Free abelian groups and quotient groups

(Refer Slide Time: 00:15)

\mathbb{Z} -Free modules :

Let S be a set. A free abelian group (or \mathbb{Z} -module) on S is a pair (F, γ) where F is a \mathbb{Z} -module and $\gamma: S \rightarrow F$ (map of sets) such that the following universal property holds: Given any pair (N, f) with N a \mathbb{Z} -module and $f: S \rightarrow N$ a set map, \exists a unique map $\tilde{f}: F \rightarrow N$ st \tilde{f} is \mathbb{Z} -linear and $\tilde{f} \circ \gamma = f$.

$$\begin{array}{ccc} S & \xrightarrow{f} & N \\ \gamma \downarrow & \nearrow \tilde{f} & \\ F & & \end{array}$$

So, we have seen that the tensor product is a certain kind of a universal object but we still have not constructed the tensor product explicitly yet. So let us do that now, but before we do that let us look at two other examples of universal objects which will be required as intermediaries in the construction of the tensor products.

So, let me give you two more examples which you have seen in some form before. So, the first one is free modules or free modules of the integer free \mathbb{Z} -modules or Free Abelian Groups. So what is the free abelian group on a set. So given a set, so let me define it like this a free abelian group or \mathbb{Z} -module on S is again a pair F comma γ where F is a \mathbb{Z} -module and γ is a map from S to F just a map of sets, just a function.

With the additional property such that the following universal property holds and what is the property? Given any pair like this, given any pair N comma f with N , \mathbb{Z} -module and f a set map and as before we will draw the same sort of diagram that we drew for the tensor product definition itself, so S to F I have γ . Now I am going to take an arbitrary pair S to N , there is

an f then given any such pair what the universal property asserts is that there is a map f tilde from F to N which is a homomorphism of abelian groups.

So, given any such pair like this there exists a unique homomorphism. There is a unique map f tilde from F to N such that two properties, f tilde is a homomorphism of groups. In other words it is a \mathbb{Z} -linear map and property two, the diagram commutes.

So, this is the definition if you wish of a free abelian group, which says that there should be a map firstly from the set to the group f that map is γ such that given any other such map from the set to any other group that map factors through f , which is exactly how we express this fact that there is a unique map from F to N which makes the diagram commute. This may look like a slightly strange definition if you have seen other definitions of free groups before, but they are all the same sort of definitions.

(Refer Slide Time: 04:13)

Existence: $F = \left\{ h: S \rightarrow \mathbb{Z} : h(s) = 0 \text{ for all but finitely many } s \in S \right\}$

F is an abelian group under pointwise addition:

$$(h_1 + h_2)(s) = h_1(s) + h_2(s) \quad \forall s \in S$$

$$\begin{array}{ccc} & \gamma & \\ S & \xrightarrow{\gamma} & F \\ s & \mapsto & e_s \end{array}$$

$$e_s(x) = \begin{cases} 1 & \text{if } x=s \\ 0 & \text{otherwise} \end{cases}$$

So, first let us show using this definition why the free group exists and here the set S can be finite or infinite it does not matter. So, how do we prove existence of the free group on a set S .

So, let us construct the group. So, how shall we construct it? Well the set and the group F as a set is easy to describe. Let us take all functions from the given set S to the integers. It is just all functions, but well I do not want h to take non-zero values for infinitely in the S so I will say I

will put the conditions called finite support that h of S should be 0 for all but finitely many values of S .

Outside this finite set of finite subset of S for all the other values of S , h of S is 0. So, it is functions of finite support from the given set S to the integers. Now why is this group? So, firstly observe that F is an abelian group, so the claim is that F is an abelian group or a \mathbb{Z} -module under point wise addition.

In other words, how do you add two elements. So, if I give you h_1 plus h_2 two element of F you add them like this, the value on S is just $h_1(s)$ plus $h_2(s)$. This is for all s in S . So, this is a new function. Now the point is if h_1 and h_2 are 0 outside a finite set then, so is there point wise sum, why is that? Because look at the set of points on which h_1 takes a non-zero value, take the finitely many points on which h_2 takes an non-zero value, then h_1 plus h_2 can only take a non-zero value on the union of those two sets.

