Problem Session (Week 1)

1. If $\alpha = \sqrt[3]{2}$, find the irred. poly. of $1 + \alpha^2$ over \mathbb{Q} .

α satisfies $t^3 - 2$, $\mathbb{Q}(\alpha) = \mathbb{Q}[t]/(t^3 - 2)$, so $1, \alpha, \alpha^2$ are linearly indep over \mathbb{Q} .

$$1 = 1 = (1, 0, 0) \times 5$$

$$\gamma = 1 + \alpha^2 = (1, 0, 1) \times -3$$

$$\gamma^2 = 1 + 2\alpha^2 + \alpha^4 = (1, 2, 2) \times 3$$

$$= 1 + 2\alpha + 2\alpha^2$$

$$\gamma^3 = 1 + 3\alpha^2 + 3\alpha^4 + \alpha^6$$

$$= 1 + 3\alpha^2 + 6\alpha + 4 = (5, 6, 3)$$

$$= 5 + 6\alpha + 3\alpha^2$$

$\gamma^3 = 5 - 3\gamma + 3\gamma^2$
 So the irreducible polynomial
 $\gamma = 1 + \alpha^2$ is
 $t^3 - 3t^2 + 3t - 5$

Let us solve some problems. So here is the first problem, if alpha is the cube root of 2 find the irreducible polynomial of 1 plus alpha square over Q. So alpha is cube root of 2 then what we know is that the irreducible polynomial of alpha is t cube minus 2. Alpha satisfies t cube minus 2 and t cube minus 2 is clearly irreducible over Q because it has no roots over Q, a cubic polynomial cannot be irreducible unless it has root.

So alphas satisfies t cube minus 2 and so Q alpha is a just Q t mod t cube minus 2 which means that 1, alpha and alpha squared are linearly independent over Q. So with that in mind let say gamma is 1 plus alpha squared. We want to find a polynomial which, any irreducible polynomial that gamma satisfies. So the strategies for all these problems, so basically if you have a polynomial say gamma satisfies a polynomial like gamma to the 4 minus 3 gamma square plus 1 equals 0.

Then essentially this if you think of gamma, gamma squared, gamma cube and also 1 as elements of Q alpha then you can think of them as vectors and expand them in the basis 1 alpha and alpha square. And this kind of equation is a linear relation between those vectors. So idea is we start

with γ and we could even think 1 so that just 1 and we can think of this as vectors one we expand them to the 1 α and α^2 .

So we just compute some powers of γ and then look for the first time those vectors become linearly dependent. So in terms of the coordinates $1, \alpha, \alpha^2$ this is, this has $1, 0, 0$ coordinates, this has coordinates $1, 0, 1$. What about γ^2 ? Well it is $1 + 2\alpha + \alpha^2$. So this has coordinates well α to the power 4 , we know that $\alpha^3 = 2$ so this is $1 + 2\alpha + 2\alpha^2$.

So this has coordinates $1, 2, 2$ and let us look at γ^3 this has coordinates. So far this vectors look like they are linearly independent. If you take γ^3 now then we get that $\gamma^3 = 1 + 3\alpha + 3\alpha^2 + \alpha^3$ which is $3 + 3\alpha + 3\alpha^2$ so this is $3 + 6\alpha + 3\alpha^2$ and $\alpha^3 = 2$ so $\alpha^6 = 4$. So we get, I am sorry, $3\alpha^2$ is not 6 , it is just $3\alpha^2$.

α^2 is not 2 , $\alpha^3 = 2$ so what we get is $5 + 6\alpha + 3\alpha^2$. So this has coordinates $5, 6, 3$. So now we look at these 4 vectors they must have a linear dependence because they are vectors in \mathbb{Q}^3 . So let us just figure out, how to write γ^3 expand γ^3 in terms of $1, \gamma$ and γ^2 .

Now if you look at these coefficients here, so if you look at the second coordinate for example. So the second coordinate here is 2 , here it is 0 . So the only way, so we are looking for a relation of the form $a_1 + a_2\gamma + a_3\gamma^2 = \gamma^3$. So you look at the second coordinate the only possibility is that a_3 is 3 . So this has to be multiplied by 3 .

