Upper and Lower Limits

(Refer Slide Time: 00:22)

Upper and lower limits.

Definition: Let $x_n \in \mathbb{R}$ be a sequence.
 Define $S \subseteq \mathbb{R} \cup \{-\infty, \infty\}$
 to be
 $S := \{x \in \mathbb{R} \cup \{-\infty, \infty\} : \exists \text{ subsequence } x_{n_k} \rightarrow x\}.$
 $\limsup_{n \rightarrow \infty} x_n := \sup S.$
 $\liminf_{n \rightarrow \infty} x_n := \inf S.$

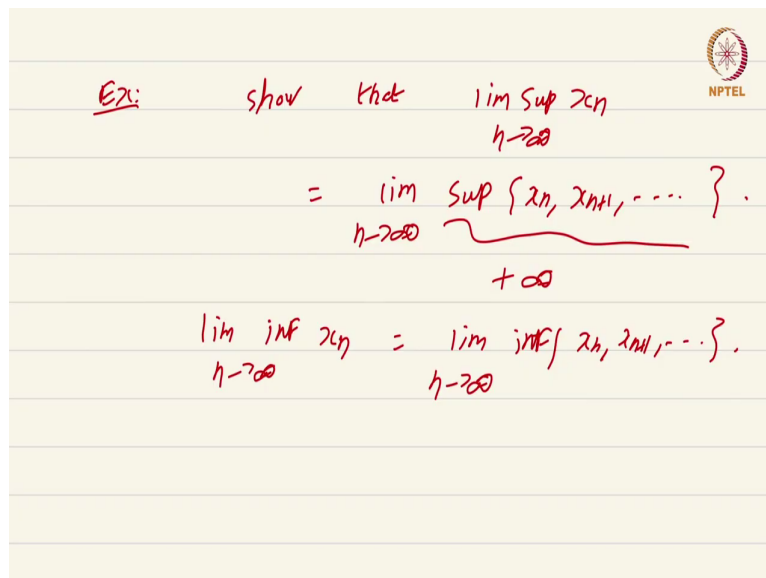

In this video we are going to study Upper and Lower limits which are more popularly known as \limsup and \liminf . They are very useful in the study of sequences that are actually not convergent. So, the definition is quite straightforward, definition let x_n in \mathbb{R} be a sequence define defined S which is actually a subset of \mathbb{R} union minus infinity infinity the extended real numbers with the points minus infinity and infinity added.

I remind you again that these are not real points they are just a notation, to be set of all x in \mathbb{R} union minus infinity infinity such that there is subsequence x_{n_k} that converges to x or rather

I mean it could converge to x if it is a real number or it diverges. If you want the point infinity to bear in be in this set S , there should be a subsequence that diverges to plus infinity. Similarly, if you want minus infinity to be there in this set you need a sequence x_n subsequence x_{n_k} that diverges to minus infinity.

Now, the \limsup of x_n ; n going to infinity is just by definition supremum of the set S , if this set S is unbounded or if this set S contains the point plus infinity the supremum is taken to be plus infinity. Similarly, $\liminf x_n$; n going to infinity is just the infimum of the set S with the same remarks, if the set S is either not bounded below or it contains the point minus infinity then the \liminf is just minus infinity.

(Refer Slide Time: 02:37)

Ex: show that $\limsup_{n \rightarrow \infty} x_n$

$$= \lim_{n \rightarrow \infty} \sup \{x_n, x_{n+1}, \dots\}.$$

$+\infty$

$$\liminf_{n \rightarrow \infty} x_n = \lim_{n \rightarrow \infty} \inf \{x_n, x_{n+1}, \dots\}.$$

So, immediately you can characterize this \limsup and \liminf in several ways, I am going to leave one exercise for you. Show that $\limsup_{n \rightarrow \infty} x_n$ is just equal to $\lim_{n \rightarrow \infty} x_n$.

going to infinity supremum or rather limit $n \rightarrow \infty$ yeah this is correct, limit $n \rightarrow \infty$ supremum of x_n, x_{n+1}, \dots . You just start taking the supremum's of the tails and then take limit $n \rightarrow \infty$.

So, there is one just this one remark that needs to be made, this could be plus infinity ok. So, you will have to be a bit careful when you analyze and prove this exercise, you will be taking limits where some of the terms could be infinity. So, I want you to handle this with a bit of delicateness it is not that difficult, but let me just tell you that this could be plus infinity. And not only that if it is going to be plus infinity for some n it is going to be plus infinity throughout, that will give you the key.

So, it is just going to be a constant plus infinity, it cannot happen that supremum x_n, x_{n+1}, \dots is plus infinity, but when you remove finitely many terms suddenly the supremum becomes finite that is not going to happen ok. Similarly, $\liminf_{n \rightarrow \infty} x_n$ is just limit $n \rightarrow \infty$ of infimum of x_n, x_{n+1}, \dots and so on ok.

