Completion

(Refer Slide Time: 00:23)

Completion of a normed vector space.

NPTEL

V - Normed vector space
 x_n - Cauchy s.e. there is no limit.

Lemma: Let V be a normed v.s. and
 $x_n \in V$ be a Cauchy sequence.
Then $\|x_n\|$ converges.

Proof: It is immediate from
$$| \|x_n\| - \|x_m\| | \leq \|x_n - x_m\|.$$

In this video I am going to sketch a proof of how we can start with the normed vector space and construct a complete normed vector space that in some sense contains the normed vector space we started off with. This essentially shows that any normed vector space can be completed. In particular, the construction I am about to sketch can be used to start with \mathbb{Q} and get \mathbb{R} . The basic idea of how you go from \mathbb{Q} to \mathbb{R} and how you complete a normed vector space are quite similar.

So, the situation we are in is, we have a normed vector space V , but it could possibly be incomplete. What that means is, there could be a Cauchy sequence x_n in V , such that there is no limit.

So the question is we have to somehow add points to the vector space V in order to make sure that every Cauchy sequence converges to a point in V . Now, what is that point you would add corresponding to this Cauchy sequence which is not converging? Well, what could be more natural when representing that particular point that we need to add by the Cauchy sequence itself.

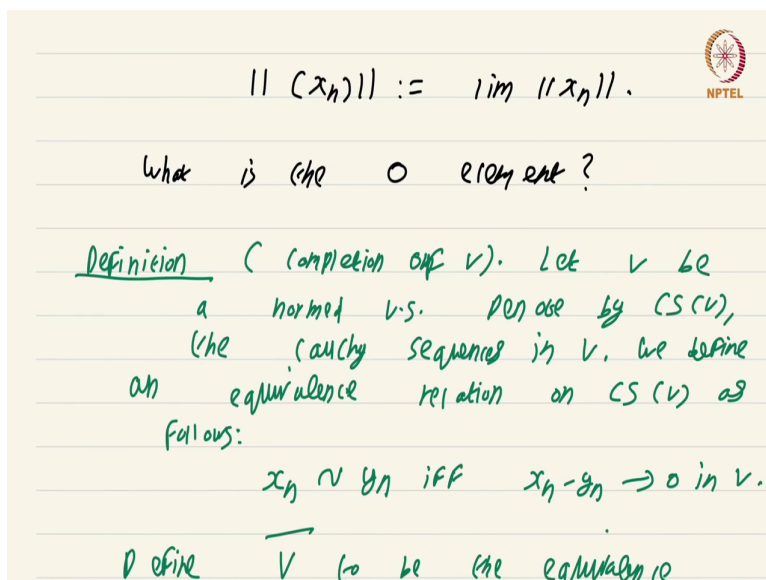

So this might seem like an extremely bizarre way of doing it, but if you think about it for a moment, it is extremely natural. We need to complete it by adding points and these points correspond to Cauchy sequences in the original space V that do not converge. Therefore, we add that Cauchy sequence itself as the limit.

Now, one issue that might arise is that there are many Cauchy sequences that converge to the same point. If you had a vector space V , normed vector space V , there could be multiple Cauchy sequences, that could converge to the same point.

Furthermore, we need to sort of define a norm for this point that we are adding. So, let us do this step by step. First, let us take care of the norm by the simple lemma. Let V be a normed vector space, normed vector space and x_n in V be a Cauchy sequence. Then $\|x_n\|$ converges.

So the proof of this is a rather trivial. This proof immediately follows. Proof it is immediate from absolute value of $\|x_n\| - \|x_m\|$ is less than or equal to $\|x_n - x_m\|$. From this it is immediate that this sequence $\|x_n\|$ is a Cauchy sequence and therefore, it must converge because \mathbb{R} is complete.

(Refer Slide Time: 03:52)

$$\| (x_n) \| := \lim \| x_n \|.$$

What is the 0 element?