And once you do that this becomes 6 but now let us look at the third coordinate. So if I do 3 times this I get 6 here and so I have to subtract 3 times 1 to get 3 back. So I have to do this times minus 3 . And but then when I do that this 3 times 1 and minus 3 times 1 they cancel out and so to get 5 here I have to do 5 . So anyway one way or the other I find out that $\gamma^3 = 5 - 3\gamma + 3\gamma^2$. And so the irreducible polynomial of γ which is this $1 + \alpha^2 = t^3 - 3t^2 + 3t - 5$ and that is your solution.

(Refer Slide Time: 6:34)

$$\begin{aligned}
 & 2. \text{ Find the minimal polynomial of } \sqrt{3} + \sqrt{5} \text{ over } \mathbb{Q}. \\
 & \alpha := \sqrt{3} \notin \mathbb{Q}(\sqrt{5}) = \{a + b\sqrt{5} \mid a, b \in \mathbb{Q}\} \Rightarrow \{1, \alpha, \beta, \alpha\beta\} \text{ is lin. indep.} \\
 & \beta := \sqrt{5} \notin \mathbb{Q}(\sqrt{3}) \\
 & \gamma = 1 + \alpha^2 \quad \begin{array}{l} 1 = 1 \quad (1, 0, 0, 0) \cdot X - 4 \\ \gamma = \alpha + \beta \quad (0, 1, 1, 0) \\ \gamma^2 = 8 + 2\alpha\beta \quad (8, 0, 0, 2) \cdot X - 16 \\ \gamma^2 = 18\alpha + 14\beta \quad (0, 18, 14, 0) \\ \gamma^4 = 124 + 32\alpha\beta \quad (124, 0, 0, 32) \end{array} \\
 & \therefore \gamma^4 = 16\gamma^2 - 4 \\
 & \therefore \text{the irreducible poly. of } 1 + \alpha^2 \text{ is } \boxed{t^4 - 16t^2 + 4}.
 \end{aligned}$$

Here is the second problem. Find the minimal polynomial of square root 3 plus square root 5 over \mathbb{Q} . Before we jump into the calculation, let us just note that square root 3 does not belong to \mathbb{Q} adjoin square root 5. Because we know that this \mathbb{Q} adjoin square root 5 consists of complex numbers of the form a plus b root 5 where a and b are rational numbers. And it is not difficult to show, so if you have a number like this its square a plus b root 5 square is going to be a square plus $5b$ square plus $2ab$ root 5.

And if you want this square to be 3 then you would need either a to be 0 or b to be 0, in fact for the square to be rational number you would need either a to be 0 or b to be 0. Otherwise this $2ab$ root 5 term will come to haunt you. But if a is 0 or b is 0 then you cannot have, so if for example if a is 0 then you are looking at b root 5 squared which will be $5b$ squared but 3 is not a multiple of 5. So it cannot be that b root 5 squared is 3 and similarly of course a squared cannot be 3 because a is a rational number and square root of 3 is irrational.

So we know that square root 3 does not lie in \mathbb{Q} adjoin root 5 and very similarly we know that square root 5 does not lie in \mathbb{Q} adjoin root 3. What this means is that $1, \alpha$, so let us give this names, so let say α equals let us call this α square root 3 and β square root 5. So $1, \alpha$ of course these are linearly independent over \mathbb{Q} , 1 and β are linearly independent over \mathbb{Q} but α and β linearly independent because β is not in \mathbb{Q} root 3 in not in the field obtained by adjoining α to \mathbb{Q} .

And again $\alpha\beta$ is linearly independent of both α and β because α, β is neither in $\mathbb{Q}\sqrt{3}$ nor in $\mathbb{Q}\sqrt{5}$. It is not in $\mathbb{Q}\sqrt{3}$ because α is in $\mathbb{Q}\sqrt{3}$ but β is not in $\mathbb{Q}\sqrt{3}$. So α, β cannot be in $\mathbb{Q}\sqrt{3}$. So these are linearly independent. So this is linearly independent set and so now we take γ to be $1 + \alpha^2$ and just like last time we start computing powers of γ .

