EXTENSION THEOREMS

Method of Reflection.

Notation.  $x \in \mathbb{R}^N$   $x = (x_1, \dots, x_{N-1}, x_N) = (x', x_N)$   
 $x' = (x_1, \dots, x_{N-1}) \in \mathbb{R}^{N-1}$   
 $\mathbb{R}_+^N = \{x \in \mathbb{R}^N \mid x_N > 0\}$

$x' = (x_1, \dots, x_{N-1}) \in \mathbb{R}^{N-1}$   
 $\mathbb{R}_+^N = \{x \in \mathbb{R}^N \mid x_N > 0\}$

Thm. Let  $1 \leq p < \infty$ . Let  $u \in W^{1,p}(\mathbb{R}_+^N)$ . Define  $u^*$  on  $\mathbb{R}^N$  by

$$u^*(x) = \begin{cases} u(x', x_N) & x_N > 0 \\ u(x', -x_N) & x_N < 0 \end{cases}$$

Then  $u^* \in W^{1,p}(\mathbb{R}^N)$  and  $\|u^*\|_{W^{1,p}(\mathbb{R}^N)} = 2 \|u\|_{W^{1,p}(\mathbb{R}_+^N)}$   
 $\|u^*\|_{W^{1,p}(\mathbb{R}^N)} = 2 \|u\|_{W^{1,p}(\mathbb{R}_+^N)}$   
 In particular  $u \mapsto u^*$  defines an extension operator from  $W^{1,p}(\mathbb{R}_+^N)$  into  $W^{1,p}(\mathbb{R}^N)$ .

We will now look at Extension Theorems so, we already saw that if you, if  $\Omega$  admitted, a extension operators for  $W^{1,p}(\Omega)$  then we can improve Friedrich's theorem by having the conversions of the derivatives in  $L^p(\Omega)$  rather than only on relatively compact sets. And also as I already remarked earlier, if you have many results using calculus can we prove in  $\mathbb{R}^N$  because you are not constrict, constrained by any boundary and therefore, and you have tools like convolution and so on.

And then it is easier to restrict it, so having a prolongation operator is a good thing, for instance if you are having a function on  $[0, 1]$  for instance so, any  $W^{1,p}(\Omega)$  function is going to be an absolutely continuous function as we saw. That means these values at the end points are well defined.

And now, you will simply connect it by means of a straight line and you can prove so, if you write down the formulae for these things. So, this is  $u$  so this will be  $u$  of 0 and this will be  $u$  of 1 and then you can easily write out what is this new function in  $\mathbb{R}$ . And you can show that it is, in fact, an extension operator.

But, you can, there are many of them you can also do say, another one like this, this will also be an extension operator. So, you can write down the formulae, you can check it for yourself, and will probably see it in exercises on the assignments. Now, we are going to describe the method of reflection, which gives you a very general method for when, especially when the flat portions of the boundary give you an extension.

**Method of reflection:** so first some notation.

*Notations:* so, we take  $x \in \mathbb{R}^N$ ,  $x = (x_1, \dots, x_{N-1}, x_N)$ ,  $x' = (x_1, \dots, x_{N-1})$ ,

$x_N = (x_1, \dots, x_{N-1}) \in \mathbb{R}^{N-1}$ ,  $\mathbb{R}_+^N = \{x \in \mathbb{R}^N : x_N > 0\}$ .

So, now we have the following theorem.

**Theorem:** Let  $1 \leq p < \infty$ ,  $u \in W^{1,p}(\mathbb{R}_+^N)$ . Define  $u^*$  on  $\mathbb{R}^N$  by

$$\begin{aligned} u^*(x) &= u(x', x_N), \text{ if } x_N > 0, \\ &= u(x', -x_N), \text{ if } x_N < 0. \end{aligned}$$

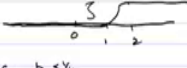

Then  $u^* \in W^{1,p}(\mathbb{R}^N)$  and  $|u^*|^p_{0,p,\mathbb{R}^N} = 2 |u|^p_{0,p,\mathbb{R}_+^N}$ ,  $|u^*|^p_{1,p,\mathbb{R}^N} = 2 |u|^p_{1,p,\mathbb{R}_+^N}$ . In particular  $u \rightarrow u^*$  defines an extension operator from  $W^{1,p}(\mathbb{R}_+^N)$  into  $W^{1,p}(\mathbb{R}^N)$ .