Outside the union it is definitely 0 and the union is definitely finite, because both, you take the union of two finite sets, it is finite again. So, the key point is that h_1 plus h_2 if you make this definition again it is a finitely non-zero function or a function of finite support.

Now let us understand this abelian group a little bit more. So, there are some special functions on this, so let me just call this for each S . So I have the following, so look at this, associated to each s there exists a map. I should say, let me construct this map from S to F first. So, to each S I have to associate a certain element of F , certain function and this is the function defined like this e_s the function on a given element of s it takes the value 1 if x equals s and 0 otherwise. So, this is the function, so sometimes called the indicator function of that point. It just takes the value 1 on just that single point S .

So, this is of course an element of F and now I have defined a map from S to F and this is going to be my map γ . Now observe that if I define these functions $e_s(x)$ in this manner then these are like the coordinate functions if you wish.

(Refer Slide Time: 08:33)

Observe: $h \in F \Rightarrow h = \sum_{s \in S} h(s) e_s$ (actually a finite sum)

Claim: (F, γ) is a free \mathbb{Z} -module on S

Pf: Need $\tilde{f} \circ \gamma = f$

$\tilde{f} \circ \gamma(s) = f(s) \quad \forall s \in S$

$\tilde{f}(e_s) = f(s) \quad \forall s \in S$

Also need \tilde{f} to be \mathbb{Z} -linear $\Rightarrow \tilde{f}(\sum h(s) e_s) = \sum h(s) f(s)$

Existence: $F = \{ h : S \rightarrow \mathbb{Z} : h(s) = 0 \text{ for all but finitely many } s \in S \}$

F is an abelian group under pointwise addition:

$(h_1 + h_2)(s) = h_1(s) + h_2(s) \quad \forall s \in S$

$e_s(x) = \begin{cases} 1 & \text{if } x=s \\ 0 & \text{otherwise} \end{cases}$

$S \xrightarrow{\gamma} F$
 $s \rightarrow e_s$

So, observe that every element of F I mean this is sort of from some sort of basis over \mathbb{Z} . So given any element of F implies h can be written as follows. It's h of e sub s . This is s running over S but really this is only a finite sum. This is actually only a finite sum because h is a function of finite support.

So, anything can be written as a linear combination. Any function can be written as a linear combination of the e s S . So, what all have you done so far? We had a set S . Now we have defined abelian group F and we have defined a map, set map from S to F . Now let us show that this in fact has the universal property that we need.

So, F is a free \mathbb{Z} -module on S . In other words, we need to show given any N and any function $f: S \rightarrow N$ I need to show that I can construct a unique group homomorphism from F to N which makes this diagram commute. So, let us prove this. So, what does the given condition satisfy? I mean what is the commuting of this diagram. So, sometimes we put this arrow to say that that diagram commutes. So what we need, we need the following property that $f \circ \gamma$ should be f . In other words, let us evaluate both sides on S for all elements s of S and what is this? This is $\gamma(s)$ we just defined.

If you go back and look γ was defined to be the map which takes each element s to the corresponding indicator function e_s . So, this $f \circ \gamma$ takes e_s to the value of f at s . So, this is what $f \circ \gamma$ must do. So, what does this imply? Well that tells you so if at all you can find such an $f \circ \gamma$ then that $f \circ \gamma$ has to satisfy this property.

And, so what is the other possibility. So, I mean what does that automatically imply and we also want $f \circ \gamma$ to be a group homomorphism. So, we need this property also need $f \circ \gamma$ to be a group homomorphism meaning it is a \mathbb{Z} -linear map. So, what does that mean? When $f \circ \gamma$ acts on a linear combination, so look at the linear combination that we wrote about, the answer will just turn out to be, I mean you can pull the scalars h of s outside.

And $f \circ \gamma(e_s)$ is just $f(s)$, so in some sense what this tells you is, if suppose such an $f \circ \gamma$ exists then we actually know what its formula is. It has to be given by this formula there is no other way out. So, it is definitely unique. The thing that remains to be proved is that this formula actually defines a group homomorphism. So, this is just sort of the initial heuristic motivation if you wish. So, now let us go ahead and define.

