$\sigma': K \rightarrow L$ which extends σ .
 That is: $\sigma'|_F = \sigma$.
 $a \in F \Rightarrow \sigma'(a) = \sigma(a) \in L$ ✓

The proof uses Ext thm I and Zorn's lemma.

Cor: (1) Let F be a field and let $f \in F[X]$. Then any two splitting fields of f over F are F -isomorphic.

Exercise (2) Let L be a field. Any two algebraic closures of F are F -isomorphic.

Welcome back. In the course so far, we reviewed the required material from groups, rings, fields and I am ready to start Galva Theory. But before that let me do a couple of problem sessions so that you understand how to solve problems and also recall some important concepts from field theory. So, I will mostly stick to field theory problems. So, let me start with the problem that I gave at the end of the last video, this exercise that I have written here. So, you recall that we proved a couple of extension theorems and we talked about algebraically closed fields. So, the first exercise today.

(Refer Slide Time: 00:56)

Problem Session

- 1) Let F be a field and let $f \in F[x]$. Then any two splitting fields of f over F are isomorphic as field extensions of F .
(F -isomorphic)

So, today our problem sessions, so the first problem is let F be a field and let small f be a polynomial over that field, then any 2 splitting fields of f over F are isomorphic. So, I am not going to isomorphism as S field extensions of F not just abstractly isomorphic S fields but as field extensions of F that is they are F isomorphic

(Refer Slide Time: 01:50)

Soln: Let K, L be two splitting fields of f over F .

Let $\alpha \in K$ be a root of f .
Extension theorem applies here because L contains a root of f .
(take $\sigma: K \hookrightarrow L$ inclusion.)

We get (after one step) an F -iso $F(\alpha) \rightarrow F(\beta)$ where β is a root of the irr poly of f over F st. $\beta \in L$.

Diagram 1: A field extension diagram showing F at the bottom, with K and L above it. A diagonal arrow labeled σ points from F to L .

Diagram 2: A field extension diagram showing F at the bottom, with $K(\alpha)$ and $K(\beta)$ above it. A diagonal arrow points from F to $K(\beta)$. Above $K(\alpha)$ is K , and above $K(\beta)$ is L . A diagonal arrow points from K to L .

Diagram 3: A field extension diagram showing F at the bottom, with $K(\alpha)$ and $K(\beta)$ above it. A diagonal arrow points from F to $K(\beta)$. Above $K(\alpha)$ is $K(\alpha_2)$, and above $K(\beta)$ is $K(\beta_2)$. A diagonal arrow points from $K(\alpha_2)$ to $K(\beta_2)$.

Extension Theorems :

Extension theorem I : Let K/F be an ext of fields.
 Let $\alpha \in K$ be alg/F; let $f \in F[x]$ be the irr poly of α/F .
 Let L be a field with a field hom $\sigma : F \rightarrow L$.
 Suppose $\sigma(f)$ has a root in L ; say β .
 Then there exists a field homomorphism
 $\sigma' : F(\alpha) \rightarrow L$ which extends σ .

$$\begin{aligned} \sigma : F &\rightarrow L \\ \sigma : F[x] &\rightarrow L[x] \\ x &\mapsto x \\ F \ni a &\mapsto \sigma(a) \\ \sigma(a_n x^n + \dots + a_1 x + a_0) &= \sigma(a_n) x^n + \dots + \sigma(a_1) x + \sigma(a_0) \end{aligned}$$

So, I am not going to do the full details of this because it is essentially an immediate consequence of the extension theorems that we proved. So, let me set it up and I need some details you can provide yourselves. So, let K and L be 2 splitting fields of small f or big F . So, here what we have is this. They are both extensions of F . So, by definition a splitting field is an extension of F where the polynomial splits completely and those extensions are generated by the roots. So, now let α be in K , be a root of f . It has all the roots so it has, let us take 1 of them. So, what we have is actually a picture like this.

Now if you recall what the first extension theorem says, first extension theorem applies here and gives a map like this which extends the map from K to L because the reason it extends here is because L contains a root of f . If you go back to the first extension theorem, you have some arbitrary field extension on algebraic element in the bigger field. You have an irreducible polynomial.