So and we expand those powers in terms of this basis. So firstly take the 0th power. So 1 is equal to 1 in terms of this basis it correspond to the vector $1, 0, 0, 0$. Now let us look at γ this is just $\alpha + \beta$. So this is the vector $0, 1, 1, 0$ in terms of this basis γ^2 is $\alpha^2 + \beta^2$ which is $8 + 2\alpha\beta$. So this corresponds to $8, 0, 0, 2$ in this basis.

And you can see so far this vectors are all linearly independent. And let us look at γ^3 for its $8 + 2\alpha\beta$ into $\alpha + \beta$. So what we get is, so let us just do it some rough work here $8 + 2\alpha\beta$ into $\alpha + \beta$ that works out to $8\alpha + 8\beta$. Now $2\alpha\beta$ into α is $2\alpha^2\beta$ but α^2 is 3, so that is 6β and $2\alpha\beta$ into β is $2\alpha\beta^2$ but β^2 is 5, so this becomes 10α .

So what we get here is that this is $18\alpha + 14\beta$. And this again see this vectors are very nice they either have non zero coordinates in the two middle coordinates as in γ and γ^3 or they have non zero coordinates in the first and last coordinates as in 1 and γ^2 . So it is very easy to see that this are linearly independent you just check that this vector and this vector are linearly independent, this vector and this vector are linearly independent, obviously all 4 of them are linearly independent.

What about γ to the power 4? So we have $18\alpha + 14\beta$ let us just use the space here to do the calculation. $18\alpha + 14\beta$ into $\alpha + \beta$. So what we get is $18\alpha^2 + 18\alpha\beta + 14\beta^2$. So α^2 is 3, so that is $54 + 14\beta^2$. So β^2 is 5, so 14 into 5 that is $70 + 18\alpha\beta + 14\alpha\beta$. So that is $18 + 14$ which is a $32\alpha\beta$.

So $54 + 70$ that is 124 . So we get $124, 0, 0, 32$ these are the first 5 powers of γ starting with γ to the power 0. And now we can find a linear dependence between these vectors. Now this γ to the power 4, we want to express it as a linear combination of 1 γ ,

gamma squared and gamma cubed. Well two middle coordinates of gamma to the power 4 are 0. So we only need to worry about, we will only use these two vectors in our expansion.

We will only use 1 and we will use gamma square and luckily for us here this coordinate is 0. So we know that this vector gamma squared must occur 16 times to get this. But if this occurs 16 time then here we have 8 into 16, what is 8 into 16 so 16 into 4 is (()) (13:15) 128. So we would have 124 minus 128, and so we would have to, we would have 128 so we would have to subtract 4. So this into minus 4 so what we get is, gamma to the power 4 equals 16 gamma square minus 4. Therefore, the minimal polynomial, the irreducible polynomial of 1 plus alpha squared is t to the power 4 minus 16 t squared plus 4 that is the solution.

(Refer Slide Time: 14:12)

3. Find the minimal polynomial of $\sqrt{3} + \sqrt{5}$ over $\mathbb{Q}(\sqrt{15})$.

$\gamma = 1 + \alpha^2$	$1 = 1$	$(1, 0, 0)$
	$\gamma = \alpha + \beta$	$(0, 1, 1)$
	$\gamma^2 = 8 + 2\alpha\beta$	$(3 + \sqrt{15}, 0, 0)$
	$\gamma^3 = 18\alpha + 14\beta$	$(0, 18, 14)$
	$\gamma^4 = 124 + 32\alpha\beta$	$(124, 0, 0)$

+

3. Find the minimal polynomial of $\sqrt{3} + \sqrt{5}$ over $\mathbb{Q}(\sqrt{15})$.

$$\begin{aligned} \gamma &= 1 + \alpha^2 & 1 &= 1 & (1, 0, 0) \\ \gamma &= \alpha + \beta & \gamma &= \alpha + \beta & (0, 1, 1) \\ \gamma^2 &= 8 + 2\alpha\beta & \gamma^2 &= 8 + 2\alpha\beta & (8 + 2\sqrt{15}, 0, 0) \end{aligned}$$

$$\gamma^2 = 8 + \sqrt{15}$$

Minimal polynomial of $\sqrt{3} + \sqrt{5}$ over $\mathbb{Q}(\sqrt{15})$ is
 $t^2 - (8 + 2\sqrt{15})$

