will be solving inverse Galois problem.

So, I want to say there is a Galois extension K over F such that. So, here the point is, I am allowed to choose both K and F depending, after you give me G , inverse Galois problem F has to be Q , only K has to be chosen. So, that makes it much more difficult. In fact, this problem is easy exercise. And that problem is an open problem. So, if you insist on F equal to Q , it is an open problem. But if you are allowed to choose any F you want, it is an easy exercise. And how do we do this?

(Refer Slide Time: 30:24)

Lemma: For every $n \geq 1$, $\exists$ a Galois ext K/F st. $\text{Gal}(K/F) \cong S_n$. 

Pf: $F = \mathbb{Q}(t_1, \dots, t_n)$ (can replace $\mathbb{Q}$ by any field)
 $t_1, \dots, t_n$ are variables.

Pf: $K = \mathbb{Q}(t_1, \dots, t_n)$ (can replace $\mathbb{Q}$ by any field) 
 $t_1, \dots, t_n$ are variables.
 Then S_n acts on K by permuting t_i .
 S_n is a subgroup $\text{Gal}(K/\mathbb{Q})$.

K/F is Galois
 $\text{Gal}(K/F) \cong G$

S_n is a subgroup $\text{Gal}(K/\mathbb{C})$.

$S_n \mid \text{Gal}(K/F)$
 $K^{S_n} = F$

Let $F = K^{S_n}$.

By our earlier results: K/F is Galois with $\text{Gal}(K/F) \cong S_n$.

First, we will show that lemma for every n , there exists a Galois extension K over F , such that $\text{Gal}(K/F)$ is isomorphic to S_n . So again, for over $\mathbb{Q}$, you can do this, this is true, but significantly harder than what I am going to do. So, this requires more work. So, what I do is, you take F to be $\mathbb{Q}$ adjoined some variables, t_1 through t_n . So, I can take, can replace $\mathbb{Q}$ by any field here, but just for concreteness, I will do this. So, this is t_i 's are variables. So, what I do is, so this is a rational function field or $\mathbb{Q}$ in n variables.

So, then, so I am going to take this to be K actually, then S_n acts on K by permuting t_i . So, of course, it fixes $\mathbb{Q}$, but t_i goes to $t_{\sigma(i)}$ via the action of S_n . So, take a permutation and just see where 1 goes to, if 1 goes to 3, t_1 will go to t_3 . So, that means, σ in S_n . So, basically S_n is in a subgroup of $\text{Gal}(K/\mathbb{Q})$. Of course, $\text{Gal}(K/\mathbb{Q})$ is an infinite group, because K is an infinite extension of $\mathbb{Q}$. So, there will be infinitely many elements here, but S_n is a finite subgroup.

So, let F be K^{S_n} . So, the fixed field of S_n . So, you have K , K^{S_n} and it is a triviality by our earlier results K over F is Galois with the Galois group, this is even before we talked about Galois extensions and some of the preliminary results that we did way back in the course. So, this is Galois and Galois group is S_n . In general, if you remember things like this. So, these are from earlier. Now, I want to just give you a brief idea of what F is.

(Refer Slide Time: 33:12)

By our earlier results: K/F is Galois with

In fact: $F = \mathbb{Q}(s_1, s_2, \dots, s_n)$ where s_i are elementary symmetric functions in $t_1, \dots, t_n$

$$s_1 = t_1 + \dots + t_n$$

$$s_2 = t_1 t_2 + t_1 t_3 + \dots = \sum_{i < j} t_i t_j$$

$$s_n = t_1 \cdot t_n$$

In fact:

$$s_1 = t_1 + \dots + t_n$$

$$s_2 = t_1 t_2 + t_1 t_3 + \dots = \sum_{i < j} t_i t_j$$

$$s_n = t_1 \cdot t_n$$

$$f \in F[X]$$

$$K[X] \ni (X-t_1)(X-t_2) \dots (X-t_n) = X^n - s_1 X^{n-1} + s_2 X^{n-2} - \dots + s_n$$

$\in F[X]$

In fact: K is the sp fd of f over F ; roots of f are $t_1, \dots, t_n$.