(Refer Slide Time: 12:10)

Define the map $\tilde{f}: F \rightarrow N$ as follows

$$h \mapsto \sum_{s \in S} h(s) f(s) \quad (\text{finitely many non-zero terms})$$

(1) $\tilde{f} \circ \gamma = f$

(2) \tilde{f} is \mathbb{Z} -linear:

$$\begin{aligned} \tilde{f}(h_1 + h_2) &= \sum_{s \in S} (h_1 + h_2)(s) f(s) = \sum_{s \in S} (h_1(s) + h_2(s)) f(s) \\ &= \sum_{s \in S} h_1(s) f(s) + \sum_{s \in S} h_2(s) f(s) = \tilde{f}(h_1) + \tilde{f}(h_2) \end{aligned}$$

So, let us define the map \tilde{f} from F to N as follows. Given any element of F I will map it to summation $\sum_{s \in S} h(s) f(s)$. This is s belonging to S and again observe that this sum has only finitely many non-zero terms. So, this is only finitely many non-zero terms, because the element h has only finite support.

So, that is my definition. So the claim is that this map is, so observe the following fact that \tilde{f} , this particular map certainly makes the diagram commute. In fact that is how we deduced what this formula should be, the key property to prove is that \tilde{f} is a group homomorphism. In other words it is \mathbb{Z} -linear.

So what does that mean? We need to show that if we take \tilde{f} and take a sum of two guys, h_1 plus h_2 we may see what the answer becomes, so it is h_1 plus h_2 evaluated at s times of $f(s)$ but h_1 plus h_2 is just the point wise sum. $h_1(s) + h_2(s)$ multiplied by $f(s)$ and this is now summation $\sum_{s \in S} h_1(s) f(s) + \sum_{s \in S} h_2(s) f(s)$, because well now here I am using the fact that all of these are elements in the \mathbb{Z} -module N . So, observe this is an element, I mean this is a scalar, this is an element of N . This part is an element of N of s .

So, what we are doing is now N is a \mathbb{Z} -module, so when a scalar multiply a sum of two scalars you have distributivity. So, I am using the fact that N is a \mathbb{Z} -module and so I have split it like this and now observe this is exactly $\tilde{f}(h_1)$ that is the first sum plus $\tilde{f}(h_2)$. In other words,

we have shown that f tilde is \mathbb{Z} -linear. So, what does that mean, it shows that, so it has shown the universal properties or claim has established. So, we have constructed the free module.

(Refer Slide Time: 14:59)

Observe: $h \in F \Rightarrow h = \sum_{s \in S} h(s) e_s$ (actually a finite sum)

Claim: (F, γ) is a free \mathbb{Z} -module on S

Pf: Need $\tilde{f} \circ \gamma = f$

$\tilde{f} \circ \gamma(s) = f(s) \quad \forall s \in S$

$\tilde{f}(e_s) = f(s) \quad \forall s \in S$

Also need \tilde{f} to be \mathbb{Z} -linear $\Rightarrow \tilde{f}(\sum h(s) e_s) = \sum h(s) f(s)$

So, the key point really is this, so if you remember what is a free module on the set S . It ((15:05)) elements of the set S form a basis for this module, basis over \mathbb{Z} in some sense and here that basis is really like the e_s if you think of the function e_s as being like a proxy for the element S . So, we have constructed the free module, again because it is a universal object we have the same principle as before. It becomes an initial object in the category suitably defined and so on. Like we discussed for tensor products.

But in more concrete terms it says that not only does the free abelian group exist, our existence proof shows it exists but then it is also unique, up to a unique isomorphism. In other words if I take another candidate F' , γ' then there will be an isomorphism from F to F' which makes this diagram commute and further that isomorphism is unique.

So, that is exactly the same discussion that we had earlier for the tensor products in the previous video and that also follows from the general discussion that you have seen because this is an initial object in a category. The initial object always has a unique map. I mean any two initial objects in a category are, there is a unique isomorphism from one to the other. So, now we have constructed one of these.