2. Find the minimal polynomial of $\sqrt{3} + \sqrt{5}$ over \mathbb{Q} .

$\alpha := \sqrt{3} \notin \mathbb{Q}(\sqrt{5}) = \{a + b\sqrt{5} \mid a, b \in \mathbb{Q}\}$
 $\beta := \sqrt{5} \notin \mathbb{Q}(\sqrt{3})$ } $\Rightarrow \{1, \alpha, \beta, \alpha\beta\}$ is lin. indep.

$$\begin{aligned} \gamma &= 1 + \alpha^2 & 1 &= 1 & (1, 0, 0, 0) - x - 4 \\ & & \gamma &= \alpha + \beta & (0, 1, 1, 0) \\ & & \gamma^2 &= 8 + 2\alpha\beta & (8, 0, 0, 2) - x^2 - 16 \\ & & \gamma^3 &= 18\alpha + 14\beta & (0, 18, 14, 0) \\ & & \gamma^4 &= 124 + 32\alpha\beta & (124, 0, 0, 32) \end{aligned}$$

$$\therefore \gamma^4 = 16\gamma^2 - 4$$

\therefore the irreducible poly. of $1 + \alpha^2$ is $t^4 - 16t^2 + 4$.

Now I am going to take the previous problem and change it just a little bit firstly instead of problem 2 I am going to call it problem 3 and instead of finding the minimal polynomial of root 3 root plus 5 over \mathbb{Q} , I am going to ask for the minimal polynomial of root 3 plus root 5 over \mathbb{Q} square root of 15. Now this is actually our old alpha beta. So alpha beta is no longer, is no longer linearly independent of 1 and alpha and beta because alpha beta is already in the field.

So alpha beta is a scalar, so what we do is we go back to the previous problem and we look at this powers but now what we have is alpha beta is over here. So let me just, let me just copy this whole thing and bring it over to the next slide. So this are the calculations in \mathbb{Q} but now this

alpha beta is part of the first coordinate. So we no longer have this third coordinate. And this rather fourth coordinate and so what we are saying is that this is 1, 0, 0.

This is well still alpha plus beta but this was a 8 plus 2 alpha beta. So what we get is here we would write 8 plus root 15 because now that is in the field. But this gamma squared is already now a scalar multiple of 1, 0, 0. So this two steps we do not need at all. So we do not need this bit here. So we will just remove it and so what we get is gamma squared.

Since we are working over $\mathbb{Q} \sqrt{15}$, we get gamma squared is 8 plus root 15 and so what we have is that the minimal polynomial of root 3 plus root 5 over $\mathbb{Q} \sqrt{15}$ is t square minus 8 plus root 15 and that is the solution. I am sorry this should be I think there was a 2 there right? yeah that is a 2, so there should be 2 root 15. 8 plus 2 root 15 and so this should be 8 plus 2 root 15 and that is the solution to our problem.

(Refer Slide Time: 17:37)

4. Let $\zeta_n = e^{2\pi i/n}$ (primitive n th root of unity)
 Determine $[\mathbb{Q}(\zeta_n) : \mathbb{Q}]$ for $n=1, 2, 3, 4, 5, 6$.

$\zeta_1 = 1$, $[\mathbb{Q}(\zeta_1) : \mathbb{Q}] = 1$
 $\zeta_2 = -1$, $[\mathbb{Q}(\zeta_2) : \mathbb{Q}] = 1$
 $\zeta_3 = e^{2\pi i/3}$ satisfies $(t^3-1) = (t-1)(t^2+t+1)$ *irreducible*
 $[\mathbb{Q}(\zeta_3) : \mathbb{Q}] = 2$
 $\zeta_4 = e^{2\pi i/4}$ satisfies $(t^4-1) = (t-1)(t+1)(t^2+1)$ *irreducible*
 $[\mathbb{Q}(\zeta_4) : \mathbb{Q}] = 2$

Now come to problem 4 which is a very interesting class of a numbers was minimal polynomial we shall seek. Let zeta n be e to the power 2 pi i by n. So this is a complex number and if you raise this number to the power n then you get 1. So this is, this is called a primitive nth root of unity. The powers of this number are all the nth roots of unity in the complex number. All the numbers which if you raise the power to n you get 1.