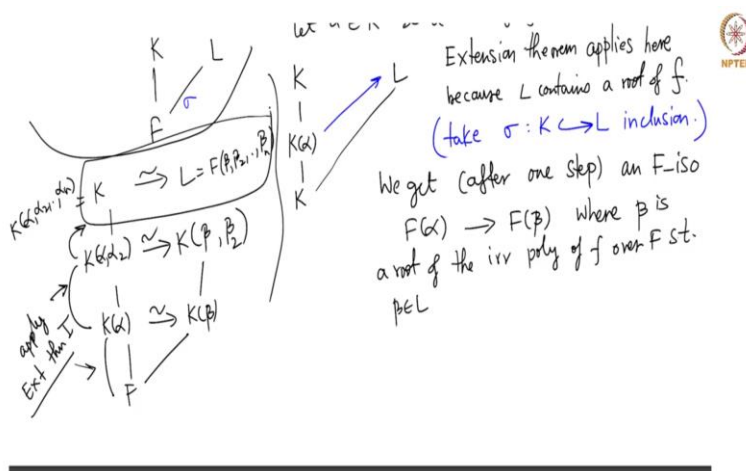

So, the given polynomial in our problem may not be reducible but we can take the irreducible polynomial of α which will be a root of f . So, those are details that you can fill in. And in general, we actually worked with an arbitrary field L and the homomorphism such that σ has a root in β . So, here I am going to take σ to be identity. So take, I mean σ to be the inclusion. So, σ is just this, σ exists already because F is a subfield of L .

So, with that, what you have is an extension. So, you can extend it and then if you go back to the proof or rather the explanation that I gave without really proving it in detail is that this extension here takes f alpha to f beta. So, f prime is the image in general. But f prime is f here.

So, f alpha, so we get basically after 1 step, an isomorphism, an F isomorphism f alpha to f beta where beta is a root of the irreducible polynomial of f over capital F such that beta is in L . So, remember F may not be reducible. So, f may have factor as irreducible factors like this and this may be the irreducible polynomial of alpha over f let us say. Then because f splits completely in L , so it has f_1 . So, f_1 also has a root and you apply technically you apply the extension theorem to f_1 alpha and capital L .

So, then what you get is K alpha as isomorphic to K beta over F and then you keep going. So, K alpha, alpha 1, this alpha can be thought of as alpha 1. So, then you get an isomorphism from K beta, beta comma beta 2. So, this is an extension and then you keep going. And you keep going. So, I am a bit fast here. But ultimately what you can do is this is isomorphism from this to this because K is nothing but K alpha, alpha 2, alpha n . L is nothing but f beta, beta 2, beta n .

(Refer Slide Time: 06:40)

So, you can also check that these roots, number of roots are the same as part of this process. First you show that this is an isomorphism then you apply extension theorem again. So, apply extension theorem to this, extension theorem again to this. Here, we applied it and gotten this isomorphism, apply it again, apply it again and so on to get this. So, this is the statement that any

2 splitting fields are isomorphic. So, I am just going over this fast because this is something that you can think about. You will understand more if you actually think and supply all the missing details.

(Refer Slide Time: 07:16)

2) Let F be a field. Any two algebraic closures of F are F -isomorphic.

Soln: Let K, L be 2 alg closures of F

Apply Ext Thm II to alg ext K/F and $F \hookrightarrow L$:

Extension theorem II: Let K/F be an alg extension,

and let L be an alg closed field with a field hom $\sigma: F \rightarrow L$. Then there exists a field homom $\sigma': K \rightarrow L$ which extends σ .

That is: $\sigma'|_F = \sigma$.

$a \in F \Rightarrow \sigma'(a) = \sigma(a) \in L$ ✓

These ext theorems are useful to us later

So, now let me do the second problem that I gave last time which is also an immediate consequence of the extension theorem. So, let f be any field, any 2 algebraic closures of f are F isomorphic. So, what I am saying is that, so again I will, I would not go to details. But let maybe not the full details I mean. Let K and L be 2 algebraic closures of F . So, we have K and L and they are both algebraic closures of F . Our goal is to show that there is an isomorphism over the

field f so that means, that means there is an isomorphism which fixes f point wise, that is important for us. So, this is also easy.