Definition (completion of V). Let V be a normed v.s. denote by $CS(V)$, the Cauchy sequences in V . We define an equivalence relation on $CS(V)$ as follows:

$$x_n \sim y_n \text{ iff } x_n - y_n \rightarrow 0 \text{ in } V.$$

Define \overline{V} to be the equivalence

So, what this lemma suggests is that once you add these Cauchy sequences, let us suppose you denote I mean you going you are going to essentially define the norm of this Cauchy sequence to be nothing but limit of norm x_n ok. That is what this lemma suggests.

Now, another question we have this new vector space V that has some bizarre elements, they are Cauchy sequences, what is the 0 element, what is the 0 element? Ok. Now, the 0 element should correspond to Cauchy sequences that converge to 0, but they are many of them and which one do you choose.

Well, we are going to choose in some sense all of them. So, let me now formally state the definition of the completion and I will sketch a proof that this definition is in fact makes sense. I mean, I am going to define various things and they may not be well defined. I will

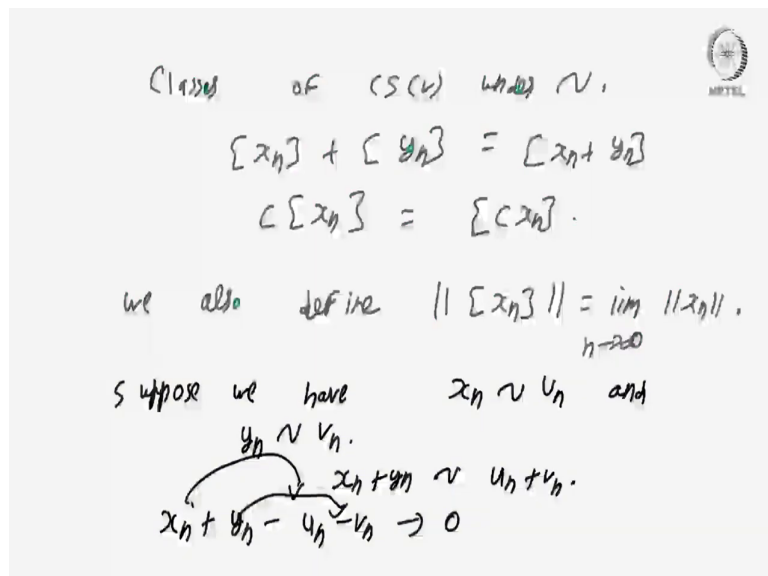

sketch a proof that all the things that I am claiming are well defined are in indeed well defined, completion of V ok.

So, the setup is let V be a normed vector space, normed vector space denote by CS of V the Cauchy sequences the Cauchy sequences in V . So, what we are doing is we are taking all the Cauchy sequences and putting it inside a basket and calling that basket CS of V .

Now as we have observed there are multiple Cauchy sequences that converge to the same point. So, we need to identify certain Cauchy sequences and the perfect way to do it is to use equivalence relations. We define an equivalence relation on CS V as follows. The sequence x_n is related to the sequence y_n if and only if $x_n - y_n$ converges to 0 in V ok.

The fact that this is a Cauchy sequences, I mean the fact that this is an equivalence relation is utterly trivial, so I am not even going to bother mentioning that anymore ok.

(Refer Slide Time: 06:38)

Class of $CS(V)$ under \sim .

$$[x_n] + [y_n] = [x_n + y_n]$$

$$c[x_n] = [cx_n].$$

we also define $\|[x_n]\| = \lim_{n \rightarrow \infty} \|x_n\|$.

Suppose we have $x_n \sim u_n$ and $y_n \sim v_n$.

$$x_n + y_n \sim u_n + v_n.$$

$$x_n + y_n - u_n - v_n \rightarrow 0$$

Now, the crucial definition. Define the completion of V which I am going to denote by V closure as a nice mnemonic. Define V closure to be the equivalence classes the equivalence classes of $CS V$ under this equivalence relation ok.

