Week 3: Problem Session

1. Suppose $z \in \mathbb{C}$. Show $z \in \overline{\mathbb{Q}} \Leftrightarrow \bar{z} \in \overline{\mathbb{Q}}$.

Soln: If $z \in \overline{\mathbb{Q}}$, $\exists p(t) \in \mathbb{Q}[t]$ such that $p(z) = 0$.

$$p(t) = a_0 + a_1 t + \dots + a_n t^n.$$

$$0 = \overline{p(z)} = \overline{a_0 + a_1 z + \dots + a_n z^n} = a_0 + a_1 \bar{z} + \dots + a_n \bar{z}^n$$

$$= p(\bar{z}).$$

$\therefore \bar{z} \in \overline{\mathbb{Q}}$.

Let us solve some problems. For the first problem, recall that $\overline{\mathbb{Q}}$ denotes a set of complex numbers that are algebraic over \mathbb{Q} . And the problem states that suppose Z is a complex number, then Z belongs to $\overline{\mathbb{Q}}$, if and only if \bar{Z} belongs to $\overline{\mathbb{Q}}$. Now, you can pause the video and try to solve it yourself. And if you cannot do it, then go ahead and watch me solve it. What does it mean for Z to be in $\overline{\mathbb{Q}}$.

So, if Z is in $\overline{\mathbb{Q}}$, then there exist a polynomial $p(t)$ in $\mathbb{Q}[t]$ such that $p(z)$ is equal to 0. Now, let us look at this polynomial say $p(t)$ is equal to a_0 plus $a_1 t$ plus $a_n t$ to the power n . Now I claim that p of \bar{z} is also 0. This is because well, 0 is p of z taking complex conjugates, we get that p of \bar{z} the whole thing bar is 0. But this is a_0 plus $a_1 \bar{z}$ plus $a_n \bar{z}$ to the n . And then we take bar of this whole, not \bar{z} sub n , \bar{z} to the power n , we take bar of this whole thing.

With these coefficients a_0 a_1 up to a_n are rational and therefore, they are in fact real numbers. So, I can write this as a_0 plus $a_1 \bar{z}$ plus $a_n \bar{z}$ to the n bar. But this is nothing but p of \bar{z} bar. So, if z satisfies a polynomial $p(t)$, then \bar{z} also satisfies the same polynomial $p(t)$, if that polynomial has coefficients, which are real numbers. Since rational numbers are real numbers, \bar{z} again satisfies this polynomial $p(t)$.

And that shows that if z is in \bar{Q} , the other way is by symmetry, because \overline{z} is equal to z . So, if \overline{z} is in \bar{Q} , then z , which is $\overline{\overline{z}}$, is also in \bar{Q} . So, you do not really need to do that separately.

(Refer Slide Time: 02:58)

2. Let $\bar{Q}_R = \{x \in \mathbb{R} \mid x \text{ is algebraic over } \mathbb{Q}\} = \bar{Q} \cap \mathbb{R}$.

Show that $\bar{Q} = \{a+ib \mid a, b \in \bar{Q}_R\}$.

Soln: If $a, b \in \bar{Q}_R$.

Then $a+ib \in \mathbb{Q}(a, b, i)$.

Since a, b, i are algebraic, $[\mathbb{Q}(a, b, i) : \mathbb{Q}] < \infty$.

$\therefore a+ib$ lies in a finite extn. of \mathbb{Q} , hence is alg. over \mathbb{Q} .

so $a+ib \in \bar{Q}$.

$\mathbb{Q}(a, b, i)$
 $|\cdot| < \infty$
 $\mathbb{Q}(a, b)$
 $|\cdot| < \infty$
 $\mathbb{Q}(a)$
 $|\cdot| < \infty$
 \mathbb{Q}

Now let us move on to problem two. So, for this problem, let us define a subfield of \mathbb{C} . Let, I will call it \bar{Q}_R . It is the set of complex numbers z , well, no, I would say the set of real numbers α such that α is algebraic over \mathbb{Q} . So, this is nothing but $\bar{Q} \cap \mathbb{R}$. And the problem is show that \bar{Q} is equal to $a+ib$, where a and b belong to \bar{Q}_R .

