Isomorphic Extensions

Extensions K and L are said to be isomorphic

$\begin{array}{c} K \\ | \\ F \end{array}$ and $\begin{array}{c} L \\ | \\ F \end{array}$

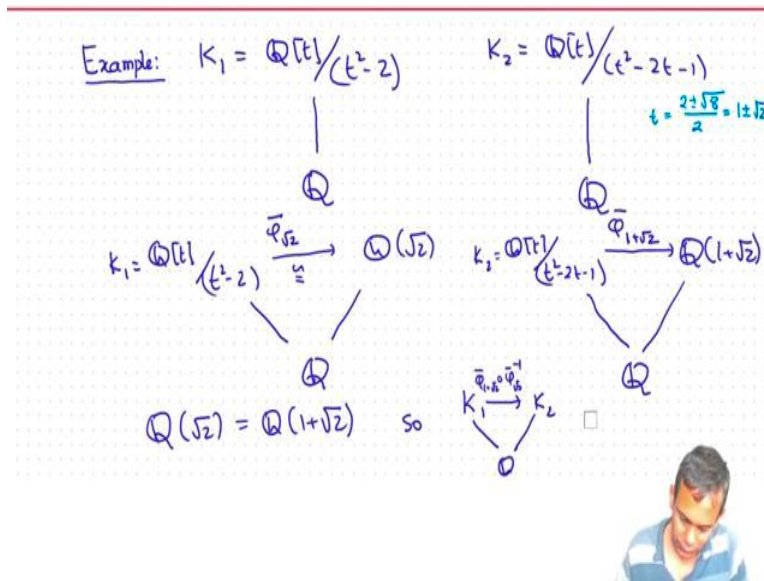

if there exists an isomorphism $\varphi: K \rightarrow L$ such that

$\varphi|_F = \text{id}_F$.

Extensions, say K over F and L over F are said to be isomorphic, if there exists an isomorphism $\varphi: K \rightarrow L$. But there is an additional condition that φ restricted to F is equal to the identity function from F to F . So, for all practical purposes two field extensions are thought of as the same if you can find an isomorphism of the larger fields, which keeps the elements of the smaller field fixed. So, which maps each element of the smaller field into the corresponding element of the smaller field in the other extension. Let us look at an example.

(Refer Slide Time: 01:32)

Look, let us look at K_1 equals $\mathbb{Q}[t] \text{ mod } (t^2 - 2)$. This, we are familiar with $t^2 - 2$ is an irreducible polynomial. And so, this ideal $(t^2 - 2)$ is a maximal ideal in $\mathbb{Q}[t]$. And so, $\mathbb{Q}[t] \text{ mod } (t^2 - 2)$ is a field and it contains \mathbb{Q} . And let us construct another one, K_2 . And let us say this is $\mathbb{Q}[t] \text{ mod } (t^2 - 2t - 1)$. So, this again is an extension over \mathbb{Q} . And let us see if we can figure out whether these two extensions are isomorphic or not. Now, on the face of it, they both have degree 2, so they could be isomorphic.

Now, we already have some understanding of this first field extension, we know that, if you take $\mathbb{Q}[t] \text{ mod } (t^2 - 2)$, this is isomorphic to $\mathbb{Q}(\sqrt{2})$ over \mathbb{Q} , why? Well, you just take the map $\bar{\varphi}_{\sqrt{2}}$. We saw that this gives rise to an isomorphism. And the way we define it, the elements of \mathbb{Q} go to elements of \mathbb{Q} because they just correspond to constant polynomials on this side. So, this is an isomorphism. So, this is K_1 . And what about K_2 , so let us just see what the roots of this polynomial $t^2 - 2t - 1$ are.

Well, if you just think about it, the roots are $t = 2 \pm \sqrt{4 + 4} = 2 \pm 2$, which is $1 \pm \sqrt{2}$. So, in a similar manner, we can think of this K_2 as $\mathbb{Q}[t] \text{ mod } (t^2 - 2t - 1)$ with using the map $\bar{\varphi}_{1+\sqrt{2}}$, say $1 + \sqrt{2}$. This goes to $\mathbb{Q}(1 + \sqrt{2})$. And this is an isomorphism over \mathbb{Q} . But of course, $\mathbb{Q}(\sqrt{2})$ is the same as $\mathbb{Q}(1 + \sqrt{2})$. Why is that?