Now, I am going to denote a equal an equivalence class like this ok. Now, we need to define, we need to define the operations under $CS V$ that make it a vector space and those operations are rather straightforward. We define the equivalence class of x_n plus the equivalence class of y_n to be as you can guess x_n plus y_n the equivalence class of x_n plus y_n .

Similarly, scalar multiplication is dealt with in an exact same way. The equivalence class of C times, I mean the element corresponding to C times the equivalence class of x_n is nothing but

the equivalence class of $C \times \mathbb{N}$ ok. We also define we also define we also define the norm of x_n in the equivalence class of x_n to be $\lim_{n \rightarrow \infty} \|x_n\|$, n going to infinity ok.

Now, there are number of trivial checks that need to be done to ensure that we have not done anything illegal in this definition ok. The fact that it is an equivalence class is trivial I am going to leave it to you. First, we have to show that these operations that we have defined $x_n + y_n$ and $C \times x_n$, they are independent of the representative.

So, suppose we have, suppose we have x_n is related to u_n and y_n is related to v_n ok. Suppose we have we are taking two distinct representatives of the single equivalence class box x_n . Now we have to show that the output that you get this $x_n + y_n$ actually no necessity to put a box. We have to show that this $x_n + y_n$ is related to $u_n + v_n$. That will show that our operation is independent of the choice of representative.

But that is easy because $x_n + y_n - u_n - v_n$ converges to 0, because $x_n - u_n$ and $y_n - v_n$ converges to 0. Therefore, $x_n + y_n - u_n - v_n$ converges to 0. So, the addition operation at least is independent of the choice of representatives. In an exactly similar way, we can check that the scalar multiplication is also independent of the choice of representative.

(Refer Slide Time: 09:39)

showing \bar{V} is a v.s. is just a long but easy check. 

$$\| \{x_n\} \| = 0 \Leftrightarrow \|x_n\| \rightarrow 0$$
$$\Leftrightarrow x_n \rightarrow 0 \Leftrightarrow \{x_n\} = 0.$$
$$\| c \{x_n\} \| = |c| \| \{x_n\} \|.$$
$$\| \{x_n\} + \{y_n\} \| = \| \{x_n + y_n\} \|$$
$$\lim \|x_n + y_n\| \leq \lim \|x_n\| + \lim \|y_n\|$$
$$= \| \{x_n\} \| + \| \{y_n\} \|.$$

Now, once you have these operations, showing this \bar{V} closure is a vector space is just a long but easy check. You have to check each and every one of the stupid axioms of a vector space ok. So, we have at least constructed a vector space of Cauchy sequences or rather equivalence classes of Cauchy sequences.

We have defined a norm, we have to now check that, in fact this is a norm. So again, these are all straightforward easy checks, let me just do a few of them. Suppose, you have that the norm of a particular equivalence class is 0 ok. Now this will happen if and only if $\|x_n\|$ converges to 0, because that is how that is how the norm in this complicated space of equivalence classes was defined.

You just take $\|x_n\|$ and take limit n going to infinity. Now this will happen if and only if $\|x_n\|$ converges to 0 right, and this will happen if and only if $\{x_n\} = 0$. So, this chain of