And a very interesting problem is to determine the degree $\mathbb{Q} \zeta_n$ over \mathbb{Q} for, well you so this is known for all n but today we will just do n equals 1, 2, 3, 4, 5, 6. So we will try this, we may not

succeed in solving all of them but what we know right now. So let us give it a shot. So what is zeta 1, so zeta 1 is just 1 it is a rational number. So $\mathbb{Q}(\zeta_1)$ over \mathbb{Q} has degree 1. In fact, the minimal polynomial the irreducible polynomial of zeta 1 is just $t - 1$.

Zeta 2 is minus 1 again it is rational, so $\mathbb{Q}(\zeta_2)$ over \mathbb{Q} is equal to 1. What about zeta 3? So zeta 3 turns out to be a well $e^{2\pi i/3}$ it is a cube root of unity. So it satisfies the polynomial $t^3 - 1$ which is $(t - 1)(t^2 + t + 1)$. But of course we know that $t - 1$ does not vanish at zeta 3. So $t^2 + t + 1$ must vanish at zeta 3. And $t^2 + t + 1$ is irreducible over \mathbb{Q} . So this must be the irreducible polynomial of zeta 3.

And so this part is irreducible and satisfy and vanishes at zeta 3. So what we get is that $\mathbb{Q}(\zeta_3)$ over \mathbb{Q} is just 2, this is the irreducible polynomial. Let us look at zeta 4. So zeta 4 is a $e^{2\pi i/4}$ which we also know to be the number i . The square root of minus 1 and this satisfies $t^4 - 1$ which I can write as $(t - 1)(t + 1)(t^2 + 1)$. Now this factors do not vanish at zeta 4.

So we are only left with this factor and this is irreducible again. So for quadratic polynomials easy to check that they are irreducible, you just use the formula for the root of a quadratic polynomial the discriminant is negative then they are irreducible. So this is irreducible and so again we get $\mathbb{Q}(\zeta_4)$ over \mathbb{Q} is equal to 2.

(Refer Slide Time: 21:26)

$\zeta_5 = e^{2\pi i/5}$ satisfies $(t^5 - 1) = (t - 1)(t^4 + t^3 + t^2 + t + 1)$.
 $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = 4$ irred. (to be done)

$\zeta_6 = e^{2\pi i/6}$ satisfies $(t^6 - 1) = (t - 1)(t^3 + 1)(t^3 + 1)$.
 $[\mathbb{Q}(\zeta_6) : \mathbb{Q}] = 3$. irred.

4. Let $\zeta_n = e^{2\pi i/n}$ (primitive n th root of unity)

Determine $[\mathbb{Q}(\zeta_n) : \mathbb{Q}]$ for $n=1, 2, 3, 4, 5, 6$.

$$\zeta_1 = 1, \quad [\mathbb{Q}(\zeta_1) : \mathbb{Q}] = 1$$

$$\zeta_2 = -1, \quad [\mathbb{Q}(\zeta_2) : \mathbb{Q}] = 1$$

$$\zeta_3 = e^{2\pi i/3} \text{ satisfies } (t^3 - 1) = (t-1)(t^2 + t + 1)$$

$$[\mathbb{Q}(\zeta_3) : \mathbb{Q}] = 2$$

$$\zeta_4 = e^{2\pi i/4} \text{ satisfies } (t^4 - 1) = (t-1)(t+1)(t^2 + 1)$$

$$[\mathbb{Q}(\zeta_4) : \mathbb{Q}] = 2$$

irreducible

irreducible

And now let us go to zeta to the power 5. So zeta power 5 is $e^{2\pi i/5}$ and this satisfies $t^5 - 1$ which I can write as $(t-1)(t^4 + t^3 + t^2 + t + 1)$. Now $t^4 + t^3 + t^2 + t + 1$ sorry there is one more term missing plus $t^4 + t^3 + t^2 + t + 1$. And well it turns out that this polynomial is irreducible but showing that it is irreducible may not be that easy I will differ it to next week.