Well, if you have a field that contains $\sqrt{2}$, and it contains \mathbb{Q} , then it must contain $1 + \sqrt{2}$. Conversely, if you have a field that contains $1 + \sqrt{2}$ and contains \mathbb{Q} , then it must

contain root 2. So, these are actually the same, every field that contains \mathbb{Q} and root 2 is also a field that contains \mathbb{Q} and $1 + \sqrt{2}$ and vice versa. And so, we have that K_1 and K_2 are isomorphic over \mathbb{Q} . We have this isomorphism, which we can call, let us say $\bar{\phi}$ $1 + \sqrt{2}$ $\bar{\phi}^{-1}$ is an isomorphism from K_1 to K_2 , and these are isomorphic over \mathbb{Q} .

(Refer Slide Time: 05:16)

Now, suppose we have 2 field extensions, let us say, K over F . And we have an element α here, and another field extension L over F an element β over here. So, then we can talk about the field $F(\alpha)$, we can talk about the field $F(\beta)$, which lies over there. So then, in general, is not very easy to figure out whether or not $F(\alpha)$ and $F(\beta)$ are isomorphic over here. But if you look at a slightly more restricted notion of isomorphism, then there is a very beautiful and simple answer.

(Refer Slide Time: 05:54)

Thm: $\alpha \in K$, $\beta \in L$, α & β are algebraic.

Then there exists an isomorphism $K \xrightarrow{\varphi} L$ such that $\varphi(\alpha) = \beta$

if and only if the irreducible poly of α over F equals the irreducible polynomial of β over F .

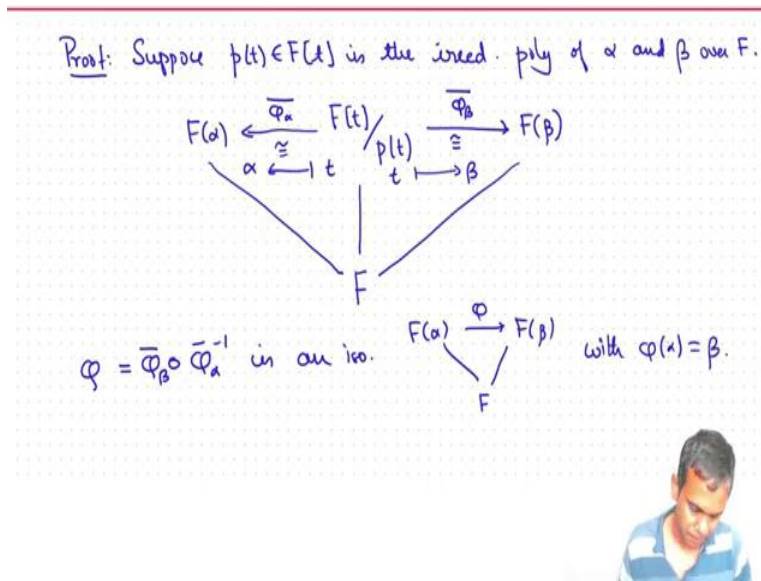

So that is the next theorem. So, now, suppose we have this situation, where we have an α in a field extension over F , β in a field extension L over F , and α and β are algebraic. See $F[\alpha]$ and $F[\beta]$ are both transcendental then, of course, $F[\alpha]$ is isomorphic to the field of rational functions over F , $F[\beta]$ is also isomorphic to that same field and so $F[\alpha]$ is isomorphic to $F[\beta]$. And if α is algebraic but β is transcendental then $F[\alpha]$ is a finite-dimensional vector space over F , whereas $F[\beta]$, when β is transcendental is going to be infinite dimension.

So, we know that $F[\alpha]$ cannot be isomorphic to $F[\beta]$. So the only interesting case for the isomorphism question is when α and β are algebraic. So, case of the statement is that then there exists an isomorphism φ from K to L . So, I am going to draw it like this. So, this means that φ is an isomorphism from K to L , but when restricted to F φ is the identity, so it is an isomorphism of extensions, not just a ring isomorphism. But we are going to add an additional condition such that $\varphi(\alpha) = \beta$.