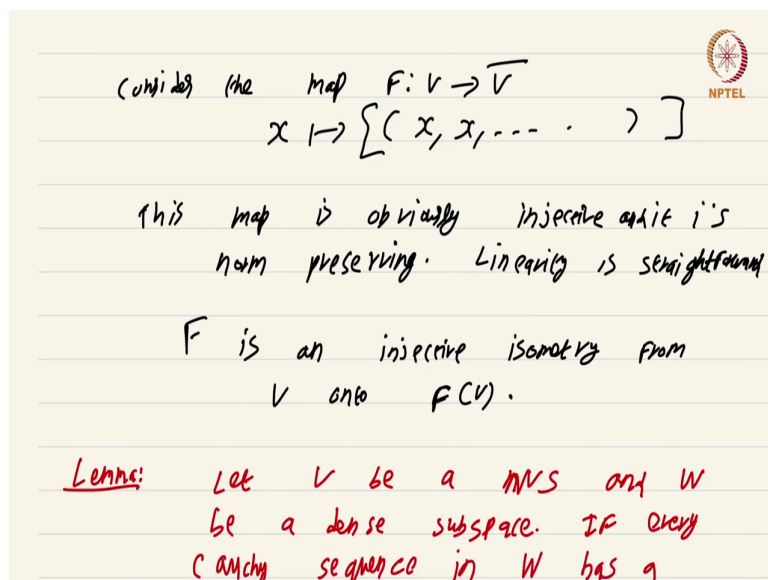

equivalences proves that the norm of an element in our bizarre space \bar{V} is 0 if and only if the representative, that is x_n itself is 0 ok.

Now, similarly you can show that I mean it is rather easy to show that norm of Cx_n is equal to $|C|$ norm of x_n and this is an easy check ok. Now coming to the triangle inequality what we have to do is, we have to consider norm of $x_n + y_n$, but the operation means that this is nothing but norm of $x_n + y_n$ ok. Which is nothing, but $\lim \|x_n + y_n\|$.

That is the definition of the norm in this vector space, which is less than or equal to $\lim \|x_n\| + \lim \|y_n\|$, by the triangle inequality which is equal to norm of x_n plus norm of y_n .

So, this shows that the triangle inequality is satisfied by our definition of norm on the space \bar{V} ok.

(Refer Slide Time: 12:27)

consider the map $F: V \rightarrow \overline{V}$
 $x \mapsto [x, x, \dots]$

this map is obviously injective and it's
norm preserving. Linearity is straightforward.

F is an injective isometry from
 V onto $F(V)$.

Lemma: Let V be a NKS and W
be a dense subspace. If every
Cauchy sequence in W has a

Now, consider the map consider the map, F from V to \overline{V} ok, and the map is given by x maps to as you can guess the constant Cauchy sequence x, x, x, x, x . I should put a box around it for it for the definition to be 100 percent precise.

Now, this map is obviously injective. This map is obviously injective and it is equally obvious that it is and it is norm preserving that is the norm of x is the same as norm of box of x which is obvious ok. Linearity is straightforward. Linearity is also straightforward. I want you to do it, it is just a 30 second check ok.

So what this shows, is that this map F is an injective isometry from V onto $F(V)$ ok. So, what this shows is that V is sitting inside \overline{V} as an isometrically embedded copy. So essentially, we have extended the space V to this larger space \overline{V} or V closure or whatever

you want to call it and V is sitting in there exactly as a copy that is in the guise of F of V in a different disguise. It is sitting in there as F of V .

Now, we still have to show that this bizarre space V bar is actually a complete normed vector space and that is going to be taken care of by the next lemma. The next lemma relates density and completeness ok. What it says is the following; let V be a normed vector space. I am just going to abbreviate it as NVS and W be a dense subspace.

So, it is a subspace of V whose closure is equal to V ok. If every Cauchy sequence every Cauchy sequence in W has a limit in V , then V is complete.

(Refer Slide Time: 15:13)

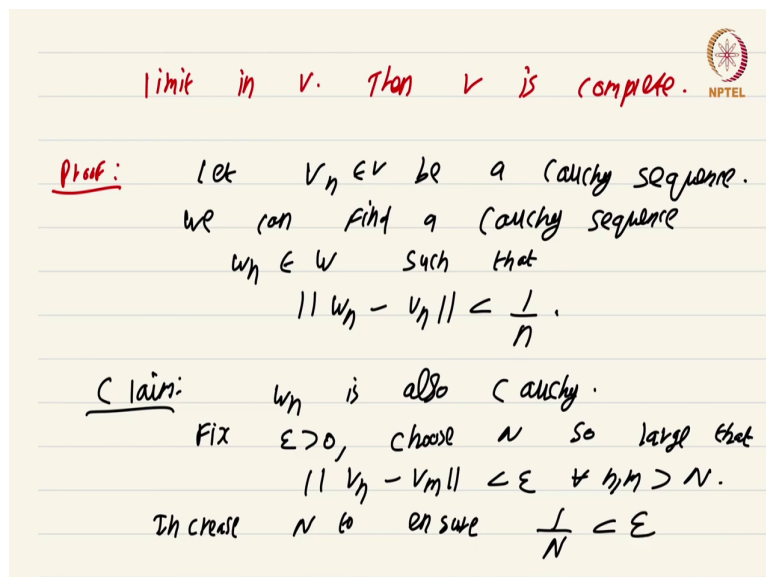

limit in V . Then V is complete. 