(Refer Slide Time: 06:17)

Pf: Clearly  $u^* \in L^p(\mathbb{R}^N)$  and  $|u^*|_{0,p,\mathbb{R}^N}^p = 2|u|_{0,p,\mathbb{R}_+^N}^p$   
 We need to study the derivatives of  $u^*$ .

Step 1: let  $\zeta \in C^\infty(\mathbb{R})$  s.t.  $0 \leq \zeta \leq 1$ ,  $\zeta(t) = \begin{cases} 0 & t \leq 1 \\ \zeta(t-2) & t \geq 2 \end{cases}$

$\zeta_k(t) = \zeta(k t)$ . note that  $\zeta_k(t) = \begin{cases} 0 & t \leq \frac{1}{k} \\ \zeta(k t - 2) & t \geq \frac{2}{k} \end{cases}$

Step 1: let  $\zeta \in C^\infty(\mathbb{R})$  s.t.  $0 \leq \zeta \leq 1$ ,  $\zeta(t) = \begin{cases} 0 & t \leq 1 \\ \zeta(t-2) & t \geq 2 \end{cases}$

$\zeta_k(t) = \zeta(k t)$ . note that  $\zeta_k(t) = \begin{cases} 0 & t \leq \frac{1}{k} \\ \zeta(k t - 2) & t \geq \frac{2}{k} \end{cases}$

Step 2: let  $\varphi \in C_c^\infty(\mathbb{R}^N)$  let  $1 \leq i \leq N-1$ .

$$\int_{\mathbb{R}_+^N} u^* \frac{\partial \varphi}{\partial x_i} dx = \int_{\mathbb{R}_+^N} u \frac{\partial \varphi}{\partial x_i} dx$$

where  $\varphi(x'_i, x_N) = \varphi(x'_i, x_N) + \varphi(x'_i, -x_N)$ ,  $x_N > 0$ .

*proof:* clearly  $u^* \in L^p(\mathbb{R}^N)$  and  $|u^*|_{0,p,\mathbb{R}^N}^p = 2|u|_{0,p,\mathbb{R}_+^N}^p$ .

There is nothing to see here, it is just an integral that is repeated twice, once in the upper half plane once in the lower half plane by change of variable  $x_N$  going to minus  $x_N$ , you can convert it to that integral so you get twice.

So, we need to study the derivatives of  $u^*$ .

**first step :** we take  $\zeta \in C^\infty(\mathbb{R})$ ,  $0 \leq \zeta \leq 1$ ,  $\zeta(t) = 0$ , if  $t \leq 1$

$= 1$ , if  $t \geq 2$ .

And you define  $\zeta_k(t) = \zeta(kt)$ , so that  $\zeta_k(t) = 0$ , if  $t \leq \frac{1}{k}$

$$= 1, \text{ if } t \geq \frac{2}{k}.$$

**step 2** : let  $\phi \in D(\mathbb{R}^N)$ ,  $1 \leq i \leq N - 1$

$$\int_{\mathbb{R}^N} u^* \frac{\partial \phi}{\partial x_i} dx = \int_{\mathbb{R}_+^N} u \frac{\partial \psi}{\partial x_i} dx.$$

where  $\psi(x', x_N) = \phi(x', x_N) + \phi(x', -x_N)$ , for  $x_N > 0$ .

(Refer Slide Time: 09:56)

$$\begin{aligned} & \int_{\mathbb{R}_+^N} u \frac{\partial \psi}{\partial x_i} + \int_{\mathbb{R}_+^N} u(x', -x_N) \frac{\partial \psi}{\partial x_i}(x', x_N) \\ & + b \omega(\mathbb{R}_+^N) \quad \text{we multiply it by } \zeta_n(x_N), \quad \zeta_n \psi \in \omega(\mathbb{R}_+^N) \\ & \int_{\mathbb{R}_+^N} u \frac{\partial (\zeta_n \psi)}{\partial x_i} dx = - \int_{\mathbb{R}_+^N} \frac{\partial \zeta_n}{\partial x_i} \zeta_n(x_N) \psi(x) dx \\ & 1 \leq i \leq N-1 \Rightarrow \\ & \int_{\mathbb{R}_+^N} u \frac{\partial (\zeta_n \psi)}{\partial x_i} dx = \int_{\mathbb{R}_+^N} u(x_N) \zeta_n(x_N) \frac{\partial \psi(x)}{\partial x_i} dx \\ & \zeta_n(b) \rightarrow 1 \text{ as } n \rightarrow \infty, \text{ if } b > 0. \\ & \text{DCT} \quad \int_{\mathbb{R}_+^N} u(x_N) \frac{\partial \psi}{\partial x_i}(x) dx = - \int_{\mathbb{R}_+^N} \frac{\partial \zeta_n}{\partial x_i}(x_N) \psi(x) dx \end{aligned}$$

