Uniqueness of Splitting Fields

(Refer Slide Time: 00:16)

Let us talk about the Uniqueness of Splitting Fields. So, here is a formal statement proposition, let F be a field and f denote a polynomial. If K and K' are two splitting fields, are both splitting fields, are splitting fields of f , then they are isomorphic. In fact, more precisely there exists an isomorphism of fields, isomorphism of fields call it ϕ from K to K' such that when you restrict that to F , it just gives you the identity map.

So, let us prove this. So, recall, it is good to draw the picture always. So, we have the following picture, the base field is F and I have two extensions K and K' and they are both splitting fields of the same polynomial. And what we are claiming is that there exists a map, an isomorphism between these two fields, such that when you restrict that isomorphism to F , it just gives you the identity map.

So, that is what we need to show, and you may recall that, a similar thing has already been proved for the algebraic closure. So, let us just use the previous result that something analogous to this holds for algebraic closures. So, let me start by bringing the algebraic closures into the picture. So, let L and L' be algebraic closures of K and K' .

(Refer Slide Time: 02:57)

Uniqueness of splitting fields

Prop: Let F be a field and $f \in F[x]$. If K and K' are splitting fields of f , then \exists an isomorphism of fields $\phi: K \rightarrow K'$ such that $\phi|_F = \text{id}_F$.

Proof:

alg	{	alg	{	L		L'
				K		K'
				F		F

Let L and L' be algebraic closures of K and K' .
 L and L' are algebraic closures of F .

So, which means that my picture in some sense is the following that narration to this tower of extensions I sort of put one more on top which is L and L dash. So, the additional property here is that L and L dash are algebraically closed. Now, observe that L and L dash are also algebraic closures of F . Why is that?

Because we call what is an algebraic closure, it is an algebraic extension of the base field which is also algebraically closed. So, now, in this case you know K or F is splitting field in particular it is algebraic, in fact, we have shown it is finite. So, this is an algebraic extension. I chose L to be an algebraic closure of K , which means L over K is an algebraic extension.

And we call the tower property of algebraic extensions, if we have, a sequence of algebraic extensions like this then the field on top is algebraic over the field on the bottom. So, this implies L is algebraic over F , an algebraic extension and of course, L is algebraically closed. So, that implies that L is an algebraic closure of the field F itself. So, this tells us that L and L dash are algebraic closures of the same field F .

(Refer Slide Time: 04:23)

By the uniqueness of algebraic closures, \exists an isomorphism

$$\varphi: L \rightarrow L' \text{ st } \varphi|_F = \text{id}_F.$$

Claim: $\varphi(K) = K' \parallel$

Proof: Let $\alpha_1, \dots, \alpha_n \in K$ be the roots
 $\alpha'_1, \dots, \alpha'_n \in K'$
of F over K and K' .

$$K = F(\alpha_1, \dots, \alpha_n) \quad \varphi(\alpha_i) = ?$$

And now, we use the uniqueness property by the uniqueness of algebraic closures, what we know is that there exists an isomorphism and isomorphism of fields φ from L to L' , such that φ when restricted to the base field F is just the identity map on F . So, going back to the picture that we drew already, so this is really our field F , this is the tower here. And now we just go back and put the same thing here.

So, what we now know is the following that there is a now, there is now a map. Let us call it φ , such that when you restrict it to F , it gives you the identity. But of course, we wanted to prove the very same fact about K and K' . And to do that, we simply claim that if you restrict φ to K , well, the image of φ of K is exactly the field K' .

So, if you prove this, then you are done, because then all you have to do is to restrict the map φ to K , and that restriction will give you a map onto K' . So, it will become a one to one map, it will become the isomorphism that we want. So, let us prove this fact. So, the first statement, well, we need to use something about K and K' . Recall that they are the splitting fields of the polynomial F .

So, we know that F splits over K as well as over K' . So, let us call the zeroes of F something. So, let $\alpha_1, \dots, \alpha_n$ belong to K and $\alpha'_1, \alpha'_2, \dots, \alpha'_n$ be elements of K' , be the zeroes of F , be the roots of F , be the roots of the polynomial F in or over K and K' . These are the roots over K and K' .

Now, we also know because they are the splitting fields that K is generated by F and the roots, K similarly is generated by F and the roots. But let us ask. So, K , let us start with K , K we know is generated with, the subfield of K generated by F and the roots of the polynomial F are exactly, is exactly, is just the field K itself. Now, let us ask what can we say about the action of ϕ on the α_i 's? The α_i 's are generators. And to determine the image of ϕ here, it is sort of enough to work out the image of the generators.

(Refer Slide Time: 07:44)

$$f(x) = a_0 + a_1x + \dots + a_nx^n \quad a_i \in F$$

$$f(\alpha_i) = a_0 + a_1\alpha_i + \dots + a_n\alpha_i^n = 0$$

Apply ϕ to both sides

$$\phi(a_0) + \phi(a_1)\phi(\alpha_i) + \dots + \phi(a_n)\phi(\alpha_i)^n = 0$$

$$a_0 + a_1\phi(\alpha_i) + \dots + a_n\phi(\alpha_i)^n = 0$$

$$\Rightarrow f(\phi(\alpha_i)) = 0$$

$\underbrace{\phi(\alpha_i)}_{\in L'}$

So, observe that what is α_i the root of the polynomial F . So, if f of x is a polynomial a_0 plus a_1x plus bla bla bla, an x power n a_n is our all coefficients from F , then what we know is that if you plug in any of the α_i 's, so if you plug in α_i for x , then that gives me 0. So, in other words, f of x at an α_i power n is 0. Now, we apply ϕ to both sides of this equation.