Proof: let $x_n \in V$ be a Cauchy sequence.
we can find a Cauchy sequence
 $w_n \in W$ such that
$$\|w_n - x_n\| < \frac{1}{n}.$$

So, the setup is as follows; we have a normed vector space V , and W is a dense subspace. If every Cauchy sequence in W has a limit not necessarily in W , but in V then V is actually complete ok.

So, the proof is again not so difficult. Let x_n in V be a Cauchy sequence. We have to show that this sequence has a limit in V . Now, because W is dense in V , we can find we can find a Cauchy sequence w_n in W , such that norm of w_n minus x_n is less than $1/n$ ok. Now, if you want if you want to show that ok.

(Refer Slide Time: 16:40)

limit in V . Then V is complete. NPTEL

Proof: Let $x_n \in V$ be a Cauchy sequence.
 We can find a Cauchy sequence
 $w_n \in W$ such that

$$\|w_n - x_n\| < \frac{1}{n}.$$

Claim: w_n is also Cauchy.
 Fix $\epsilon > 0$, choose N so large that

$$\|x_n - x_m\| < \epsilon \quad \forall n, m > N.$$

 Then choose N to ensure $\frac{1}{N} < \epsilon$

Just a second, I sort of made a slight mistake, let us just call this x_n for convenience, because I have use x_n later, in the beginning I said x_n . So that makes no sense ok.

So, if you want to show that V_n is convergent, we use the fact that whenever you have a Cauchy sequence in W it converges. So, what we are trying to do is we are trying to construct a Cauchy sequence W_n in W , which would converge to the same point that V_n would converge to, but W_n must necessarily converge therefore, V_n must also converge that is the basic logic ok.

Now, to do this we have to first claim W_n is also Cauchy ok. Now, how do you see this well fix ϵ greater than 0 choose capital N , so large that $\|V_n - V_m\| < \epsilon$ for all n, m greater than capital N . This is of course possible because V_n is a Cauchy sequence. Increase N to ensure $1/N$ is also less than ϵ ok.

(Refer Slide Time: 18:05)

