Fourier Series
Lecture – 48
Complex Form of Fourier series

So, we have seen how a periodic function with period 2π can be written as a Fourier series in terms of sines and cosines. And we have also looked at the Dirichlet conditions for convergence of such a function.

So, in this lecture we will show that there is an equivalent exponentials approach right. So, instead of sines and cosines we could express a periodic function in terms of exponentials, right. So, the 2 are completely equivalent, but in some contexts it is more convenient to work with this exponential form that we will lay down in this lecture right.

(Refer Slide Time: 01:00)

Complex Form of Fourier Series

The Fourier series can also be written in terms of complex exponentials:

$$f(x) = c_0 + c_1 e^{ix} + c_{-1} e^{-ix} + c_2 e^{2ix} + c_{-2} e^{-2ix} + \dots,$$
$$= \sum_{n=-\infty}^{\infty} c_n e^{inx}$$

To find the coefficients in this expansion, let us work out the integral:

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx} dx$$

We have:

So, you are given a periodic function with period 2π . So, we are going to write this f of x as c_0 plus c_1 plus e^{ix} plus c_{-1} e^{-ix} plus c_2 e^{2ix} plus c_{-2} e^{-2ix} so on, right. So, you have also these you know now you allow for this index to take negative values as well, right.

So, in other words we are writing this as a summation where n goes now takes all integer values from minus infinity to plus infinity $c_n e^{inx}$, right. So, to find these coefficients c_n right so, let us work this integral on right. So, you are doing this integral $\frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx} dx$.

(Refer Slide Time: 01:56)

We have:

$$\begin{aligned} & \frac{1}{2\pi} \int_{-\pi}^{\pi} \sum_{m=-\infty}^{\infty} c_m e^{imx} e^{-inx} dx \\ &= \sum_{m=-\infty}^{\infty} c_m \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{i(m-n)x} dx \\ &= \sum_{m=-\infty}^{\infty} c_m \delta_{mn} = c_n. \end{aligned}$$

The Fourier coefficients are thus given by

$$c_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx} dx.$$

So, now we have $\frac{1}{2\pi} \int_{-\pi}^{\pi} \sum_{m=-\infty}^{\infty} c_m e^{imx} e^{-inx} dx$ instead of n I am using m it is a dummy index $c_m e^{imx}$, then I have $e^{-inx} dx$. So, I am going to exchange sums and integral right. So, which it turns out is possible right.

So, because we are working with a function which satisfies Dirichlet conditions and you know the convergence theorems have been worked out we are not proving any of them right. So, this is a legitimate thing to do because of the type of functions we are working with right.

So, let us see this argument through right if you know allow for this exchange of summation and integral. So, this integral is just going to give you a 2π times δ_{mn} right, if m equal to n then you get a 2π if m is not equal to n right this integral is going to be 0 right. So, you can check this.

And, then so, what it does is basically it is going to pick out just one of these coefficients. So, in fact, this integral is going to pick out for you the one coefficient that you are interested in. So, in fact, this is a prescription for identifying any of the Fourier coefficients.

So, this is our rule. If you are given a function f of x and you want which is periodic with period 2π and you want to express this as a Fourier series involving these complex exponentials, then the coefficients are given by just this simple expression. So, the advantage with this formulation is that it is just one single expression to remember.

Can although you know you can argue for it and directly work it out whether you are doing it with the sine cosine approach or with the c_n if you have understood the logic of this. c_n is equal $\frac{1}{2\pi}$ integral minus π to plus π of $f(x) e^{-inx} dx$, right. So, this is you know nothing spectacularly new has happened here right it is just completely equivalent to the sine and cosine approach.

We could have also just started with the sine cosine series and in place of whenever you have sine you replace it with you know e^{ix} can be written as $\frac{e^{ix} - e^{-ix}}{2i}$ and $\cos x$ can be written as $\frac{e^{ix} + e^{-ix}}{2}$, right. So, if you do this in a sine cosine Fourier series you will anyway get back the same result, right.