So, these are the basic properties of, I mean this is one of the basic properties of \liminf and \limsup , you can characterize it in terms of both sub sequential limits as well as this definition. Now, about characteristic properties there is a very good characteristic property of \limsup and \liminf that you must know, that you must know and this formulation is what is used in proofs most often.

(Refer Slide Time: 04:48)

Theorem: Let x_n be a seq.
then $S^* = \limsup_{n \rightarrow \infty} x_n$ has the following
two properties

(i). $\exists x_{n_k}$ s.t. $x_{n_k} \rightarrow S^*$
(ii). If $x > S^*$, $\exists N$ s.t. if
 $n > N$, then $x_n < x$.

Proof: Suppose $S^* = +\infty$. Then x_n is
unbounded. Easy to find $x_{n_k} \rightarrow \infty$.

Theorem: let x_n be a sequence; let x_n be a sequence then $\limsup_{n \rightarrow \infty} x_n$ has the following 2 properties. Property number 1, there exist a subsequence x_{n_k} such that $x_{n_k} \rightarrow S^*$ if you do not mind let me just call this $\limsup x_n = S^*$ this is a common notation $x_{n_k} \rightarrow S^*$ ok.

Property number 2 if $x > S^*$, if you choose a real number that is greater than S^* there exist N , such that if $n > N$ then $x_n < x$ ok.

So, in some sense the \limsup is not an upper bound for the sequence it is an essential upper bound, after a particular point you cannot become greater than, I mean you cannot become greater than any number greater than the \limsup ok that is a mouthful. But it is a very very

intuitive property. The sequence will not be too far greater than \limsup provided you go far enough in the sequence.

So, let us prove this characterization. Proof: suppose S^* is $+\infty$ ok. Then the only thing the only way by which this can happen is then x_n is unbounded, it is an unbounded sequence, it is easy to find x_{n_k} diverging to $+\infty$ and I am going to leave it to you ok.

(Refer Slide Time: 07:15)

Suppose x_n is bounded. Then clearly S^* is a real number. This means there must be at least one conv. subsequence. This set S is a non-empty set of real numbers. we can always find a sequence in S that conv. to $\sup S$. Now for each $\epsilon > 0$, x_n in y_n , \exists some subsequence that conv. to y_n . It is easy to construct a subsequence of x_n that conv. to $\sup S$.

Now suppose x_n is bounded x_n is a bounded sequence then clearly S^* is a real number obviously ok. Now, this means there must be at least; there must be at least 1 convergent subsequence this is just the Bolzano Weierstrass theorem convergence subsequence, any bounded sequence must have a convergence subsequence ok.

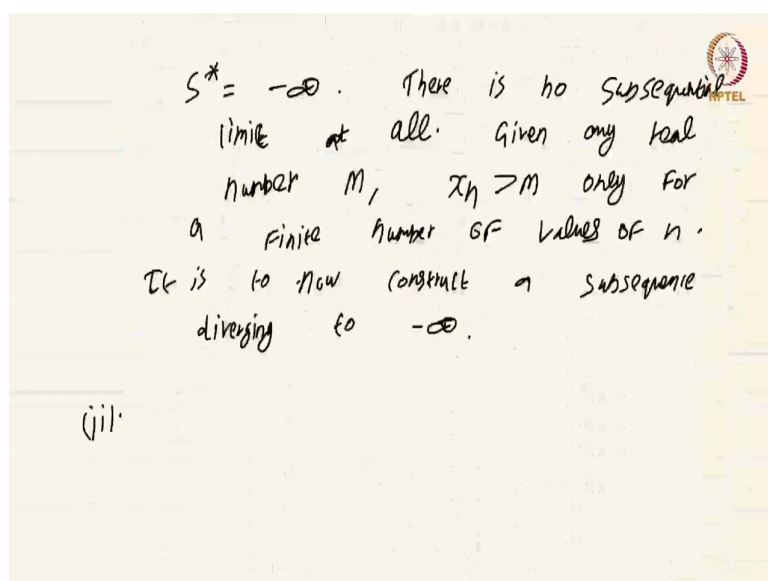

So, this set S is non empty; is a non empty set of real numbers; set of real numbers ok and we already know that given any non empty set of real numbers we can always find, we can always find a point a sequence.

Let us say not just a point we can always find, we can always find a sequence; we can always find a sequence in S that converges to supremum of S oh. I must mention this S , set S is the same that we saw in the definition of \limsup I have defined a set S I am going to reuse the notation ok.

Now, what I am trying to say is that given this set S is a nonempty and bounded set, we can always find a sequence in S that converges to supremum of S , this is always true. Now, for each point in the sequence, so let us just call this sequence y_n ok. Let us just call this sequence y_n , for each point in y_n there is some subsequence that converges of x_n that converges to y_n ok. Now, it is easy it is easy the very similar arguments we have done several times before it is easy to construct a subsequence of x_n x_{n_k} of x_n that converges to supremum of S .

This is something that we have done several times earlier, some very similar arguments. So, I am going to leave the rest to you ok. So, there is a third possibility that we should consider.