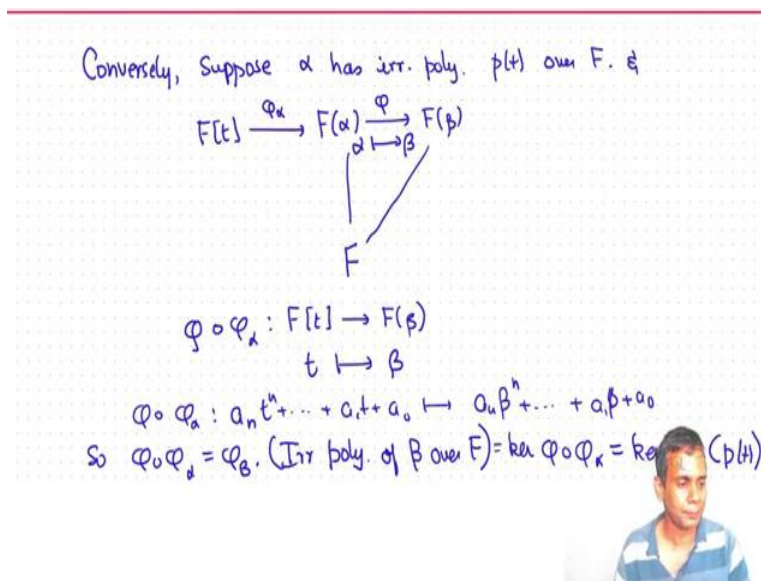

Now, once you add this condition, this decision problem becomes much easier, then, if and only if the irreducible polynomial of α over F equals the irreducible polynomial of β over F . So, when you put this additional condition that φ must map α to β , then this problem becomes much simpler. And see the reason why this particular problem is more interesting, is very interesting when we study Galva theory.

(Refer Slide Time: 08:47)

So, here is the proof. So, to start with, let us assume that alpha and beta have the same irreducible polynomial over F. So, suppose $p(t)$ belongs to $F[t]$ is the irreducible polynomial of alpha as well as beta over F. So, then, we have $F[t] \text{ mod } p(t)$, on the one hand, this $\bar{\varphi}_\alpha$ gives an isomorphism to $F(\alpha)$ $\bar{\varphi}_\beta$ gives an isomorphism to $F(\beta)$. And these are all isomorphisms over F. And under this isomorphism, t goes to alpha under this isomorphism t goes to beta. And so now if you take $\bar{\varphi}_\beta \circ \bar{\varphi}_\alpha^{-1}$ then this is an isomorphism from $F(\alpha)$ to $F(\beta)$ over F with $\varphi(\alpha) = \beta$, where alpha goes to t , t goes to beta equal to beta that proves one way.

(Refer Slide Time: 08:47)

And for the converse suppose that α has irreducible polynomial $p(t)$ over F . And suppose that, we have an isomorphism from $F[\alpha]$ to $F[\beta]$, is an isomorphism, which takes α to β . Now, we have from $F[t]$, we have the map ϕ_α , the substitution map to $F[\alpha]$. And if you consider the map $\phi_\beta \circ \phi_\alpha$, this is a homomorphism from $F[t]$ to $F[\beta]$. And this takes t to β . Since it is a ring homomorphism, it also takes $a_n t^{n+1} + \dots + a_0$ to $a_n \beta^{n+1} + \dots + a_0$.

So, this gives rise to map from $F[t]$ to $F[\beta]$, but you recognize this as the map where you are substituting for each polynomial the variable t to be β . So, what we have is that $\phi_\beta \circ \phi_\alpha$ is just ϕ_β . So, the irreducible polynomial of β over F is the kernel of $\phi_\beta \circ \phi_\alpha$, but that is the kernel of ϕ_α because ϕ_β is an isomorphism. But this is the generator of the kernel of the ideal generated by the irreducible $(p(t))$ (13:20) β over F is this but this is the ideal generated by $p(t)$ and so, $p(t)$ must be the irreducible polynomial of β over F .

(Refer Slide Time: 13:34)

Theorem: Let $\varphi: K \rightarrow K'$ is an isomorphism of field extns.

$\begin{array}{c} K \rightarrow K' \\ \swarrow \searrow \\ F \end{array}$

Suppose $\alpha \in K$, $f \in F[t]$, are such that $f(\alpha) = 0$.