then

$$\|w_n - w_m\| \leq \|v_n - w_n\| + \|v_m - w_m\| + \|v_n - v_m\| < 3\epsilon$$

if $n, m > N$

claim

Suppose $w_n \rightarrow v \in V$, $v_n \rightarrow v$

fix $\epsilon > 0$ and choose N so large

that if $n > N$ then

$$\|w_n - v\| < \epsilon \quad \text{and}$$

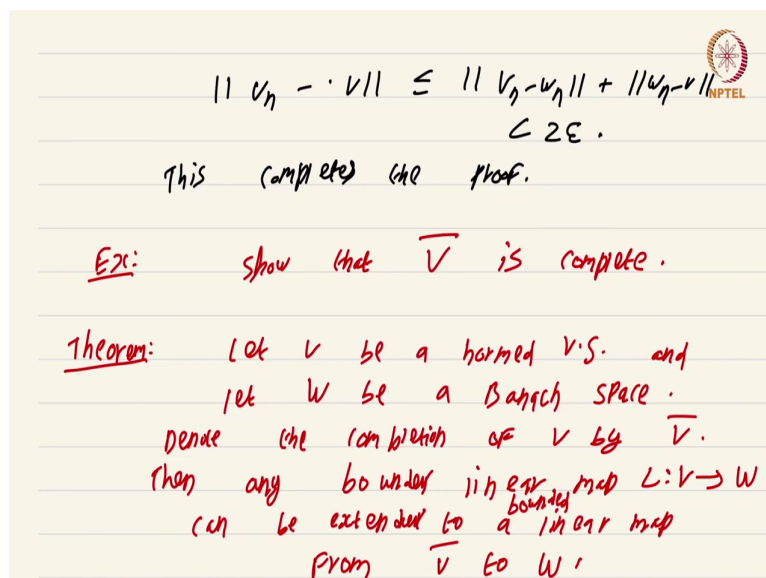

$$\|w_n - v_n\| < \epsilon$$

Then, observe that $\|w_n - w_m\|$ is by the triangle inequality less than $\|v_n - w_n\| + \|v_m - w_m\| + \|v_n - v_m\|$. So, this is the three epsilon trick which we have

done so many times and this is going to be less than or equal to 3ϵ if n comma m is greater than N . In fact, this is going to be less than there is no need to write less than or equal to ok.

So, this proves that W_n is a Cauchy sequence. So, suppose W_n converges to V in V . By hypothesis there will be an element in V that converge that is the limit of W_n . Now the claim is that V_n also converges to V . This is the claim ok. So, again fix ϵ greater than 0 and choose N so large, that if small n is greater than N , then $\|W_n - V\|$ is less than ϵ and $\|W_n - V_n\|$ is less than ϵ ok.

(Refer Slide Time: 19:46)

$$\|v_n - v\| \leq \|v_n - w_n\| + \|w_n - v\| < 2\epsilon.$$

This completes the proof.

Ex: show that \overline{V} is complete.

Theorem: Let V be a normed V.S. and let W be a Banach space. Define the completion of V by \overline{V} . Then any bounded linear map $L: V \rightarrow W$ can be extended to a bounded linear map from \overline{V} to W .

Then it is immediate, it is immediate that $\|W_n - V\|$ would be less than or equal to $\|V_n - W_n\| + \|W_n - V\|$ will be less than 2ϵ ok. So, this shows, this completes the proof ok.

So, what we have shown is the following; we have shown that if you start if you start with a vector space V and you have a dense subset W dense subspace W , such that W close such that every Cauchy sequence in W has a limit in V , then V itself is complete.

Now, final exercise for you show that this \bar{V} is complete. And that will conclude the sketch of the proof that you can always complete a normed vector space. You can put it inside a larger sub larger normed vector space which is complete.

Not only that, once you solve this exercise, you will realize that this F of V is actually dense is actually dense in V . So, that essentially shows that you can embed any normed vector space as the dense as a dense subspace of a complete normed vector space.

Now, I am going to finish this video by one more theorem that is very useful in applications ok. So, what it says is the following; this is essentially about extension of linear maps to the completion. Let V be a normed vector space normed vector space and let W be a Banach space be a Banach space ok.

Denote the completion of V by \bar{V} ok, then any bounded linear map L from V to W can be extended to a linear map from a bounded linear map of course, can be extended to a bounded linear map from \bar{V} to W ok. If you start with the linear map from V to W it extends to the completion.

(Refer Slide Time: 22:53)

$F: V \rightarrow V$

Proof: $F(V)$ is a subspace of \overline{V} ,
we identify V and $F(V)$ and
(consider)

$L: F(V) \rightarrow W$ Bounded linear

$\tilde{L}: \overline{V} \rightarrow W$. Bounded linear extension.

\tilde{L} exists because $\overline{F(V)} = \overline{V}$
and L is uniformly continuous.

Suppose $x, y \in \overline{V}$ and $x_n \rightarrow x$ and $y_n \rightarrow y$
 $x_n, y_n \in F(V)$.

So, first of all before we even begin the proof, we have to understand what does, it mean that L extends. Well, since F of V is a subspace of W , we just identify we identify V and F of V , because anyway, so I must recall F is the map from V to \overline{V} that we studied before.