Because apply now, extension theorem 2. And if you recall what is extension theorem 2 say, if you have any algebraic extension and a algebraically closed field L of F , then there exists a map from K to L which extends σ . So, here of course σ is inclusion map. So, basically apply this to algebraic extension K over F and the inclusion of F in L . So, this is σ .

(Refer Slide Time: 08:57)

for which extends σ

pf: σ' is an isomorphism
 σ' is injective ✓
 only to show: σ' is surjective

Let $\alpha \in L$. Then α is alg/F $\Rightarrow \alpha$ is alg/ K' .
 K alg closed $\Rightarrow K'$ is alg closed ✓
 $\Rightarrow \deg \alpha$ over $K' = 1$.
 $\Rightarrow \alpha \in K'$

$\therefore L \subseteq K' \subseteq L \Rightarrow L = K'$ and σ is an iso

So, then by the extension theorem, it gives us a map. This remember is the map, is the inclusion map. So, it is not an arbitrary I mean, it is actually an inclusion of F in L . F sits inside L as a subfield then by the extension theorem there is a map like this, σ' I think I called. So, there exists σ' which extends σ . So, that is the conclusion of the extension theorem.

Now I claim σ' is the desired isomorphism, F isomorphism. The proof is clear. First of all σ' is an F homomorphism because it extends the σ and σ is an inclusion of F in L . So, any element of F goes to itself. So, σ' fixes F . This is, σ' is injective or 1, 1 in other words. This is because any field homomorphism is so, so it is an injective map only to show σ' is surjective. If it a surjective map from K to L , it is also an injective map so it is an isomorphism.

And this is clear because let us take any arbitrary element α in L . So, what we have is, of course α is algebraic over F because remember, algebraic closure is an algebraically closed field which is an algebraic extension of the base field. So, L is algebraic over F . So, that means α is algebraic over F that means α is algebraic over K . So, let me just set up some more notation here.

So, we have F, K, σ . Let us say it goes to K' which is in L , just sticking to the notation that I normally do. I will denote it like this. So, K' is the image of σ . So, K' is equal to $\sigma(K)$. So, we want $K' = L$. So, that is my goal but a priori maybe K' is a smaller field than L . It is simply the image of the map σ that exists by the extension theorem.

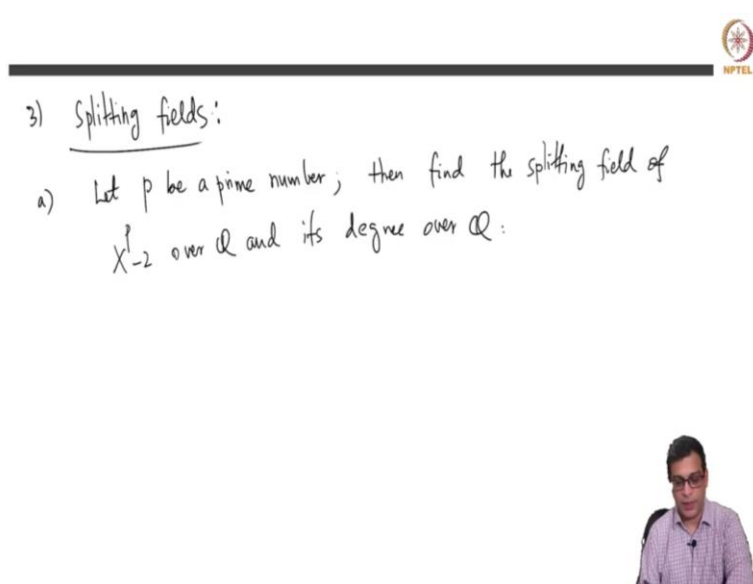

So, I am picking α here, α is algebraic over F rather than α is algebraic over F . So, I should really say α as an element is algebraic over K' because if α is algebraic over F , it is it has it satisfies the polynomial $f(x)$ in $F[x]$. That polynomial belongs to $K'[x]$ also. So, α is algebraic over K' . Now we use another set of implications, so K is algebraically closed. So, so far we have used that L is algebraic over F because that is we have also used L is algebraically closed in order to apply the extension theorem.