(Refer Slide Time: 10:44)

What if this set of subsequential limits that is a empty set ok not an empty set, it consist of only minus infinity that is possible, suppose S^* is minus infinity what if the \limsup itself is minus infinity ok.

This just means there is no subsequential limit; there is no subsequential limit whatsoever limit at all ok. That just means for given any real number, given any real number m given any real number m x_n is greater than m only for a finite number of values number of values of n . Why is this the case? Well think about it this way, if it is not true that x_n is greater than m only for a finitely many values of n then that just means that there is a subsequence of x_n that is strictly greater than n .

Now, there are two possibilities, this subsequence could be bounded in which case we can apply the Bolzano Weierstrass theorem to get a further subsequence that converges

contradicting the fact that there is no subsequential limit at all. On the other hand if this x_n is unbounded then you would get a subsequence that diverges to plus infinity, again contradicting the fact that there is no subsequential limit whatsoever ok.

So, what this shows is that only finitely many values of n are for only finitely many values of n x_n is greater than M , it is easy to now construct, it is easy to now construct a subsequence diverging to minus infinity; diverging to minus infinity ok. So, this will provide for you the subsequence that diverges to minus infinity.

Now, for on to part the second part, let us just recall the second part asks us to show that if a number is greater than S^* , then there exist n such that if n is greater than n then x_n is less than x ok. Now, again we can use a similar logic to what we have seen so far to the following.

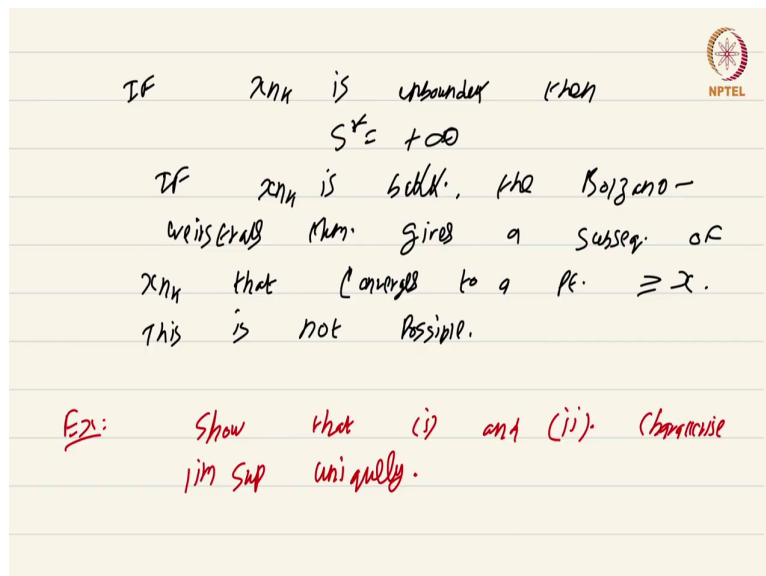

(Refer Slide Time: 13:44)

limit at all. Given any real number M , $x_n > M$ only for a finite number of values of n . It is to now construct a subsequence diverging to $-\infty$.

(ii). Suppose S^* is a real number. and $x > S^*$. If $x_n > x$ for infinitely many n , then there is a subseq. $x_{n_k} > x \forall k$.

Suppose this S^* is a real number, it is a real number, of course if S^* is plus infinity there is really nothing to show ok. So, suppose S^* is a real number and x is greater than S^* ok, then if x_n is greater than x for infinitely many values infinitely many n then there is a subsequence, again same logic there is a subsequence x_{n_k} which is strictly greater than x for all k right.

(Refer Slide Time: 14:39)

IF x_n is unbounded then $S^* = +\infty$

IF x_n is bdd., the Bolzano-Weierstrass Thm. gives a subseq. of x_n that converges to a pt. $\geq x$. This is not possible.

Ex: Show that (i) and (ii) characterize \limsup uniquely.

Now, there are two possibilities, if x_{n_k} is unbounded, then in fact S^* is plus infinity which is nonsense. On the other hand if x_{n_k} is bounded, the Bolzano Weierstrass theorem; the Bolzano Weierstrass theorem Weierstrass theorem guarantees or let me just say gives a subsequence of x_{n_k} that converges to a point greater than or equal to x , which is again this is not possible. Because x is the supremum of all subsequential limits ok.

Now, the case where x is just, S^* is just minus infinity is very easy, if S^* is minus infinity it is rather trivial to show this ok. Now, this concludes actually concludes the proof of property 1 and 2 I just want to make a remark or rather I will give an exercise show that 1 and 2 characterize \limsup uniquely. That means, if there is a number that satisfies 1 and 2 then that has got to be the \limsup ok.

So, I am going to leave further exercises in the lecture notes where you extend the root test and the ratio test, make it slightly stronger incorporating our knowledge of \limsup and \liminf . And I am also going to leave the Cartan Hadamard theorem for the radius of convergence of a power series which is just a straightforward application of the root test to you. You will be able to find out compute a formula for the radius of convergence of a power series.

There are some more examples also of these notions in the lecture notes. This is a course on real analysis and you have just watched the video on upper and lower limits.