So, since F of V is a subspace of not W is a subspace of \overline{V} , we identify V and F of V and consider L to be defined from F of V to W ok, bounded linear. So, there is a bit of unwinding to do and it is better that you do it by yourself, rather than me explaining what is happening there is nothing deep going on, but it might seem a bit confusing. Because we are starting off with the map L from V to W , now I am just saying that identify this isometric embedding of V inside \overline{V} F of V with V and treat L as a map from F of V to W ok.

So, what the claim is that, if you start with this map L from F of V to W you can get a map \tilde{L} from \overline{V} to W that is the claim bounded linear extension it is a bounded linear

extension ok. Now, how are we going to show this? Well this, L tilde exists, L tilde exists because of the previous exercise you already know that F of V closure is going to be V bar that is one, and L is uniformly continuous.

All bounded linear maps are uniformly continuous that we established previously when we studied the continuity of linear mappings between normed vector spaces. Because L is uniformly continuous and the fact that F of V closure is nothing but V bar, note here it is the closure ok and here it is just a notation. Since F of V closure is nothing but V bar, and L is uniformly continuous and uniformly continuous mappings extend continuously to the closure ok.

So, we have this map we have this map, L bar from a V bar to W . Note, this is the place where we use the fact that W is a Banach space. So, we get a continuous linear extension L tilde from V bar to W . The only thing that remains to be shown is that this L tilde is actually linear and that is rather straightforward.

So, suppose x comma y are elements of V bar ok, and x_n converges to x and y_n converges to y , where x_n and y_n are coming from they are coming from V ok, which I am identifying with F of V tacitly ok. So, take two points x comma y in the completion V bar and consider sequences x_n converging to x and y_n converging to y , where x_n and y_n are coming from V which let me just for clarity sake just identify it already with F of V ok.

(Refer Slide Time: 26:35)

$x_n + y_n \rightarrow x + y$ Obviously.

We also have $L(x_n + y_n) \rightarrow \tilde{L}(x + y)$.
" $L(x_n) + L(y_n)$ obviously.

$L(x_n) \rightarrow \tilde{L}(x)$, $L(y_n) \rightarrow \tilde{L}(y)$.

$$\tilde{L}(x + y) = \tilde{L}(x) + \tilde{L}(y)$$
$$\tilde{L}(cx) = c \tilde{L}(x).$$

Then, $x_n + y_n$ converges to $x + y$, this is obvious; obviously ok. Now, what we have to do is to show that L of $x_n + y_n$ converges to L tilde of $x + y$ ok. This is also obvious sub we also have we also have L of $x_n + y_n$ converges to L tilde of $x + y$; obviously, this also this follows from the very fact that L tilde is an extension and it is a continuous extension and since $x_n + y_n$ converges to $x + y$, L of $x_n + y_n$ must converge to L tilde of $x + y$ ok.

Now, similarly we have L of x_n converges to L tilde of x and L of y_n converges to L tilde of y . This is again by the fact that L tilde is a continuous linear extension. Putting all this together we get that L tilde of $x + y$ is equal to L tilde of x plus L tilde of y this is because L is linear. So, this part L of $x_n + y_n$ is just L of x_n plus L of y_n ok.

So, this concludes the fact that L tilde of x plus y is L tilde of x plus L tilde of y . So, we have essentially exploited the linearity of the map L on the space F of V and somehow translated to L tilde by passing to limits. Similarly, you can show that L tilde of Cx is C L tilde of x exactly in the same way.

This will prove that this extension L tilde is linear. It is already continuous from the fact that we got L tilde by using a continuous extension theorem that we saw in a previous video. So, this was a somewhat longer module, but work on it. It is not that difficult it consists of a number of trivial checks that I have left for you intentionally, so that you will have a deeper understanding of what is happening.

So, the moral of the story is, you have for a given normed vector space. You all always have a completion and all linear maps to Banach spaces from the normed vector space extend to be bounded linear maps in the completion also.

This is a course on Real Analysis and you have just watched the video on the Completion of a Normed Vector Space.