Now we are using L is algebraic over F here. We have also already used that K is algebraic over F in order to use extension theorem. Now we are going to use K is algebraically closed. So, both facts for L namely that it is algebraically closed and it is algebra over F are used for L as well as for K . So, you remove any of those properties, this proof will not work. So, K is algebraically closed implies K' is algebraically closed. This is a fairly easy exercise. Algebraic closure is preserved by a field isomorphism.

Remember σ is an isomorphism onto K' . So, if every polynomial non-constant polynomial in K has a root, then every non-constant polynomial K' has a root, so that is easy. K' is algebraically closed and that means degree of α over K' is 1 because that is the meaning of algebraically closed field. So, α is algebraic over K' , so it satisfies a polynomial of K' . Take the irreducible polynomial of α over K' . But the only reducible polynomial of K' , over K' are linear polynomial. So, that means degree of K' , degree of α over K' is 1 that means α is in K' .

So, we have taken an arbitrary α in L and concluded that it is in K . So, that means L is in K prime, K prime is of course in L . So, that means L equals K prime and σ is an isomorphism, so that completes the solution. So, this is the proof that any two algebraically algebraic closures are F isomorphic. So, the proof is not that important. We have done it so that you understand how to go about using extension theorem and the statements will be used later. So, typically we often talk about these splitting fields of a polynomial or the algebraic closure of a field just to when there is no danger of confusing the two fields. As far as f extensions are concerned they are isomorphic.

(Refer Slide Time: 14:50)

3) Splitting fields:

a) Let p be a prime number; then find the splitting field of $X^p - 2$ over \mathbb{Q} and its degree over \mathbb{Q} :

So, now let me do a third exercise, third exercise on splitting fields. So, I am going to just give you a few examples of how to compute splitting fields. Again these are things that you may have studied in you in your algebra field theory course but I want to do, just do and hands on examples so that you are comfortable with the kind of calculations that we will do later. So, let me start with some simple example, so let p be a prime number, then find the splitting field of X power p minus 2 over \mathbb{Q} and its degree. So, find the splitting field and its degree over \mathbb{Q} . So, this is the problem.

(Refer Slide Time: 15:53)

$X^p - 2$

Soln: $K = \text{sp. fld of } X^p - 2 \text{ over } \mathbb{Q}.$

Roots: $\sqrt[p]{2} \in \mathbb{R}$ real p -th root of 2.

Let ζ_p be a primitive p th root of unity ($\zeta_p \in \mathbb{C}$)

The roots of $X^p - 2$ in \mathbb{C} are: $\boxed{\zeta_p^i \sqrt[p]{2}, 0 \leq i \leq p-1}$

$\therefore K = \mathbb{Q}(\sqrt[p]{2}, \zeta_p)$

The first point I want to emphasize is what is a splitting field? So, let, we will denote the K by K , denote the splitting field by K . So, I am going to shorten it like this. So, think about this for a minute. What are the roots of this polynomial? Roots if you think about it, first of all you can take the p th root of 2, take the real p th root of 2. P is a positive numbers so there is a real p th root of 2 in \mathbb{R} , so real number. And let ζ_p be a primitive, p th root of unity. So, this is of course in complex numbers, it is typically not. In fact P is a prime numbers so it, unless it is 2 it will not be in real numbers. So, let it be the a primitive. There could be several primitive p th roots.

So, let it be a primitive p th root of unity. So, then the roots of $X^p - 2$ in \mathbb{C} are. So, remember there is a God given algebraically closed field that contains \mathbb{Q} . So, we can always take root there and then generate the splitting field by taking the roots, the field generated by those. So, the roots of $X^p - 2$ you will see \mathbb{R} . You can easily prove this. There you have, so these are the p roots which has p roots it is a degree p polynomial. So, it will have p roots there given by $\zeta_p^i \sqrt[p]{2}$ times p root 2 p th root of 2. So, you get p th root of 2 for i equal to 0, then $\zeta_p \sqrt[p]{2}$ p th root of 2, $\zeta_p^2 \sqrt[p]{2}$ p th root of 2 and so on. So, the splitting field is \mathbb{Q} adjoined, clearly if you think about this, I can just take this.