$$\begin{aligned} & \int_{\mathbb{R}_+^N} u \frac{\partial (\zeta_n \psi)}{\partial x_i} dx = \int_{\mathbb{R}_+^N} u(x_N) \zeta_n(x_N) \frac{\partial \psi(x)}{\partial x_i} dx \\ & \zeta_n(b) \rightarrow 1 \text{ as } n \rightarrow \infty, \text{ if } b > 0. \\ & \text{DCT} \quad \int_{\mathbb{R}_+^N} u(x_N) \frac{\partial \psi}{\partial x_i}(x) dx = - \int_{\mathbb{R}_+^N} \frac{\partial \zeta_n}{\partial x_i}(x_N) \psi(x) dx \\ & \Rightarrow (1 \leq i \leq N-1) \quad \int_{\mathbb{R}_+^N} u^* \frac{\partial \phi}{\partial x_i} dx = - \int_{\mathbb{R}_+^N} \frac{\partial u^*}{\partial x_i} \phi(x', x_N) - \int_{\mathbb{R}_+^N} \frac{\partial u}{\partial x_i} \phi(x', -x_N) dx. \end{aligned}$$

Integral of  $u$  over  $\mathbb{R}^n$  plus  $d\Phi$  by  $dx_i$  plus integral over  $\mathbb{R}^n$  minus of  $u$  of  $x$  dash minus  $x_n$ ,  $d\Phi$  by  $dx_i$   $x$  dash minus,  $x$  dash  $x_n$  sorry and now if you make a change of variable. Take minus  $x$  equals  $y$  so that  $y$  will become in  $\mathbb{R}^n$  plus and then  $u$  this will become minus  $y$  and that is why you have this second term here in the thing so, this is just a change of variable, simple change of variable which we are doing.

So, now unfortunately  $\Psi$  does not belong to  $d$  of  $\mathbb{R}^n$  plus so, we because we do not have, we are just taking a  $\Phi$  could be a function whose support is something like this and therefore it need not vanish here and I am just taking the reflection. This  $\Phi$  of  $x$  dash minus  $x_n$ , this reflection of this path over here and therefore it need not vanished anywhere near the boundary. So, therefore we are going to multiply it by  $\zeta_k$  so, we multiply  $\Psi$  by  $\zeta_k$   $x_n$ . Then we have the  $\zeta_k \Psi$  belongs to  $d$  of  $\mathbb{R}^n$  plus because  $\zeta_k$  will be 0, look at  $\zeta_k$ ,  $\zeta_k$  will be 0, if  $x_n$  will be 0 if  $1$  over  $k$ .

So, this small layer here, where it will be 0 and therefore when you multiply it by  $\zeta_k$ ,  $\Phi$  of  $\zeta_k$ , a  $\Psi$  times  $\zeta_k$  belongs to  $d$  of  $\mathbb{R}^n$  plus. Therefore, you have by the definition of the distribution of derivative,  $d$  of integral over  $\mathbb{R}^n$  plus  $u$   $d$  by  $dx_i$ ,  $\zeta_k \Psi$   $dx$  is equal to minus integral over  $\mathbb{R}^n$  plus  $du$  by  $dx_i$  of  $x$   $\zeta_k$  which depends only on  $x_n$  and you have  $\Psi$  of  $x$   $dx$ . So, now let us now  $1$  is less than equal to  $i$  is less than equal to  $n$  minus  $1$  and that implies that integral over  $\mathbb{R}^n$  plus of  $u$   $d\zeta_k \Psi$  by  $dx_i$   $dx$  is equal to integral over  $\mathbb{R}^n$  plus  $u$  of  $x$  and then  $\zeta_k$  of  $x_n$  because that is like a constant, it will not  $(())(13:07)$  to  $d\Psi$  by  $dx_i$  at  $x$ .