So, we will take this equation and apply ϕ to both sides. So, ϕ it will just change this to an equation in L' rather than L . Now, what do you get? Well, the left-hand side becomes ϕ of a_0 plus ϕ of a_1 ϕ of α_i what I write that using the homomorphism property, like this, ϕ of a_n ϕ of α_i the whole to the n is equal to ϕ of 0, which is 0 itself. I have used all the homomorphism properties of ϕ .

And now recall that ϕ was identity on F . So, ϕ of a_0 is just a_0 itself, plus this coefficient ϕ a_1 does not change. It is a_1 again ϕ α_i , and so on. So, this is just going to be an ϕ α_i to the n 0. And well, what does that mean?

It just says that the element $\phi(\alpha_i)$ is again a root of the polynomial F , except of course, α_i is in L , you know, it is on the other side. It is an element of L rather than an element of K . But all we are saying is that if you apply you take a root of F in L , and you apply ϕ to it, what you get is a root of F in L .

(Refer Slide Time: 09:55)

But we know that the roots of f in L are $\alpha_1, \dots, \alpha_n$

L
 \downarrow
 K
 \downarrow
 F

$\Rightarrow \phi(\alpha_i) = \alpha_j$ for some $1 \leq j \leq n$

$\phi(F(\alpha_1, \dots, \alpha_n)) \subseteq F(\alpha_1, \dots, \alpha_n)$

$\phi(K) \subseteq K$

Now repeat argument with roles of K, K' interchanged
 & ϕ replaced by ϕ^{-1} .

Now, but we sort of know what the roots of F in L are, but we know that roots of F over the field L are exactly the α_i s. Why is that? Well, you may say that well, those are actually the roots of the field F in K rather than in L . K is a smaller field L is larger, but if you know the roots in a smaller field, so, if here are all the roots F splits completely over K .

So, all n roots have been obtained, and they are elements of K , then when you view the same polynomial as a polynomial over a larger field, the roots continue to be the same. So, you cannot get any any additional roots when you go to a larger extension field because all n roots have already been realised inside K .

So, I am just repeating sort of things which you have seen before. But what this implies is the following, this means that when I apply ϕ on α_i that is supposed to be one of the roots of F in L and therefore, it must be one of the α_j s, for some j between 1 and n . And this is true for each i . So, for each i , so, this is for you fix an i from 1 to n , and you apply ϕ on the root α_i , it must be one of the α_j s.

So, what this means is that if you think about the image of ϕ , which is what we are trying to compute, if you apply ϕ to K elements of K are just elements of the extension field $F \alpha_1, \alpha_2, \dots, \alpha_n$. Then this is just going to be well, it is going to be a subset if you wish of, so, when you apply ϕ to this, this is going to be a subset of F adjoined. So, what are the possible images of $\alpha_1, \alpha_2, \dots, \alpha_n$ under ϕ , they are just some of the α_j primes.

So, whatever it is you are going to get an answer which lies inside the subfield of L generated by F and $\alpha_1, \alpha_2, \dots, \alpha_n$. So, this is exactly the statement that $\phi(K)$ is a subset of K , because the right-hand side is exactly K . But now, we just sort of repeat the argument with K and K' sort of interchanged, repeat the argument with K and K' interchanged. And ϕ , replaced by the inverse isomorphism.

(Refer Slide Time: 13:22)

$$\phi(K') \subseteq K \Rightarrow K' \subseteq \phi(K) \subseteq K'$$

observe: ϕ maps the multiset $\{\alpha_i\}^n$ of roots of f in K to $\{\alpha'_i\}^n$ the multiset of roots of f in K' .

So, you just switch the order of everything, just think of K to K' maps, from K' to K or maps, from L to L and so, and just repeat the same arguments, then what you conclude is that ϕ^{-1} acting on K' is a subset of K . Now, what does this mean? Of course, this says that I can apply ϕ to both sides of this equation it says K' is a subset of $\phi(K)$.

Now, we have already shown the first part of the argument said that $\phi(K)$ was a subset of K' and that is exactly what we wanted to prove. So, now we are done. So, what we are managed to show is by passing to the algebraic closure and constructing an isomorphism at

the level of algebraic closures, that map restricts to an isomorphism between the two splitting fields. So, this proves the uniqueness of the the splitting fields.

And the little fact that came up in the proof is of course, useful observe that what we also showed is that this map between the splitting fields has the following property that ϕ maps the multiset of roots of F to, so, this is the multiset of roots in over K it maps those to the multiset of roots. So, this is the multiset of roots of F in K , this is mapped to α_i dash. Which is what? It is just the the multi set of roots of F in K dash.

So, it maps roots, the set of roots or the multi set of roots to the multi set of roots. So that is something that is useful to keep in mind.