And the you will see this when we through Eisenstein criterion for irreducibility but anyway it turns out that this guy is irreducible. And in any case zeta 5 does not satisfy this. So this, so this is to be done. So we have not technically fully solved this problem you can try it proving that it is irreducible with how much you know right now like by looking for a factorization. We know it has no roots but we need to know that it does not have any quadratic factor.

So you can try to do that with your bare hands comes out more easily where the Eisenstein criteria. So this needs to be shown to be irreducible. But then if we accept the fact that is irreducible then what we get is $\mathbb{Q}(\zeta_5) : \mathbb{Q}$ has degree 4. Because this polynomial is of degree 4. Interesting one zeta 6 $e^{2\pi i/6}$. So this satisfies $t^6 - 1$ and this has a nice factorization.

So it is a $t^3 - 1$ into $t^3 + 1$ but $t^3 - 1$ is $(t-1)(t^2 + t + 1)$ plus 1. And then there is another thing which is $t^4 + t^3 + t^2 + t + 1$, no that is just $t^3 + 1$. So these two give $t^3 - 1$ and this is $(t-1)(t^2 + t + 1)$, $t^3 - 1$ into $t^3 + 1$.

cube plus 1 is t cube minus 6. Now this does not vanish at zeta 6, this also does not vanish at zeta 6 we know what its roots are, its roots are zeta 3, zeta 3 squared.

So this does not vanish at zeta 6, so this must be, so this polynomial vanishes at zeta 6. And this polynomial is irreducible again for cubic polynomial we know it is irreducible if it does not have a root. So this guy is irreducible and so what we get is that the degree of Q zeta 6 over cube is equal to 3. So we have an interesting sequence here 1, 1, 2, 2, 4 and 3. See if you can guess what the pattern is, this is a very important class of field extensions, these are the cyclotomic extensions and we will keep revisiting them during this course.

(Refer Slide Time: 25:03)

5. Prove that a regular pentagon can be constructed using a straightedge and compass.

$\zeta_5 = e^{2\pi i/5}$

Need to show that ζ_5 is constructible.

ζ_5 satisfies $t^4 + t^3 + t^2 + t + 1$ over \mathbb{Q} .

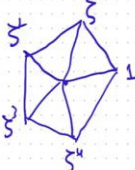

ζ_5 is constructible iff $\exists F \ni \mathbb{Q}(\zeta_5)$

|₂

F

|₂

\mathbb{Q}

A last problem, prove that a regular pentagon can be constructed using a straightedge and compass. Now you can construct a regular pentagon if you can construct a fifth root of unity. So like zeta 5 as before the e to the 2 pi i by 5 and if you can show that this point is constructible then its powers will also lie in the same field Q adjoins zeta 5 and you can realize a regular pentagon as having corners of given by the, so if I draw a regular. It is not a great drawing but straight in through it a bit.

That is the best I can do. So this is 1, this is zeta, this is zeta squared, this is zeta cubed and this is zeta power 4. And these will all have the same angle related to each other at the center. So this will be a regular pentagon, so we just need to show that we can construct the point zeta is

constructible. And then its powers will automatically be constructible by our criterion for constructability.

So we need to show that a zeta 5 is constructible. Well we have already seen that zeta 5 probably has degree 4 over Q. It satisfies a polynomial of degree 4 at any date. So let us just see that, so in fact we have a zeta 5 satisfies $t^4 + t^3 + t^2 + t + 1$ over Q. And to show that it is, so the degree of zeta 5 is 4 Q, Q adjoint zeta 5 is probably 4 well we have not quite prove that but it become clear by the time I solve this problem.

So what we have is this, you have this Q zeta 5, zeta 5 does not satisfies any quadratic polynomial over Q. So what we are asking is, you know can we find a field here F between Q zeta 5 and Q such that F is of degree 2 over Q and Q zeta 5 is of degree 2 over F. So zeta 5 is constructible if and only if we can find this. F such that this holds, i. e., F lies between Q zeta 5 and Q and F is degree 2 over Q and Q zeta 5 is degree 2 over F.

So we are looking for this kind of a field. So in these fields since this is the quadratic equation zeta 5 would satisfy a quadratic polynomial over F. So what we would try to do is take this polynomial of degree 4 and see if we can write it as a product of two quadratic polynomials over some intermediate field.