So, now let us what happens, we have that  $\zeta_k$  of  $x$  goes to  $1$  point wise because  $\zeta_k$  of  $x$  will be  $1$  if  $x$  is,  $x_n$  is bigger than  $2$  by  $k$  so, ultimately as  $k$  tends to infinity is almost all of  $\mathbb{R}^n$  plus will slowly get covered and therefore point wise this converges to a  $1$ . And for all point wise, for all  $t$  greater equal to  $0$ , due to  $k$  of  $t$  let us say.

So, we can now apply the dominated conversions to other meanings. each of these integrals you have two fixed functions and  $\zeta_k$  which converges to  $1$ . And the modulus is bounded by  $\text{Mod } \Psi$  into  $du$  by  $dx_i$  and here or  $d\Psi$  by  $dx_i$  and  $u$  and they are integrable functions therefore, you have no problems at all.

So, by the dominated convergence theorem, you can pass to the limit so, the left-hand side when you go to, we will give you integral over  $\mathbb{R}^n$  plus of  $u$   $x$   $d\Psi$  by  $dx_i$  at  $x$   $dx$  equal to

minus integral over  $\mathbb{R}^n$  plus  $du \, dy \, dx$  at  $x = \Psi(x)$ . So, now going back to the definition of  $\Psi$  so, what is the definition of  $\Psi$ ?

$\Psi$  if this function you go back and then you write this back as an integral over  $\mathbb{R}^n$  instead of  $\mathbb{R}^n$  plus and use again the fact the 1 is less than equal to  $i$  is less than equal to  $n - 1$  and therefore this gives you that integral over  $\mathbb{R}^n$  of  $u^*$ ,  $d\Phi$  by  $dx$  equal to minus integral over  $\mathbb{R}^n$   $du$  by  $dx$   $\Phi(x)$ ,  $\Phi(x)$ ,  $du$  by  $dx$   $\Phi$ . So, I am going to like the  $x$  dash  $x_n$  minus so, this is integral  $\mathbb{R}^n$  plus minus integral  $\mathbb{R}^n$  plus  $du$  by  $dx$ .  $\Phi(x)$  dash minus  $x_n \, dx$ .

(Refer Slide Time: 16:11)

$$\text{Define } \left( \frac{\partial u}{\partial x_i} \right)^* (x', x_n) = \begin{cases} \frac{\partial u}{\partial x_i} (x', x_n) & x_n > 0 \\ \frac{\partial u}{\partial x_i} (x', -x_n) & x_n < 0. \end{cases}$$

$$(\dagger) \Rightarrow \int_{\mathbb{R}^n} u^* \frac{\partial \varphi}{\partial x_i} dx = - \int_{\mathbb{R}^n} \left( \frac{\partial u}{\partial x_i} \right)^* \varphi.$$

$$\Rightarrow 1 \leq i \leq n-1, \quad \frac{\partial u^*}{\partial x_i} = \left( \frac{\partial u}{\partial x_i} \right)^* \in L^p(\mathbb{R}^n)$$

$$\left| \frac{\partial u^*}{\partial x_i} \right|_{0, \mathbb{R}^n} = 2 \left| \frac{\partial u}{\partial x_i} \right|_{0, \mathbb{R}_+^n}.$$

Step 3  $i = n$ .  $\varphi \in \mathcal{D}(\mathbb{R}^n)$ .

$$\int_{\mathbb{R}^n} u^* \frac{\partial \varphi}{\partial x_n} dx = \int_{\mathbb{R}_+^n} u \frac{\partial \varphi}{\partial x_n} dx$$

$$\Rightarrow 1 \leq i \leq n-1, \quad \frac{\partial u^*}{\partial x_i} = \left( \frac{\partial u}{\partial x_i} \right)^* \in L^p(\mathbb{R}^n)$$

$$\left| \frac{\partial u^*}{\partial x_i} \right|_{0, \mathbb{R}^n} = 2 \left| \frac{\partial u}{\partial x_i} \right|_{0, \mathbb{R}_+^n}.$$

Step 3  $i = n$ .  $\varphi \in \mathcal{D}(\mathbb{R}^n)$ .

$$\int_{\mathbb{R}^n} u^* \frac{\partial \varphi}{\partial x_n} dx = \int_{\mathbb{R}_+^n} u \frac{\partial \varphi}{\partial x_n} dx$$

where  $\varphi(x', x_n) = \varphi(x', x_n) - \varphi(x', -x_n) \quad x_n > 0.$

And therefore, you now define,  $du$  by  $dx_i$  star is the same function of reflection so,  $x$  dash  $x_n$  equal to  $du$  by  $dx_i$ ,  $x$  dash  $x_n$  if  $x_n$  is positive and  $du$  by  $dx_i$ ,  $x$  dash minus  $x_n$  if  $x_n$  is

negative. Then star implies that the integral over  $R_n$   $du, u^* d\Phi$  by  $dx_i dx$  is equal to minus integral  $du$  by  $dx_i^* \Phi$  over  $R_n$ .