So, in fact, F is $\mathbb{Q}$ adjoined s_1, s_2 , and s_n where s_i are elementary symmetric functions. So, that is s_1 is in t_1 through t_n , s_1 is actually nothing but small s_1 is nothing but t_1 plus t_n , s_2 is t_1, t_2 plus $t_1 t_3$ and so on. So, this is in fact $t_i t_j$, i less than j . And finally, s_n is the product of all of them. So, basically what I am saying is that if you take X minus t_1 , X minus t_2 , X minus t_n , this is a priori in $K[X]$ is actually in $F[X]$. So, elementary symmetric functions are the coefficients of this, because coefficients of x power n minus 1 will be the sum of this and the constant term will be t_n, t_1 through t_n , so s_n .

So, in fact, K is the, so basically this implies that, let us call this f , f is this polynomial, f is in $F[X]$, because all the coefficients are in capital F . So, k is the splitting field of f over capital F , because the roots of F are t_1 through t_n and of course, these are distinct elements.

(Refer Slide Time: 35:17)

$$[K:F] \leq n! ; \text{ check: } F \subseteq K^{S_n}$$

Because: $\sigma(s_i) = s_i \forall i, \forall \sigma \in S_n$

$$n! \geq \begin{matrix} K \\ | \\ n! \\ | \\ K^{S_n} \\ | \\ F \end{matrix} \Rightarrow F = K^{S_n}$$

$$[K:F] \leq n! ; \text{ check: } F \subseteq K^{S_n}$$

Because: $\sigma(s_i) = s_i \forall i, \forall \sigma \in S_n$

$$n! \geq \begin{matrix} K \\ | \\ n! \\ | \\ K^{S_n} \\ | \\ F \end{matrix} \Rightarrow F = K^{S_n}$$

$$\begin{matrix} \mathbb{Q}(t_1, \dots, t_n) \\ | \\ \mathbb{Q}(s_1, \dots, s_n) \end{matrix} \rightarrow \text{Galois with Galois gp } S_n$$

So, K_w is the splitting field, so the degree of this is at least or at most n factorial, because in general if you have a splitting field of a degree n polynomial the degree is at most n factorial, the factorial of the degree. So, now, what is k power S_n ? So, I claim that f is contained in K power S_n because, this is because σ fixes these are symmetric functions. So, by their very nature, any permutation will fix them because if you permute the sum you are not changing anything.

So, if so, we have K , K power S_n and F here. So, this is less than or equal to n factorial and this is equal to n factorial. This means F equals K power S_n . So, the desired Galois extension of Galois group S_n is Q adjoined t_1 through t_n over Q adjoined S_1 through S_n is Galois with Galois group S_n . So, this can be done for any n . Now, let us prove the solution of the, let us give the solution of the problem.

(Refer Slide Time: 36:54)

$F = \mathbb{Q}(S_1, \dots, S_n)$

By Cayley's thm: every finite gp G is iso to a subgroup of S_n .

$G \hookrightarrow S_n$

$\left. \begin{array}{c} K \\ K^G \\ K \\ F \end{array} \right\} \rightarrow \text{this is a Galois extn with Galois gp } G$

So, by Sylow theorem, by Cayley's theorem, every finite group is isomorphic to a subgroup of S_n . So, now, we are done. So, we first take K and you take F . So, G is isomorphic to so as subgroup of S_n . So, we will simply take K power G . So, this is the Galois extension, this is a Galois extension with Galois group G . So, this solves the problem. So, problem asks you to show that there is a Galois extension with Galois groups to be any given finite group and you are, you have done that, but the important thing is of course, you are allowed to choose both the top and the base fields, if the base field is fixed to be Q , there is no solution to this problem, this is an open problem called inverse Galois problem.

- (10) Fix $n \geq 1$. Give an example of an ext K/F st $[K:F]=n$
and K/F has no nontrivial int. fds.

Earlier we did
 $n=4$
 $F=\mathbb{Q}$

Soln: K
Galois with $\text{Gal}(K/F) = S_n$
 F $H = \{ \sigma \in S_n \mid \sigma(n) = n \} \leq S_n$
 H is a Subgrp of S_n isomorphic to S_{n-1} .

and K/F has no nontrivial int. fds.