(Refer Slide Time: 28:21)

$$\begin{aligned} \text{Suppose: } t^4 + t^3 + t^2 + t + 1 &= (t^2 + \alpha t + 1)(t^2 + \beta t + 1) \\ &= t^4 + (\alpha + \beta)t^3 + (2 + \alpha\beta)t^2 + (\alpha + \beta)t + 1 \\ \text{Need: } \alpha + \beta &= 1, \quad 2 + \alpha\beta = 1 \\ &\Downarrow \\ &\beta = -\alpha^{-1} \end{aligned}$$

$$\begin{aligned} \text{So } \alpha - \alpha^{-1} &= 1 \\ \text{or } \alpha^2 - \alpha - 1 &= 0 \Rightarrow \alpha = \frac{1 + \sqrt{5}}{2}, \quad \beta = \frac{1 - \sqrt{5}}{2} \\ (t^4 + t^3 + t^2 + t + 1) &= \left(t^2 + \frac{1 + \sqrt{5}}{2}t + 1\right) \left(t^2 + \frac{1 - \sqrt{5}}{2}t + 1\right) \end{aligned}$$

ζ_5 satisfies $t^2 \pm 1 + \sqrt{5}$

So we would have to have factorize $t^4 + t^3 + t^2 + t + 1$ and we want to factorize this we would have two quadratic factors. And let us just try this

with $t^2 + \alpha t + 1$ and $t^2 + \beta t + 1$. Let us try to find a factorization like this. And α, β need not be rational numbers, they just need to lie in a quadratic extension of \mathbb{Q} .

So if we expand this, what we get is t^4 then the coefficient of t^3 is $\alpha + \beta$ and then the coefficient of t^2 is $2 + \alpha\beta$. And then the coefficient of t is $\alpha + \beta$ and then $+1$. So what we need to is $\alpha + \beta = 0$ and $2 + \alpha\beta = 1$. Well $\alpha + \beta = 0$ is the same as saying that $\beta = -\alpha$.

And substituting that in here we have $\alpha - \alpha^{-1} = 0$ multiplying by α and bringing everything to the left hand side, we get $\alpha^2 - 1 = 0$. Which means that α has to be 1 or -1 . $1 + \sqrt{5}$ over 2 is the golden ratio. This is a very famous quadratic equation and well so β , so maybe we can take α to be $1 + \sqrt{5}$ over 2 .

And we can take β to be $1 - \sqrt{5}$ over 2 and you will find that all your conditions are satisfied. So what we get is $t^4 + t^3 + t^2 + t + 1$ is equal to $(t^2 + 1 + \sqrt{5}/2)t + 1$ and $(t^2 + 1 - \sqrt{5}/2)t + 1$. So what we have is now the field generated by $1 + \sqrt{5}/2$ contains $1 - \sqrt{5}/2$ and the field generated by $1 - \sqrt{5}/2$ contains $1 + \sqrt{5}/2$.

These are the same field and so what we have is that ζ_5 satisfies the quadratic equation $t^2 + 1 = 0$ over $\mathbb{Q}(\sqrt{5})$. So maybe it satisfies one of these over $\mathbb{Q}(\sqrt{5})$. So that is our intermediate field $\mathbb{Q}(\sqrt{5})$.

(Refer Slide Time: 31:51)

$$\begin{array}{c} \text{Have } \mathbb{Q}(\zeta_5) \\ | 2 \\ \mathbb{Q}(\sqrt{5}) \\ | 2 \\ \mathbb{Q} \end{array}$$

So ζ_5 is constructible.
Hence a regular pentagon is constructible.

So we have $\mathbb{Q}(\zeta_5)$ lies over $\mathbb{Q}(\sqrt{5})$ and $\mathbb{Q}(\sqrt{5})$ lies over \mathbb{Q} and each of this is of degree 2. And so ζ_5 is constructible, it is a constructible point and hence a regular pentagon is constructible. Now it could be an interesting project for you to take this idea and try to translate it into an actually straightedge and compass construction for a regular pentagon. I hope you have fun doing that but I will just leave you with this challenge as for now.