So, this implies let for  $1 \leq i \leq n-1$  we have  $du^*$  by  $dx_i \Phi$  is nothing but,  $du$  by  $dx_i^*$  and therefore this belongs to  $L_p$  of  $R_n$  and in fact if you take the  $L_p$  Norm of this, you will precisely get 2 times the so,  $du$  by,  $du^*$  by  $dx_i$   $0 \leq p < \infty$  will be in fact twice integral, twice  $du$  by  $dx_i$  over  $R_n$  plus. So, this is proved.

So, now we have to consider step 3 where we are taking  $i = n$ , the derivative in the  $n$ th direction. So, once again you take  $\Phi$  and  $d$  of  $R_n$  and now you take integral over  $R_n$ , of  $u^* d\Phi$  by  $dx_n dx$  and then if you expand it, the definition of  $u^*$  again  $E_n$  plus  $E_n$  minus, you break the integral and on  $R_n$  minus you make a change of variable.

But now since we have a derivative in the  $n$ th direction, when you differentiate with respect to  $x_n$ , you pick up a minus sign. And therefore, this will give you the integral over  $R_n$  plus of  $u d\Phi$  by  $dx_n dx$ . Where,  $\Phi$  of  $x - x_n$  is equal to  $\Phi$  of  $x - x_n$  minus  $\Phi$  of  $x - x_n$  minus  $x_n$ . This is for  $x_n$  positive.

(Refer Slide Time: 19:27)

$$\int_{\mathbb{R}_+^N} u \frac{\partial (\zeta_n(x) \psi(x))}{\partial x_n} dx = - \int_{\mathbb{R}_+^N} \zeta_n(x) \psi(x) dx$$

$$\frac{\partial (\zeta_n(x) \psi(x))}{\partial x_n} = \zeta_n(x) \frac{\partial \psi}{\partial x_n} + \psi(x) \zeta_n'(x)$$

$$\int_{\mathbb{R}_+^N} \zeta_n(x) \psi(x) \zeta_n'(x) dx$$

$\psi(x,0) = 0 \Rightarrow$  MVT  $|\psi(x, x_n)| \leq C|x_n| < \infty$

dep. on the bound for derivatives of  $\psi$

$\zeta'$  is bad fn. which is non-zero only when  $1 \leq 2$

$$\frac{\partial (\zeta_n(x) \psi(x))}{\partial x_n} = \zeta_n(x) \frac{\partial \psi}{\partial x_n} + \psi(x) \zeta_n'(x)$$

$$\int_{\mathbb{R}_+^N} \zeta_n(x) \psi(x) \zeta_n'(x) dx$$

$\psi(x,0) = 0 \Rightarrow$  MVT  $|\psi(x, x_n)| \leq C|x_n| < \infty$

dep. on the bound for derivatives of  $\psi$

$\zeta'$  is bad fn. which is non-zero only when  $1 \leq 2$

$$\left| \int_{\mathbb{R}_+^N} \zeta_n(x) \psi(x) \zeta_n'(x) dx \right| = k \left| \int_{\mathbb{R}_+^N} \zeta_n(x) \psi(x) \zeta_n'(x) dx \right|$$

So, again this is not a,  $d \mathbb{R}^n$  plus function and therefore,  $d \Psi$ . Again we multiply it by  $\zeta_k$  and therefore you have integral over  $\mathbb{R}^n$  plus  $u$  of  $d \zeta_k x^n \Psi(x)$  by  $dx^n$  equal to minus integral  $du$  by  $dx^n$ , over  $\mathbb{R}^n$  plus of  $\zeta_k x^n, \Psi$  of  $x$   $dx$ .

So, now you look at the left hand side again so,  $d$  by  $dx^n$  of  $\zeta_k x^n, \Psi$  of  $x$  so, in the previous thing we were taking the derivatives up to  $n-1$  so, this function was like a constant but, now you have to differentiate with respect to that also.