(Refer Slide Time: 16:43)

QUOTIENT Group : G group, H ^{normal} subgroup

Consider pairs (G_1, ϕ_1) where $\phi_1: G \rightarrow G_1$ hom st

$\ker \phi_1 \supseteq H$ & G_1 is a group

(Eg) $(G/H, \pi)$ where $\pi: G \rightarrow G/H$
 $g \mapsto gH$

$\ker \pi = H$

Now the second thing that I wanted to talk about in the terminology or context of universal properties is the notion of a quotient, the quotient group really. So this is, in fact this is even for non-abelian groups really, so if G is a group and H , suppose I fix these. H is a subgroup. Now what I am interested in is if you wish the category whose objects are going to be pairs, consider pairs, pairs what, of G 1, ϕ_1 where, what is ϕ_1 ? It is a map from G to G_1 such that the kernel of this map contains the fixed subgroup H , so we have fixed G and H here and I am looking at pairs and G is a group I should say, G_1 is a group.

ϕ_1 is a group homomorphism. This is a homomorphism such that. Now consider all such pairs, for example so there is one obvious such pair which is you can take G_1 to be, I mean the pair to be I should say normal subgroup. So, suppose H is a normal subgroup of this group G . Now let us look at one possibility, let us look at the quotient group $G \text{ mod } H$ and what is this map that I want to consider π .

So, consider the following pair for G_1 I will take $G \text{ mod } H$ and for this map ϕ_1 , I will take the projection map π , where what is π ? π is the obvious suggestion G to $G \text{ mod } H$ which takes every group element to its coset. This is the natural map from G to the quotient. Now this is of course one such example in fact in this case the kernel of this map π is exactly H .

So, it surely contains H . Now the point that I want to make in this setting is that this particular pair is actually also a universal object. This is also universal in the following sense. If you consider all such pairs G_1, ϕ_1 then the following is true.

(Refer Slide Time: 19:20)

Given (G_1, ϕ_1) as above i.e. $\ker \phi_1 \supseteq H$

\exists a unique group homomorphism $\tilde{\phi}_1: G/H \rightarrow G_1$ st

$\tilde{\phi}_1 \circ \pi = \phi_1$

Pf:

$\tilde{\phi}_1 \circ \pi(g) = \phi_1(g)$

$\tilde{\phi}_1(gH) = \phi_1(g)$

So, given G_1, ϕ_1 as above, meaning its kernel contains H then here is what I can say. So, here are two possible pairs but if the kernel of ϕ_1 contains H then there is always a map like this. So, this is ϕ_1 tilde then there exists a unique group homomorphism ϕ_1 tilde from $G \text{ mod } H$ to G_1 such that the diagram commutes.

Such that ϕ_1 tilde composition π is ϕ_1 . So, this is (20:19). So, let us prove it. It is rather straightforward. So, what do we want, we sort of know the commuting property the diagram should commute. This tells us something. It says that if I apply ϕ_1 tilde to π of g , the answer should be ϕ_1 of g .

In other words, ϕ_1 tilde acting on, what is π of g ? We just said it is the coset gH and of course this what should be the case if the diagram has to commute. So, we sort of know how to define this map ϕ_1 tilde. There is really only one choice. You must map the coset gH to the value ϕ_1 of G . So, this is like I said, like we did in the previous case. This is the sort of the heuristic motivation. It tells you what to do. And now you just have to check that if you actually do that then it is well defined group homomorphism. So, let us define.

(Refer Slide Time: 21:18)

$$\begin{aligned} \text{Define: } \tilde{\varphi}_1(gH) &:= \varphi_1(g) \\ \text{(i) Well-definedness: } g_1H = g_2H, \text{ need } \varphi_1(g_1) &= \varphi_1(g_2) \\ &\Updownarrow \\ g_2^{-1}g_1 &\in H \\ &\Downarrow \\ \varphi_1(g_2^{-1}g_1) &= e \text{ since } H \subseteq \ker \varphi_1 \\ \Rightarrow \varphi_1(g_2)^{-1} \varphi_1(g_1) &= e \Rightarrow \varphi_1(g_1) = \varphi_1(g_2) \end{aligned}$$

Now go ahead and define $\tilde{\varphi}_1$ as follows on the coset gH you define it to be φ_1 of g . So this is going to be a definition. Now the first thing whenever we define a map like this on coset is to ensure that this is well defined. That it does not depend on the representative that we have chosen for the coset.