(Refer Slide Time: 18:02)

The roots of $X^p - 2$ in \mathbb{C} are: $\zeta_p \sqrt[p]{2}, \dots, \zeta_p^{p-1} \sqrt[p]{2}$

$\therefore K = \mathbb{Q}(\sqrt[p]{2}, \zeta_p)$

$\mathbb{Q} \xrightarrow{?} K$

Reason: $X^p - 2$ is irr / \mathbb{Q}

Eisenstein criterion

What is the irr poly of ζ_p over \mathbb{Q} ? ζ_p is a root of $X^{p-1} + X^{p-2} + \dots + X + 1$

$X^p - 1 = (X-1)(X^{p-1} + X^{p-2} + \dots + X + 1)$

recall from an earlier video $r+1$

find n

p divides n

p-1 divides n

p prime is important here

Because once I have these 2, I have all the other roots because I can take powers of this and remember these two must be included if either you remove any of them, it will not be a splitting field because if you only put pth root of 2 you cannot get other roots. If you only put the pth root of unity, you would not get pth root of 2. So, now what is the degree of this? So, now in order to find this, I am going to use the multiplicative property of the field ex degree of the field extensions and carefully break up this extension like this.

So, now the first point I want to emphasize is there are 2 subfields here, so these are both subfields and we do know what are the extension degrees here. I claim that this is p and this is p minus 1. Why is this? The reason for this and this is first point is $x^p - 2$ is irreducible, is over \mathbb{Q} , irreducible over \mathbb{Q} . This is simply by Eisenstein criteria. Remember $x^p - 2$ is a polynomial that pth root of 2 satisfies and $x^p - 2$ is irreducible, so this degree must be p. So, that is ok.

On the other hand what is the irreducible polynomial of this? This is the primitive extension as it is called that means it is generated by a single element. We will talk about primitive extensions in detail later. So, the degree of this extension will be simply the degree of the irreducible polynomial of ζ_p . But what is that? So, ζ_p certainly satisfies, this polynomial. So, ζ_p is a root. Let me write it more precisely. It is a root of this, but of course that is not irreducible right because $x^p - 1$ does factor like this.

But this is irreducible right so recall from the recall from an earlier video. It does not look like you can apply Eisenstein here, directly certainly you cannot apply, but do the change of variable x to x plus 1 then you can apply. And then here is where the fact that p is prime is important. It is not going to be true if p is not prime. So, p is prime is important here. That is the only place where we use p prime. So, that means this is p minus 1 because irreducible polynomial is ζ^p over \mathbb{Q} has degree p minus 1. So, this is p minus 1 that means whatever this number is. So, we are interested in finding this number n . So, the question is find n .

So, what we know is that p divides n and also p minus 1 divides n . p divides n and p minus 1 divides n because whatever I mean, n is equal to p times this number, n is also equal to p minus 1 times this number. But of course there are lots of numbers that p and p minus 1 divide. But I claim that it must be p times p minus 1 because now let us look at what can be the degree of, let us say this.

(Refer Slide Time: 22:05)

$$\left\{ \begin{array}{l} [K: \mathbb{Q}(\zeta_p)] \leq p \\ [K: \mathbb{Q}(\sqrt[2]{p})] \leq p-1 \end{array} \right\}$$

Both of these must be equalities because p and $p-1$ are coprime ✓

$\therefore [K: \mathbb{Q}] = p(p-1)$ ✓

this is because the irr poly of $\sqrt[2]{p}$ over $\mathbb{Q}(\zeta_p)$ has deg $\leq p-1$.

I claim that that is at most p . So, this degree is less than or equal to p . And similarly this degree is less than equal to p minus 1. So, let me show it. I cannot show it here but, so this degree is less than equal to p minus 1, this degree is less than equal to p this is because these are both primitive extensions, the A is the primitive extension of this because it is generated over this field by just ζ^p . This is also a primitive extension because this K or $\mathbb{Q}(\zeta^p)$ is generated by p th root of 2.