Now you can pause the video and try to solve this yourself. If you cannot, then I will solve it for you. So firstly, what we will show is that if a and b are in \bar{Q}_R , then $a+ib$ is in \bar{Q} . And conversely, if $a+ib$ is in \bar{Q} , then a and b are in \bar{Q}_R . So, let us start with the assumption that a and b are in \bar{Q}_R and we want to show that $a+ib$ is in \bar{Q} .

So, then $a+ib$ belongs to the field generated by \mathbb{Q} , a , b and i . But a , b and i are all algebraic. So, this is a finite extension of \mathbb{Q} . So, $a+ib$ is algebraic, because they are in \bar{Q} , i is algebraic because $i^2 = -1$. If you are not sure why this is true, I would suggest you work it out. You can show it by looking at a tower of fields $\mathbb{Q} \subset \mathbb{Q}(a, b, i) \subset \mathbb{Q}(a, b) \subset \mathbb{Q}(a) \subset \mathbb{Q}$ and showing that each of these extensions is finite.

Basically, you can bound the extension of $\mathbb{Q}(a, b, i)$ over \mathbb{Q} by the degree of $\mathbb{Q}(i)$ over \mathbb{Q} . We have seen these kinds of arguments before in the lecture. So, this extension being generated by algebraic elements is algebraic. And therefore, $a + ib$, since it lies in an algebraic in a finite extension, hence is algebraic over \mathbb{Q} . So, $a + ib$ belongs to $\overline{\mathbb{Q}}$. The other way is a little more involved.

(Refer Slide Time: 06:32)

If $a+ib \in \overline{\mathbb{Q}}$, $a, b \in \mathbb{R}$.

Since $a+ib \in \overline{\mathbb{Q}}$ and $a-ib \in \overline{\mathbb{Q}}$, $[\mathbb{Q}(a+ib, a-ib) : \mathbb{Q}] < \infty$.

$$a = \frac{a+ib + a-ib}{2} \quad b = \frac{a+ib - (a-ib)}{2i}$$

So $a, b \in \mathbb{Q}(a+ib, a-ib)$

$\Rightarrow a, b \in \overline{\mathbb{Q}} \Rightarrow a, b \in \overline{\mathbb{Q}} \cap \mathbb{R} = \overline{\mathbb{Q}} \cap \mathbb{R}$.

Now, if $a + ib$ belongs to $\overline{\mathbb{Q}}$, we want to show that a and b are real numbers. We want to show that a and b lie in $\overline{\mathbb{Q}} \cap \mathbb{R}$. Now $a + ib$ belongs to $\overline{\mathbb{Q}}$. No, let us not do it like that. So first we will use the, we will use problem one. Problem one says that if $a + ib$ belongs to $\overline{\mathbb{Q}}$, then $a - ib$ also belongs to $\overline{\mathbb{Q}}$.

So, what we have is since $a + ib$ and $a - ib$ belong to $\overline{\mathbb{Q}}$, we have $\mathbb{Q}(a + ib, a - ib)$ is a finite extension of \mathbb{Q} and so because again, by the same argument, it is generated by two algebraic elements. But a can be written as $\frac{a + ib + a - ib}{2}$ and b can be written as $\frac{a + ib - (a - ib)}{2i}$.

So, a and b lie in this field $\mathbb{Q}(a + ib, a - ib)$, which is extension of finite degree. Therefore, a and b belong to $\overline{\mathbb{Q}}$, which implies that a and b belong to $\overline{\mathbb{Q}} \cap \mathbb{R}$, which is $\overline{\mathbb{Q}} \cap \mathbb{R}$, just by definition of $\overline{\mathbb{Q}} \cap \mathbb{R}$, we assume that a and b are real numbers. So here is the thing that if $a + ib$ is algebraic, then its real part a and its imaginary part b are algebraic real numbers.