So, you always have to check well definedness. Now what does that mean? It says that if the same coset has another representative so suppose g_1H and g_2H are both, g_1 and g_2 are two representatives for the same coset, then let us see what would have happened. If this is true you need to show that whether you use g_1 for your definition or g_2 for your definition the answers are the same.

So, φ_1 of g_1 should be the same as φ_1 of g_2 . This is what I need to prove, but let us see what do we know. g_1H equals g_2H is the same as saying in fact that $g_2^{-1}g_1$ belongs to H but remember H is contained in the kernel so in particular if I evaluate, since H is contained in the kernel.

So, I have used the property that is given to me and now I use the fact that φ_1 is a homomorphism, so it is φ_1 of $g_2^{-1}g_1$ is the identity. So, that is the same as saying φ_1 of g_1 equals φ_1 of g_2 . So, therefore it is well defined. So, I have checked the well definedness. I just need to check that it is a group homomorphism and that is easy. So, let us check.

(Refer Slide Time: 23:19)

$$\begin{aligned} \checkmark \quad \tilde{\varphi}_1(g_1 H \cdot g_2 H) &= \tilde{\varphi}_1(g_1 g_2 H) = \varphi_1(g_1 g_2) \\ &= \varphi_1(g_1) \varphi_1(g_2) \end{aligned}$$

$\Rightarrow \tilde{\varphi}_1$ is a group hom.

\mathcal{C} : objects: pairs (G_1, φ_1) where $\varphi_1: G \rightarrow G_1$
st $\ker \varphi_1 \supseteq H$.

arrows $G_1 \xrightarrow{\varphi_2} G_2$
 $\varphi_1 \downarrow \quad \nearrow \varphi$
 $G_1 \quad \varphi$
gp hom $\varphi: G_1 \rightarrow G_2$ st $\varphi \circ \varphi_1 = \varphi_2$

Given (G_1, φ_1) as above i.e. $\ker \varphi \supseteq H$

\exists a unique group homom

$\tilde{\varphi}_1: G/H \rightarrow G_1$ st

$$\tilde{\varphi}_1 \circ \pi = \varphi_1$$

Pf:

$$\left. \begin{array}{l} \tilde{\varphi}_1 \circ \pi(g) = \varphi_1(g) \\ \tilde{\varphi}_1(gH) = \varphi_1(g) \end{array} \right\} \Rightarrow \tilde{\varphi}_1 \text{ unique}$$

Phi 1 tilde, how do I check it is a group homomorphism? I take a product of two cosets. Well the product of two cosets if you remember is just the same as the coset of $g_1 g_2$, H is a normal subgroup and this is how you define the product of two cosets and now this by definition is just φ_1 of $g_1 g_2$, but φ_1 was a homomorphism to start with, so this φ_1 of $g_1 g_2$.

So, this means that φ_1 tilde is a group homomorphism. So, we have checked both the properties and uniqueness is of course true because of the way we, I mean this was the observation we made in the beginning. This argument implies that φ_1 tilde is unique, because the definition is forced upon us.

So, we have in fact shown all three parts. So, this is again you can think of this in terms of any initial object of a category and so on. You will have to define your category as follows. The objects are now pairs of, well what are they pairs of? Group and homomorphism. So, what is this? ϕ is now a homomorphism from the fixed given group G to the group G_1 such that its kernel contains the group H .

So, this is going to be, these are the objects and what are the morphisms or what are the arrows in this category? Well you have one such pair G_1 to G_2 and another, let put G_1 here and have G_2 here then, what is an arrow or morphism? Well it is a map, it is a homomorphism, let us call it ϕ , so an arrow by definition now is a group homomorphism ϕ from G_1 to G_2 , which makes the diagram commute. So this your, this is an arrow in this category. So, once you define your objects and arrows in this particular way.

(Refer Slide Time: 25:40)

$(G/H, \pi)$ is an initial object in \mathcal{C} .

Then observe again that the quotient that we are taking about $G/H, \pi$ is an initial object in this category \mathcal{C} . So, all these universal properties can be phrased in terms of initial or final objects in appropriate categories. Now we will use this next time to actually construct the tensor product of modules.