So, this will give you  $\zeta_k x^n, d \Psi$  by  $dx^n$  plus  $k$  times  $\Psi$  of  $x$  into  $\zeta_k$  dash  $k x^n$ . Because, we have defined  $\zeta_k$  as  $\zeta_k t^k \zeta$  of  $t^k$ . So, when you differentiate that with respect to  $x^n$  so, you get a  $k$ , a factor of  $k$  will come out in this expression. So, now you look

at the we estimate so, this one is fine, we can pass to the limit, there is no problem, here you have  $k$  which tends to infinity and you have some  $Zeta\ k\ dash$ , etcetera.

So, let us look at that integral, integral over  $R_n$  plus of  $k\ u_x$  which comes from here into  $\Psi\ x\ Zeta\ dash\ k\ x_n\ dx$ . So, this is one of the two terms on the left hand side and now  $\Psi$  of  $x\ dash\ 0$  is 0, because now if you put, what is the definition of  $\Psi$ ? It is  $\Phi$  of  $x\ dash\ x_n$  minus  $\Phi$  of  $x\ dash\ minus\ x_n$ .

So, if you put  $0\ x_n$  equal to 0 then these two will get cancelled so, we get  $\Psi$  of  $x\ dash\ 0$  is 0. So, by the mean value theorem you have that  $Mod$  of  $\Psi$  of  $x\ dash\ x_n$  will be lesser than equal to some constant times  $Mod\ x_n$ , where  $C$  is a positive constant depending on the bound so, depending on the bound for derivatives of  $\Phi$ .

$\Phi$  is the  $C\ infinity$  function with compact support so, it uniformly bounded in  $R_n$  so, I do not have to worry about any dependence on  $x\ dash$  and therefore this thing. And also,  $Zeta\ dash$  is a bounded function which is nonzero, only between 1 and 2 so,  $Zeta$  is 0 here up to 1 and then  $Zeta\ dash$  and  $Zeta\ dash$  will be 0 again so, it is only between  $t\ equals\ 1$  and  $t\ equals\ 2$  that you have that  $Zeta\ dash$  is nonzero so, everywhere else it is 0. Therefore, if you take the modulus integral over  $R_n$  plus of  $k\ u_x\ \Psi\ x\ Zeta\ dash\ kx_n\ dx$ , I take the modulus this is equal to  $k$  times  $Mod$  integral.

Now, this integral on  $R_n$  plus I am going to restrict it, it is actually the integral in support of the  $\Phi$  intersection of  $1\ by\ k\ less\ than\ x_n$ , less than  $2\ by\ k$ . Because, only in that range you have that  $Zeta\ dash$  is nonzero so,  $Zeta\ dash\ kx_n$  will be 0 only between 1 and 2 and therefore,  $x_n$  must be between  $1\ by\ k$  and  $2\ by\ k$  so, if you that, and you have  $u_x\ \Psi\ x\ Zeta\ dash\ kx_n\ dx$ .

(Refer Slide Time: 24:35)

$$\leq kC \int_{\text{supp}(\phi) \cap \{\frac{1}{k} \leq x_N \leq \frac{2}{k}\}} |u(x)| |x_N| dx$$

$$\leq 2C \int_{\text{supp}(\phi) \cap \{\frac{1}{k} \leq x_N \leq \frac{2}{k}\}} |u| dx$$

$\rightarrow 0$

$$\int_{\mathbb{R}^d} u(x_N) \frac{\partial \psi}{\partial x_N} dx = - \int_{\mathbb{R}^d} \frac{\partial u}{\partial x_N} \psi dx$$

$$\Rightarrow \frac{\partial u}{\partial x_N} = \left( \frac{\partial \psi}{\partial x_N} \right)' \quad \text{where}$$

$$\Rightarrow \frac{\partial u}{\partial x_N} = \left( \frac{\partial \psi}{\partial x_N} \right)' \quad \text{where}$$

$$\psi(x_N) = \begin{cases} \psi(x_N) & x_N > 0 \\ -\psi(x_N) & x_N < 0 \end{cases}$$

$$\Rightarrow \psi \in L^p(\mathbb{R}^d) \text{ if } u \in L^p(\mathbb{R}^d)$$

$$\int_{\mathbb{R}^d} \frac{\partial u}{\partial x_N} \psi = 2 \int_{\mathbb{R}^d} u \frac{\partial \psi}{\partial x_N}$$

$$\int_{\mathbb{R}^d} \frac{\partial u}{\partial x_N} \psi = 2 \int_{\mathbb{R}^d} u \frac{\partial \psi}{\partial x_N}$$

$$\leq kC \int_{\text{supp}(\phi) \cap \{\frac{1}{k} \leq x_N \leq \frac{2}{k}\}} |u(x)| |x_N| dx \leq 2C \int_{\text{supp}(\phi) \cap \{\frac{1}{k} \leq x_N \leq \frac{2}{k}\}} |u| dx \rightarrow 0.$$

because; the major of this domain of integration goes to 0.