$n=4$
 $F=\mathbb{Q}$

Soln: K
Galois with $\text{Gal}(K/F) = S_n$
 $H = \{ \sigma \in S_n \mid \sigma(n) = n \} \leq S_n$
 H is a Subgrp of S_n isomorphic to S_{n-1} .
 $L := K^H$
 L/F has the desired property.

no proper
int. fds

Pf: check $H \leq H' \leq S_n \Rightarrow H = H'$ on $S_n = H'$.

subgrps
If $\sigma \in H', \sigma \notin H$, show that H' contains all

$$L = K^H / F$$

H is a Subg of S_n isomorphic to S_{n-1} .

Claim: L/F has the desired property.

Pf: Check: $H \subseteq H' \subseteq S_n \Rightarrow H = H'$ on $S_n = H'$.

$\{ \sigma \in H', \sigma \notin H, \text{ show that } H' \text{ contains all 2-cycles} \}$

Now, last problem I want to do in this class is for every n , integer n give an example of an extension K over F such that the degree of the extension is n and K over F has no proper or non trivial intermediate fields. So, now, this is just like earlier we did n equal to 4 and F equal to Q in fact, but in general we have to allow F to be arbitrary. So, what do we do?

Solution, I want to quickly wrap this up. So, you take K and F Galois with Galois group S_n . Now, what do we do? What we do is the following. Let us take H to be all elements of S_n , which fix let us say n . So, this is a subgroup of S_n . So, H is a subgroup of S_n isomorphic to S_{n-1} because it interchanges the first $n-1$ indices does nothing to the n th, last index. So, this is what we have. So, now, what we do?

As you can guess, you take K^H . So, K^H is a Galois extension of F with Galois group H which has $(n-1)!$ elements, the whole extension is $n!$, so this is n . So, claim is L/F has the desired property. The proof is very easy, this is just like in the n equal to 4 case. All you need to do is that S_{n-1} the way we have defined it here is a maximal proper subgroup.

So, which I will let you do this, this is a simple group theory statement. So, if you have H is contained in H' prime is contained in S_n subgroups, then H equals H' or S_n equals H' . So, this is a statement one can show basically show that if σ belongs to H' and σ is not in H that means it is not equal to H . Show that H' contains all two cycles. So, this came up earlier when we showed that S_n is generated by a two cycle and an n cycle.

So, similar to that kind of argument you show this. So, the claim will then follow, so that any proper intermediate field must correspond to a subgroup containing capital H, but any subgroup containing capital H, is either H in which case the intermediate field is this or S_n in which case intermediate field is F. So, there is nothing in between these two, no proper intermediate fields or no nontrivial intermediate fields. So, that settles the problem with constructing degree and extensions with no proper intermediate fields.

(Refer Slide Time: 42:07)

⑩ Fix $n \geq 1$. Give an example of an ext K/F st $[K:F]=n$
 and K/F has no nontrivial int. fds.
 Earlier we did $n=4$
 $F=\mathbb{Q}$

Soln: K
 Galois with $\text{Gal}(K/F) = S_n$
 $H = \{ \sigma \in S_n \mid \sigma(n) = n \} \leq S_n$
 $|H| = (n-1)!$
 $L := K^H$
 L/F is a subgrp of S_n isomorphic to S_{n-1} .
 Claim: L/F has the desired property.

Note: Such an extn can't be Galois (n is not prime)

no prime
fals

And again, as I noted there note, such an extension cannot be Galois except in some trivial cases like n equal to prime, so, let us assume n is not prime. Otherwise there will be a prime divisor and there will be a proper subgroup, so there will be a proper intermediate field. So, I will write unless n is prime.

Of course in which case the Galois extension will not have a trivial, will not have a proper intermediate fields because a group of order p cannot have proper nontrivial subgroups. So, I think that is, I do have 1 or 2 problems but let me stop here. In the next class we will do a couple of more problems and that will end the course. Thank you.