The irreducible polynomial let us say of p th root of 2 over \mathbb{Q} has degree less than p . This is because irreducible polynomial of x power p p th root of 2 over \mathbb{Q} itself is degree p . So, the irreducible polynomial over a bigger field it can possibly split so it cannot be higher degree. So, it is at most p . So, similarly this is at most p minus 1, this is at most p but now you have a this. So, let us focus on this direction. This number is at most p , the product is divisible by p so that number in both cases, both of these must be equalities because p and p minus 1 are co-prime.

You cannot have a smaller number than p here and still have the product with p minus 1 to be divisible by p . So, they are both co-prime. So, that is not possible. That means, so this solves the problem. So, the splitting field is degree p times p minus 1. So, now let us do why p , I mean the proof does not work with p not prime but in fact the statement is also wrong with p not prime.

(Refer Slide Time: 24:38)

mod22lec08 - Problem Session 1

(b) Find the splitting field of $X^4 + 1$ over \mathbb{Q} and its degree over \mathbb{Q}

Soln: Roots of $X^4 + 1$: primitive 8th roots of unity.

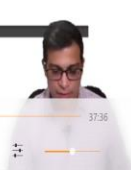

$$X^4 + 1 = 0 \Rightarrow X^4 = -1 \Rightarrow X^8 = 1 \Rightarrow X \text{ is an 8th root of unity.}$$

Since $X^4 = -1$ ($X^4 \neq 1$), X can't be a 4th root, 2nd, 1st root of unity.

27:11 37:36

⏮ ⏪ ⏸ ⏩ ⏭ 🔍

Soln: Roots of $X^4 + 1$: primitive 8th roots of unity.

$\alpha^4 + 1 = 0 \Rightarrow \alpha^4 = -1 \Rightarrow \alpha^8 = 1 \Rightarrow \alpha$ is an 8th root of unity.

Since $\alpha^4 = -1$ ($\alpha^4 \neq 1$), α can't be a 4th root, 2nd, 1st root of unity.

What a primitive 8th root of unity: $\cos \frac{2\pi}{8} + i \sin \frac{2\pi}{8}$

$\{ e^{\frac{2\pi i n}{8}} \mid n=0, \dots, 7 \}$ $= \cos \frac{\pi}{4} + i \sin \frac{\pi}{4}$

$= \frac{1}{\sqrt{2}} + i \frac{1}{\sqrt{2}}$

8th roots of unity

So, the second example is find, so I will come to the second example but maybe first do some other things which come up in 4. So, for example find the splitting field of x power 4 minus 4 minus, so I think this I mentioned in the video where I recalled splitting fields but let me I am going to use this. So, let me just recall the splitting fields. So, x power 4 minus 1, so this actually let me do x power 4 plus 1. So, because that is going to be the polynomial that I will need it for later. So, this if you take what are the roots of.

So, I claim that roots of x power 4 plus 1 are precisely primitive 8th roots of unity. So, these are primitive 8th roots of unity. This is because if α power 4 plus 1 equals 0, then α power 4 equals minus 1 that means α power 8 is 1. So, that means α is in eighth root of unity. But if it is not a primitive 8th root of unity, for example i is an i th root of eighth root of unity but i power 4 is 1, so i power 4 plus 1 is not 0. So since, so α power 4 is equal to minus 1, α power 4 is not equal to 1. So, α cannot be a root of unity, cannot be a fourth root.

So, any root eighth root of unity is either a fourth root of unity or a second root of unity or first root of unity. It cannot be a fourth root, second root or first root of unity. So, if α , α power 8 is 1, then either α is 1 or α square is 1 or α 4 is 1 or α power 8 is 1. So, it cannot be any of those.

So, α is a primitive eighth root of unity. What are primitive eighth roots of unity? What is a eighth primitive root of unity? So, let me write, this is precisely cosine 2π by 8, plus i sine 2π by 8. So, in general all the root eighth roots of unity are given by, these are the eighth roots of

unity. You can take i equal to 1 that will give you a n equal to 1 that will give you a primitive eighth root of unity but this is cosine π by 4 plus i sine π by 4. This is 1 by root 2 plus i times 1 by root 2. Now if you think about this. So, this is what I want to say for now. So, the primitive 8th root of unity has this.