Because, it support of Phi is a compact set and you are intersecting it with a small strip whose width is only 1 by k and therefore you have compact set with strip of 1 by k so, the measure will go to 0 as k goes to 0 and since, Lebesgue integral is absolutely continuous with respect to a absolutely continuous and therefore this has to go to 0.

$$\int_{\mathbb{R}_+^N} u(x) \frac{\partial \psi}{\partial x_N} dx = - \int_{\mathbb{R}_+^N} \psi \frac{\partial u}{\partial x_N} dx.$$

$$\Rightarrow \frac{\partial u^*}{\partial x_N} = \left( \frac{\partial u}{\partial x_N} \right)^*.$$

$$\begin{aligned} v(x', x_N) &= v(x', x_N), \text{ if } x_N > 0, \\ &= -v(x', -x_N), \text{ if } x_N < 0. \end{aligned}$$

$$\Rightarrow v^* \in L^p(\mathbb{R}^N) \text{ if } v \in L^p(\mathbb{R}_+^N), \quad |v^*|^p_{0,p,\mathbb{R}^N} = 2 |v|^p_{0,p,\mathbb{R}_+^N}.$$

$$\left| \frac{\partial u^*}{\partial x_N} \right|^p_{0,p,\mathbb{R}^N} = 2 \left| \frac{\partial u}{\partial x_N} \right|^p_{0,p,\mathbb{R}_+^N}.$$

Cor.  $1 \leq p < \infty$ . The restriction of  $D(\mathbb{R}^N)$  to  $\mathbb{R}_+^N$  is dense in  $W^{1,p}(\mathbb{R}_+^N)$ . In part,  $C^\infty(\mathbb{R}_+^N) \cap W^{1,p}(\mathbb{R}_+^N)$  is dense in  $W^{1,p}(\mathbb{R}_+^N)$ .

Remark. Above proof can be easily adapted for sets like

$$Q_+ = \{x \in \mathbb{R}^N : |x'| < 1, 0 < x_N < 1\}$$

Reflection gives a prolongation (i.e. extension) operator from  $W^{1,p}(Q_+)$  to  $W^{1,p}(Q)$

$$Q = \{x \in \mathbb{R}^N : |x'| < 1, |x_N| < 1\}.$$

**Corollary:**  $1 \leq p \leq \infty$ . The restriction of  $D(\mathbb{R}^N)$  to  $\mathbb{R}_+^N$  is dense  $W^{1,p}(\mathbb{R}_+^N)$ . In particular,

$C^\infty(\mathbb{R}_+^N) \cap W^{1,p}(\mathbb{R}_+^N)$  is dense in  $W^{1,p}(\mathbb{R}_+^N)$ .