Then $f(\varphi(\alpha)) = 0$. $f(t) = a_n t^n + \dots + a_1 t + a_0$

Proof: $f(\varphi(\alpha)) = a_n \varphi(\alpha)^n + \dots + a_1 \varphi(\alpha) + a_0$

$$= \varphi(a_n) \varphi(\alpha)^n + \dots + \varphi(a_1) \varphi(\alpha) + \varphi(a_0)$$

$$= \varphi(a_n \alpha^n + \dots + a_1 \alpha + a_0)$$

$$= \varphi(f(\alpha)) = \varphi(0) = 0$$

An important property of isomorphisms of extensions is that if you take an element in one extension with a certain irreducible polynomial and you map it under an isomorphism to another field extension, then its image will have the same irreducible polynomial in the second extension. Let me state this precisely suppose, ϕ from K to K' prime over F is an isomorphism of field extensions. And suppose α belongs to K is an element such that $f(t)$ is a polynomial in $F[t]$ are such that $f(\alpha) = 0$ then $f(\phi(\alpha))$ is also going to be 0. This is rather straightforward. So, let us just look at $f(\phi(\alpha))$.

So, let us say that f of t is the polynomial $a_n t^n + \dots + a_1 t + a_0$, then f of $\phi(\alpha)$ is $a_n \phi(\alpha)^n + \dots + a_1 \phi(\alpha) + a_0$. Now, a_n, \dots, a_1, a_0 , these are all elements of F . So, $\phi(a_i) = a_i$. So, I can write this as $\phi(a_n \phi(\alpha)^n + \dots + \phi(a_1 \phi(\alpha) + \phi(a_0))$. Now we are applying ϕ to all the terms here and they are just sums and products. So, because ϕ is a ring homomorphism, this is the same as $\phi(a_n \alpha^n + \dots + a_1 \alpha + a_0)$, which is just $\phi(f(\alpha))$, which is $f(\alpha)$, which is 0. That is the proof.

(Refer Slide Time: 16:07)

Example: $p(t) = x^3 - 2 \in \mathbb{Q}[t]$ is irreducible
 Let $\alpha = \sqrt[3]{2}$
 $\zeta = e^{2\pi i / 3}$
 The roots of $p(t)$ in \mathbb{C} are $\alpha, \alpha\zeta, \text{ and } \alpha\zeta^2$.
 $\mathbb{Q}(\alpha) \cong \mathbb{Q}(\alpha\zeta) \cong \mathbb{Q}(\alpha\zeta^2)$
 $\mathbb{Q}(\alpha) \subset \mathbb{R}$
 $\mathbb{Q}(\alpha\zeta) \not\subset \mathbb{R}, \mathbb{Q}(\alpha\zeta^2) \not\subset \mathbb{R}$

Now let us look at an example. So, consider the polynomial $p(t) = x^3 - 2$. So, this is an irreducible polynomial in $\mathbb{Q}[t]$. This polynomial has no rational roots, what are the roots of this polynomial? So, let us say $\alpha = \sqrt[3]{2}$. And let us say $\zeta = e^{2\pi i / 3}$. So, this is a cube root of 1 in the complex numbers, $\zeta^3 = 1$. Then the roots of $p(t)$ are in the complex numbers, $\alpha, \alpha\zeta$ and $\alpha\zeta^2$. So, we have 3 fields, we have $\mathbb{Q}(\alpha), \mathbb{Q}(\alpha\zeta)$ and $\mathbb{Q}(\alpha\zeta^2)$.

And each of these elements $\alpha, \alpha\zeta$, and $\alpha\zeta^2$, they all have the same irreducible polynomial over \mathbb{Q} , namely, the polynomial $x^3 - 2$. $x^3 - 2$ is the irreducible polynomial of all these 3 elements over \mathbb{Q} . And therefore, these are all isomorphic over \mathbb{Q} . These 3 extensions are isomorphic over \mathbb{Q} . But notice that $\mathbb{Q}(\alpha)$ is a subfield of the real numbers, whereas $\mathbb{Q}(\alpha\zeta)$ is not a subfield of the real numbers and $\mathbb{Q}(\alpha\zeta^2)$ also is not a subfield of the real numbers.

And so, this means that if you want to think about these field extensions properly, it is important to sort of free them from the context of the real numbers and think of them as sort of abstract objects. And this is where the notion of isomorphism of extensions comes into being. So, an abstract property of a field extension something that is invariant under field isomorphism being a subfield of the real numbers is not such a property.