(Refer Slide Time: 28:45)

what a primitive 8th root of unity: $\omega = \frac{1}{\sqrt{2}} + i \frac{1}{\sqrt{2}}$

$\{e^{2\pi i n/8} \mid n=0,1,3,5,7\}$ NPTEL

$= \cos \frac{\pi}{4} + i \sin \frac{\pi}{4}$

$= \frac{1}{\sqrt{2}} + i \frac{1}{\sqrt{2}}$

$K = \text{Sp fld of } X^4 + 1 \text{ over } \mathbb{Q}.$

So: $\frac{1}{\sqrt{2}} + i \frac{1}{\sqrt{2}} \in K$

So, I have to add, so if let K be the splitting field of $x^4 + 1$ over \mathbb{Q} . So, what we have now shown is that. It becomes what we have shown is that 1 by root 2 plus i times 1 by root 2 is in K . So, 1 by root 2 plus i sine, 1 by root 2 plus i times 1 by root 2 is in K .

(Refer Slide Time: 29:12)

$$K = \text{Sp fld of } x^4 + 1 \text{ over } \mathbb{Q}.$$

So: $\frac{1}{\sqrt{2}} + i\frac{1}{\sqrt{2}} \in K$. Other roots of $x^4 + 1$ are $\left\{ \pm \frac{1}{\sqrt{2}} \pm i\frac{1}{\sqrt{2}} \right\}$ four of them

$$\begin{aligned} &\frac{1}{\sqrt{2}} + i\frac{1}{\sqrt{2}} \\ &\frac{1}{\sqrt{2}} - i\frac{1}{\sqrt{2}} \\ &-\frac{1}{\sqrt{2}} + i\frac{1}{\sqrt{2}} \\ &-\frac{1}{\sqrt{2}} - i\frac{1}{\sqrt{2}} \end{aligned}$$

$$\therefore K = \mathbb{Q}\left(\pm \frac{1}{\sqrt{2}}\right)$$

So, I claim that other roots, other roots of x power 4 plus 1 are. So, one can check easily, these are going to be you can put so I should have really written it like this. So, these are the 4 roots. So, you can take 1 by root 2 with plus sign or minus sign, i times 1 by 2 with plus sign or minus sign. So, there are 4 of them. So, you can immediately conclude that K is equal to \mathbb{Q} joined, plus minus 1 by root 2. So, I mean, you understand what I mean here. So, 1 is, the other is this so, these are the roots. If you, clearly you can check that their 4th power will be minus 1.

(Refer Slide Time: 30:18)

$$\therefore K = \mathbb{Q}\left(\pm \frac{1}{\sqrt{2}} \pm i\frac{1}{\sqrt{2}}\right) = \mathbb{Q}(\sqrt{2}, i) \quad \text{sp fld}$$

$\xrightarrow{\text{exercise}} \begin{matrix} 12 \\ \mathbb{Q}(\sqrt{2}) \\ 12 \\ \mathbb{Q}_R \end{matrix} \leq 2; \text{ but } \mathbb{Q}(\sqrt{2}) \subseteq \mathbb{R} \quad i \notin \mathbb{R} \quad \therefore \mathbb{Q}(\sqrt{2}) \neq \mathbb{Q}(\sqrt{2}, i)$

(c) $x^8 - 2$: roots of this over \mathbb{Q} : $\sqrt[8]{2}, \zeta_8 \sqrt[8]{2}, \zeta_8^2 \sqrt[8]{2}, \dots, \zeta_8^7 \sqrt[8]{2}$

ζ_8 : a primitive 8th root of unity.

$\therefore K = \mathbb{Q}(\zeta_8, \sqrt[8]{2})$

| ??

So, these are the roots. But then if you think about this, both $\sqrt{2}$ and $i\sqrt{2}$ must be there because you can, for example add the first $\sqrt{2}$ here that gives you i^2 times i times $\sqrt{2}$, so $-\sqrt{2}$. So, you can play with these things and conclude that both $\sqrt{2}$ and $i\sqrt{2}$ are there. Once $\sqrt{2}$ and $i\sqrt{2}$ are there all of them are there. So, this is a little exercise for you which you can easily do by manipulating these elements. So, that means what is the degree now? This is the splitting field and what is the degree of Q ?