3. Let $\overline{\mathbb{F}_p}$ denote the algebraic closure of \mathbb{F}_p (p prime). 

For any $n \geq 1$, $\overline{\mathbb{F}_p}$ has a unique subfield of order p^n .

Soln: $E_n = \{z \in \overline{\mathbb{F}_p} \mid z^{p^n} - z = 0\}$.

$D(z^{p^n} - z) = -1$, so by the derivative criterion for repeated roots, $z^{p^n} - z$ has p^n distinct roots in $\overline{\mathbb{F}_p}$.

So $|E_n| = p^n$.

Also E_n is a field.

Let us move on to problem three, which concerns the algebraic closure of a field of positive characteristic. So, let $\overline{\mathbb{F}_p}$. So, your \mathbb{F}_p denotes the field with p elements, where p is a prime number. Then for any integer n , any positive integer n , maybe I should say n greater than 1. No, I can take n equals 1. So, for any integer positive integer n , $\overline{\mathbb{F}_p}$ has a unique sub field of order p^n .

This is quite similar to the analysis we did when we looked at, we looked at the classification of finite fields and when one finite field contains the other, so you can try solving it yourself. And if not, can watch me solve it. So here is the solution. So, just define E_n to be the set of all elements x in $\overline{\mathbb{F}_p}$, such that $x^{p^n} - x = 0$.

Then note that if we take this polynomial $x^{p^n} - x$, D of this polynomial is equal to minus 1 because p^n is 0 in a field of characteristic p . So, by the derivative criterion for repeated roots, $x^{p^n} - x$ has p^n distinct roots and all of them lie in $\overline{\mathbb{F}_p}$ because $\overline{\mathbb{F}_p}$ is the algebraic closure of \mathbb{F}_p .

So, it has p^n distinct roots in $\overline{\mathbb{F}_p}$. And so, cardinality of E_n is p^n . Also, E_n is a field. I will not work out the detailed solution of this, we have already seen it when we were classifying finite fields. So, you just have to show that if x and y are roots of this polynomial, then $x + y$ and xy are also roots of this polynomial.

And the interesting case is for $x + y$ where you use the binomial theorem, but when you use the binomial theorem with the power of p , then all but two terms will become 0, because

those all the binomial coefficients except for the first and the last one will be divisible by p . So, using that you can show that E_n is a field. So, what we see, we see here is that $\overline{F_p}$ has a field of order p^n . So E_n is a field, sub field of $\overline{F_p}$ of order p^n .

(Refer Slide Time: 12:45)

Suppose $F_n \subset \overline{F_p}$ is a subfield of order p^n .
 Then (F_n^*, \cdot) is a group of order $p^n - 1$.
 $\therefore \forall z \in F_n^*, z^{p^n - 1} = 1 \Rightarrow z^{p^n} - z = 0 \Rightarrow z \in E_n$
 Hence $F_n \subset E_n$, since $|F_n| = |E_n| = p^n$, $F_n = E_n$.

Now, we want to show that this is the only subfield of order p^n . So now suppose F_n , well, maybe this notation is a bit ambiguous. So, but okay, I am not using bold letters. So F_n subset of $\overline{F_p}$ is a subfield of order p^n . Then you can look at the nonzero elements of F_n . And you can look at them under multiplication is group of order $p^n - 1$, we just removed 0.

So, therefore, for every x in F_n^* , $x^{p^n - 1} = 1$, which implies that $x^{p^n} - x = 0$, which is just saying that x belongs to the field E_n , that we had considered earlier. And hence, F_n is contained in E_n , of course, 0 is in E_n too and every nonzero element of F_n is in E_n . But since F_n and E_n have the same order. We have $F_n = E_n$, So E_n which consists of solutions of the equation $x^{p^n} - x = 0$ is the only subfield of $\overline{F_p}$ of order p^n .