(Refer Slide Time: 04:38)

Example

Let us expand in a Fourier series of exponentials the 2π -periodic function defined by:

$$f(x) = \begin{cases} 0, & -\pi < x < 0 \\ 1, & 0 < x < \pi \end{cases}$$

We have:

$$c_0 = \frac{1}{2\pi} \int_0^\pi e^{-i0x} dx = \frac{1}{2}$$

For $n \neq 0$,

$$c_n = \frac{1}{2\pi} \int_0^\pi e^{-inx} dx = \frac{1}{2\pi} \left[\frac{e^{-inx}}{-in} \right]_0^\pi = \frac{1 - (-1)^n}{2\pi n i}$$

Thus, we have the Fourier expansion:

$$f(x) = \frac{1}{2} - \frac{i}{\pi} \left[\frac{e^{ix} - e^{-ix}}{1} + \frac{e^{i3x} - e^{-i3x}}{3} + \frac{e^{i5x} - e^{-i5x}}{5} + \dots \right]$$

So, let us look at an example right the same example which we have already seen, but using this prescription. So, let us expand in a Fourier series of x complex exponential this 2π periodic function f of x equal to 0 in the interval $-\pi$ to 0 and 1 in the interval 0 to π .

So, we always have to be careful with this c_0 term, the coefficient corresponding to the DC part so to speak. Usually needs to be treated separately right you cannot blindly use this formula and think that you have the full answer right you always use some special caution to work out the dc coefficient. So, c_0 although the formula is the same right, but it is easy to slip in this evaluation of these coefficients, if you do not make a distinction for c_0 .

So, c_0 is 1 over 2π times just one in the interval 0 to π , right. So, the other interval does not matter $-\pi$ to 0 because you have 0 here for the function and so, you just get a half for c_0 . And, for n greater than or equal to 1 so in fact, also negative n as well, right. So, I should say $|n|$ greater than or equal to 1. So, let me just say n not equal to 0. So, for n not equal to 0 c_n is given by this expression which you can check is just 1 minus 1 to the whole power n divided by $2\pi i n$.

So, thus we have this Fourier expansion. If you collect all these terms carefully you know you can pull out a π in the denominator and there is an i in the denominator which you can shift it to the numerator and you have a minus sign you know the factor of 2 also is there and then that is also it cancels with you know one of the factors inside and then so, if you if you carefully look at all the factors involved you can write down this Fourier expansion, right.

So, you can go back to the previous discussion about you know writing this in terms of sines and cosines and convince yourself that indeed we had only sine, right. We had only sines and if you look at the way I am grouping these terms you are going to get only sines.

So, this expansion in terms of exponentials is completely equivalent to the expansion in terms of cosines and sines, but in certain contexts it is more convenient to work with you know this formulation and there are other contexts where that is more helpful, right.

(Refer Slide Time: 07:11)

$$c_0 = \frac{1}{2\pi} \int_0^{2\pi} e^{i \cdot 0 \cdot x} dx = \frac{1}{2}$$

For $n \neq 0$,

$$c_n = \frac{1}{2\pi} \int_0^{2\pi} e^{-in x} dx = \frac{1}{2\pi} \left[\frac{e^{-in x}}{-in} \right]_0^{2\pi} = \frac{1 - (-1)^n}{2\pi n i}$$

Thus, we have the Fourier expansion:

$$f(x) = \frac{1}{2} - \frac{i}{\pi} \left[\frac{(e^{ix} - e^{-ix})}{1} + \frac{(e^{i3x} - e^{-i3x})}{3} + \frac{(e^{i5x} - e^{-i5x})}{5} \dots \right].$$

The Fourier expansion in terms of complex exponentials is completely equivalent to the one with sines and cosines, but in many contexts this is more convenient.

Slide 2 of 2

So, that is all for this lecture. We will come back to exponential formulation for other kinds of problems later on, but you know this lecture is just to point out that there is an alternate completely equivalent formulation for Fourier series.

Thank you.