**Remark:** so, this proves so, above can be easily adapted for sets like

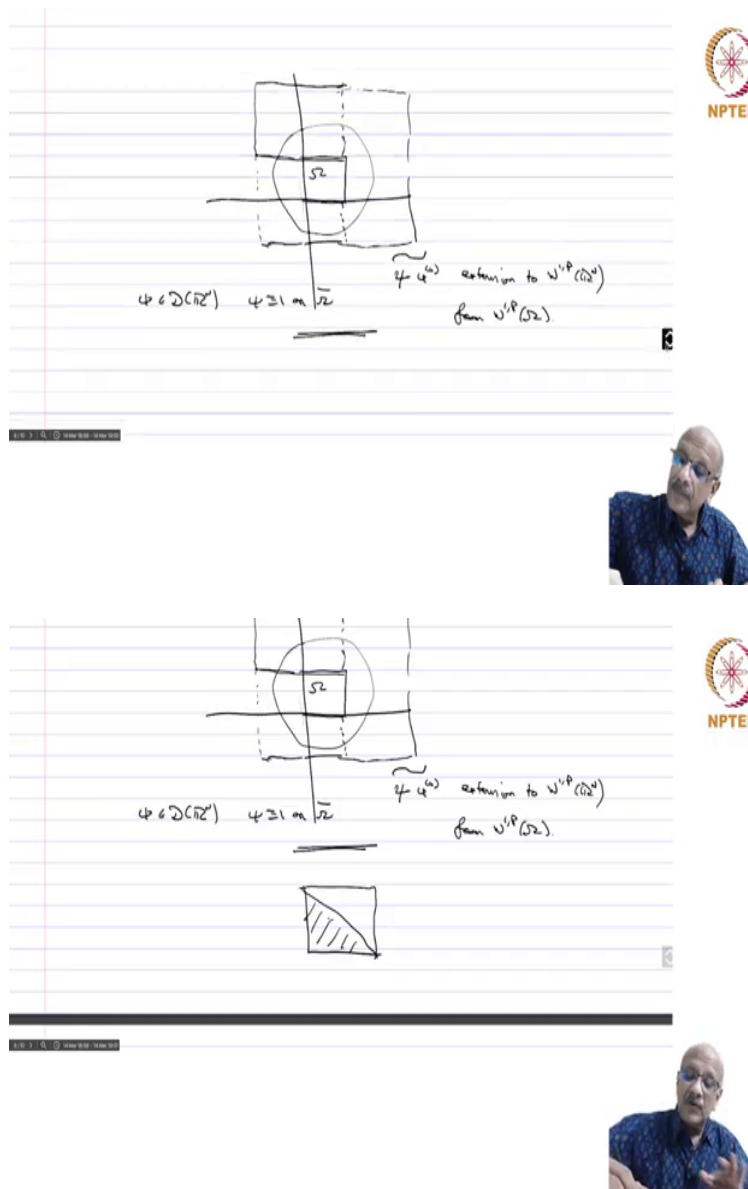

$$Q_+ = \{x \in \mathbb{R}^N : |x'| < 1, 0 < x_N < 1\}.$$

so, reflection gives a prolongation operator or extension operator, a prolongation operator that is extension operator from  $W^{1,p}(Q_+)$  to  $W^{1,p}(Q_-)$ , where  $Q$  is the set

$$Q = \{x \in \mathbb{R}^N : |x'| < 1, |x_N| < 1\}.$$

Now, we can use this trick to define prolongation operators for some sets like.

The diagram illustrates the extension of a function  $\phi$  defined on a square domain  $\Omega$  to a larger rectangle. The square  $\Omega$  is centered at the origin of a coordinate system. The extension is shown as  $\phi^{(n)}$  on the larger rectangle. The NPTEL logo is visible in the top right corner of each slide.

For instance, take the square, suppose I have a square like this now, so this is  $\Omega$  now by reflection on this line, I can extend it to this rectangle. Now, by reflection on this line, I can further extend it to this rectangle. Now, by reflection on this line, I can extend it further. Finally, by reflection on this line, I can extend the function  $\phi$ . So, each time I would have

taken the factor of 2 in the powers of, in the integrals of the derivatives and their functions. So, this 4 times I have done it 1, 2, 3, 4 so, that will be 16 and therefore, that is a constant which is well under control.

Now, what you do is, you take a  $\psi \in D(\mathbb{R}^N)$  with  $\psi = 1$  on  $\overline{\Omega}$  and the neighborhood of it and then you take. So, you have this  $u$  so, I let you call it  $u_4$  the 4 fold extension of  $u$  and then the multiply it by  $\psi$  that will give you an extension. And then extension, outside the square by 0 will give you an extension to  $W^{1,p}(\mathbb{R}_+^N)$  from  $W^{1,p}(\Omega)$ . So, you have  $u$ , you have  $u_1$  which is the extension here, then  $u_2$  which is the extension to the square,  $u_3$  which is the extension to the third one and  $u_4$  is the fourth extension. So, you have 4 and then you multiply by  $\psi$  and therefore, you will get the function which is vanishing outside the compact set and therefore, you will then extend it by 0 nothing no harm is done and it will continue to be equal to  $\Omega$ ,  $u$  inside  $\Omega$ .

So, this way we can define, a use this for instance so, now we can for instance suppose I have a triangle, a right-angled triangle like this, then by reflection on the high part new, so I can extend it to the square and then from the square I know how to extend it to the whole plain. So, I also have an extension operator for the triangle. So, the method of reflection is very useful when you have such flat portions on the boundary to do it.

Next, we will consider a general method for domains so, for what kind of domains we can define extension operators, reflection was very special and now we will see for other kinds of domains where, we will use this reflection idea and the partition of unity and then see how that is to be done.