Of course, this will you can compute this by doing first Q to Q . So, this is 2 because $x^2 - 2$ is the irreducible polynomial. This is also true because i satisfies a degree 2 polynomial of Q . So, it can be at most 2. So, you first note that this is at most 2 but then $Q(\sqrt{2})$ is in R , i is not in R . So, this cannot be equal. So, $Q(\sqrt{2})$ cannot be equal to $Q(\sqrt{2}, i)$. So, this is at least 2 but at the same time it is at most 2. So, it cannot be, it has to be 2.

So, that means K over Q is 4. So, that is the solution to this and the final thing that I want to do just very quickly C is $x^{p^2} - 2$, just to compare this with $x^p - 2$, which we discussed earlier. The degree is $p^2 - 1$ so if the same result is true here it will be $8^2 - 1 = 63$. But it is not so as we will see. What are the roots of this? Roots of this over Q are just going by the same argument as earlier. So, there are 8 roots. This much is true. I mean, you have eighth root of 2, this is a real number and then you take ζ_8 times eighth root of 2 that square is also that eighth power is also 2. So, this is clear? So, my notation is always this is a primitive eighth root of unity.

So, again as before, K must be equal to $Q(\zeta_8 \sqrt[8]{2})$. Now the question is, what is this degree? I claim that this degree is 16. That is because we are going to break this up into a tower like this. This is 2, this is 8 because what is irreducible pol sorry this sign take eighth root of 2. What is irreducible polynomial of eighth root 2 over Q ? That is just $x^8 - 2$ and this is irreducible by Eisenstein's style. So, the question now boils down to what is this? What is this degree? Now ζ_8 over Q has degree 4 as we saw earlier. So, K is of course $\zeta_8 \sqrt[8]{2}$. So, this is at most 4. So, you already see that this cannot be 63. So, this is at least at most 32.

(Refer Slide Time: 34:29)

(16) $L = \mathbb{Q}(\zeta_8)$
 $/8$ because $x^8 - 2$ is irr by Eisenstein
 \mathbb{Q}

Recall: $\zeta_8 = \frac{1}{\sqrt{2}} + \frac{i}{\sqrt{2}}$; $\zeta_8 \in L \Rightarrow \sqrt{2} \in L \Rightarrow \zeta_8 \in L(i)$
 $\Rightarrow K \subseteq L(i)$
 $L \subseteq \mathbb{R}, K \not\subseteq \mathbb{R} \Rightarrow L \neq K$

In conclusion: $L(i) = K$. So
 $[K:\mathbb{Q}] = [K:L][L:\mathbb{Q}] = 2 \cdot 8 = 16$

But in fact I claim that this is 2. Why is that? So, now this is I am going to quickly wrap this up because I have already spent too much time on this video. So, let me wrap this up by saying that Q. So, if you call K, so let us say I call this L. So, I call this L. So, basically, I claim that L is K , so L is K . So, what is the proof of this claim here? So, L is K . Why is that? Zeta 8 as we agreed is 1 by root 2 . 1 choice of, 1 choice for primitive eighth root is this. So, zeta 8 is this but so recall this. But we already know that eighth root of 2 is in L that means square root of 2 is in L because eighth root of 2 power 4 is square root of L .

That means zeta 8 is in L adjoined i right because if you adjoin i , root 2 is already in L . So, then zeta 8 can be you can describe zeta 8 as a polynomial in i with coefficients in L , exactly this way. So, zeta 8 is in L that means K is contained in L but note that as before L is contained in \mathbb{R} , K is not contained in \mathbb{R} , this means L is not equal to K . So, together this imply that. So, in conclusion L is K .

So, K colon Q is K colon L times L colon Q . K colon L is 2 because K is L and L colon Q is 8 so that is 16 . So, all I am saying is this is 8 , this is 2 . So, this is 16 . So, I am sorry that I went very fast over the last part of this problem but I hope this gave you an idea of how to use various results that we have recalled and compute the degrees of splitting field extensions. In the theory field in the Galva theory course, we are going to further analyze this splitting fields. We know

now how to compute the degrees but we are going to talk about automorphisms of K which fix Q . So, that is the goal for us in the rest of the course. Thank you.
