The multiplicative group of a finite field

F field.
 $F^* = F - \{0\}$, a group under multiplication.
Thm: Let F be any field. Then any finite subgroup of F^* is cyclic.
~
 \mathbb{C}^* has finite subgroups:
 $H_n = \{ e^{2\pi i k/n} \mid 0 \leq k < n \}$
 \uparrow
 n th roots of unity.

Suppose F is a field. Let F^* denote the set of all non-zero elements, and so F^* is a group under multiplication. It turns out that subgroups of this group, finite subgroups of this group, are all cyclic. Theorem: Let F be a field. Then any finite subgroup of F^* is cyclic. Before we go to the proof, let me just give you some examples.

So, if you take the complex numbers, then you look at \mathbb{C}^* , then every finite subgroup of \mathbb{C}^* consists of H_n equal to $e^{2\pi i k/n}$ where $0 \leq k < n$. These are the n th roots of unity. In fact, when we prove this theorem we will see that it is a very similar situation there, that if we have a finite subgroup of F^* of order n then it consists precisely of n th roots of unity.

Proof: Suppose $H < F^*$, $|H| = n$.

Structure thm: $H \cong \mathbb{Z}/(d_1) \times \dots \times \mathbb{Z}/(d_k)$ where $d_1 \dots | d_k$
 $d_1 d_2 \dots d_k = n$.

Note: Every element $z \in H$ satisfies $z^{d_k} = 1$
So every element of H is a root of $t^{d_k} - 1$.

So we $n \leq d_k$

$\Rightarrow n = d_k, k=1,$

i.e, $H \cong \mathbb{Z}/(n)$.

So, let us proof the theorem. Suppose H is a subgroup of F^* and cardinality of H is equal to n then by the structure theorem for finite Abelian groups we have that H is isomorphic \mathbb{Z} on d_1 , cross \mathbb{Z} on d_2 cross \mathbb{Z} on d_k where d_1 divides d_2 divides d_k and the additional fact that the size of H is n it means that d_1, d_2 the product of these things is equal to n .

Now note that every element of H satisfies x to the power d_k is equal to 1 because the order of each of these cyclic groups divides d_k . And so what we have is that every element of H is a root of the polynomial t to the power d_k minus 1. But this polynomial can have at most d_k many roots because it is of degree d_k . And so we have that n is less than or equal to d_k .

So, this is only possible if n is equal to d_k and in fact, k is equal to 1. I would just say n is equal to d_1 . So, i.e H is isomorphic to $\mathbb{Z} \text{ mod } n$. So, that concludes the proof of the theorem every finite subgroup of the multiplicative group of 80 feet is cyclic, in fact, which is of order n it is isomorphic $\mathbb{Z} \text{ mod } n$.

Thm: If E is a field of order p^n , then $E^* \cong \mathbb{Z}/(p^n-1)$.

Pf: E^* is a finite subgroup of E^* .

Upshot: $E^* = \{1, \alpha, \alpha^2, \dots, \alpha^{p^n-1}\}$
for some $\alpha \in E^*$.

So, now let us look at finite fields, so the multiplicative group of finite field. So, theorem and this actually is an obvious corollary of this previous result if. So, if E is a finite field. If E is a field of order p to the n , then the multiplicative group of E is isomorphic to the cyclic group \mathbb{Z} mod p to the n minus 1. Proof when E^* is a finite subgroup of E^* . It is yeah it is the full group and it is finite because E is finite, so E^* is finite. And so the previous theorem applies, right.

So, E^* has to be cyclic and its order is p to the n minus 1. So, it is a cyclic group of order n minus 1. The upshot of this is that E^* can be written as $1, \alpha, \alpha^2, \dots, \alpha^{p^n-1}$ you can pick an element α a non-zero element of the field such that every element of the field can be written as a power of that original element, okay. So, that is a very powerful property and we will see some applications of that in the next lecture.
