Lecture – 02
Linear dependence, independence and Wronskian of functions

Hello friends. Welcome to the lecture on the Linear Dependence, Independence and Wronskian of Functions. First of all we will define what do we mean by homogeneous and non-homogeneous linear differential equations. The n th order linear differential equation is given by a naught x into $y^{(n)}$, $y^{(n)}$ is the n th order of derivative of y with respect to x , plus $a_1(x)y^{(n-1)}$ and so on.

$a_0(x)y^{(n)}$ equal to $r(x)$, where $a_i(x)$, i equal to $0, 1, 2$ and so on up to n are continuous functions and an interval I , and the coefficient of $y^{(n)}$ which is $a_0(x)$ is assumed to be naught 0 for every x in I . So, this equation the n th order linear differential equation given in 1 will be called a homogenous linear differential equation provided $r(x)$ is a identically 0 .

(Refer Slide Time: 01:11)

Definitions

Homogeneous and non-homogeneous linear differential equations:
The n^{th} order linear differential equation is given by

$$a_0(x)y^{(n)}(x) + a_1(x)y^{(n-1)}(x) + \dots + a_n(x)y(x) = r(x), \quad \dots(1)$$

where $a_i(x)$, $i = 0, 1, 2, \dots, n$ are continuous in I and $a_0(x) \neq 0$, for every x in I .

The above equation is called **homogeneous** if $r(x) \equiv 0$, otherwise it is called **non-homogeneous**.

2

And otherwise it will be called a non homogenous linear differential equation. Regarding the homogenous linear differential equation, there is very nice theorem which we call as the superposition principle for homogenous functions.

(Refer Slide Time: 01:29)

Superposition principle for homogeneous equations

Theorem 1. Let y_1, y_2, \dots, y_k be solutions of the homogeneous n^{th} order differential equation (1) on an interval I . Then, the linear combination

$$y = c_1 y_1(x) + c_2 y_2(x) + \dots + c_k y_k(x),$$

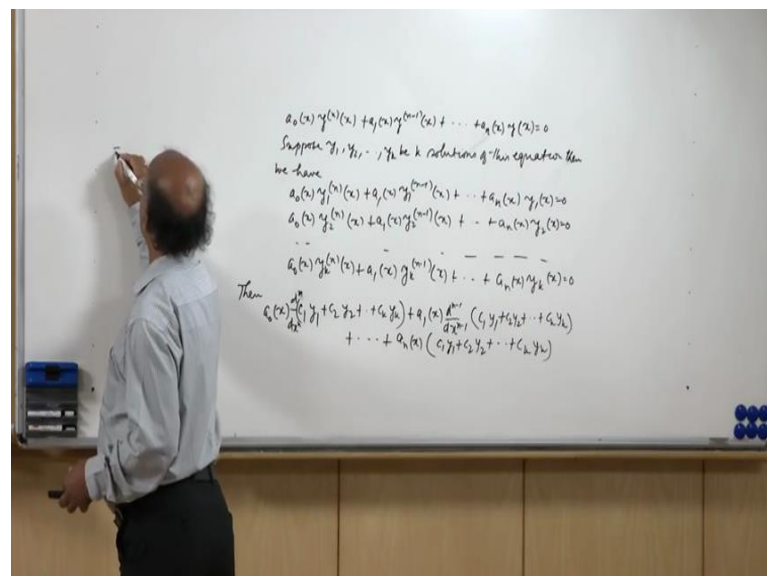

where the $c_i, i = 1, 2, \dots, k$ are arbitrary constants, is also a solution on I .

It says that let y_1, y_2, y_k be k solutions of the homogeneous n^{th} order differential equation (1); we are considering homogeneous equation here which means that we are taking $R(x)$ to be identically 0.

So, in the case of homogeneous linear differential equation given by (1), if we have k solutions y_1, y_2, y_k then their linear combination; linear combination means the function $c_1 y_1(x) + c_2 y_2(x) + \dots + c_k y_k(x)$, where c_1, c_2, \dots, c_k are arbitrary constants is also a solution on I , it is very simple we can easily prove this.

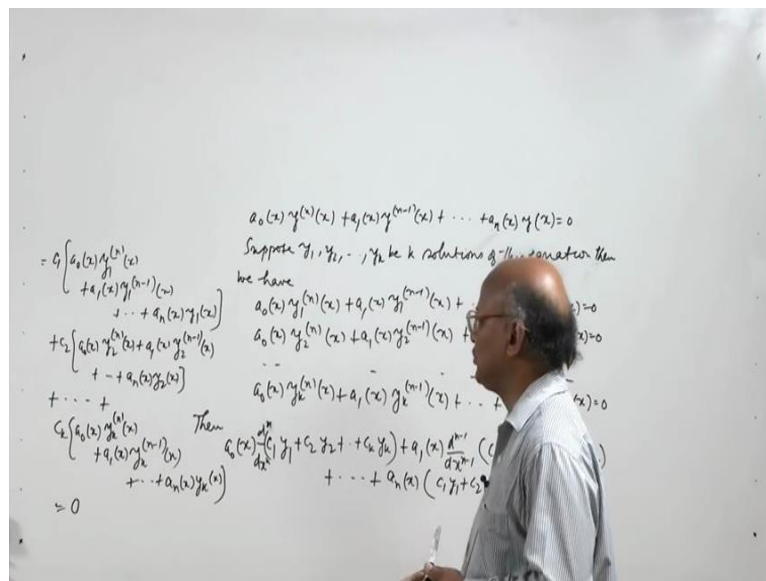

(Refer Slide Time: 02:19)

So, suppose let us see how we can prove this our homogenous differential equation is a naught x into y n x, plus a 1 x into y n minus 1 x and so on; a naught a n x into y x equal to 0, this is our homogenous linear differential equation. So, let suppose y 1, y 2 and so on y k be k a solution of this equation, this equation then we will have a naught x, into y 1 n x, plus a 1 x y 1 n minus 1 x and so on a n x into y 1 x equal to 0. Similarly for the function y 2 x we will have as we can write in a similar manner the kth equation a naught x, y k n x plus a 1 x into y k n minus 1 x and so on, a n x, y k n, y k x equal to 0. From these k equations then we can show that c 1 y 1 plus c 2 y 2 and so on c k y k is also solution of this homogenous equation.

So, then a naught x into c 1, y 1 plus c 2, y 2 and so on c k y k the kth derivative of this that is d k; no we have here nth derivative. So, nth derivative of this a naught x into nth derivative of c 1, y 1 plus c 2 y 2 and so on c k y k plus a 1 x into n minus oneth derivative of c 1, y 1 plus c 2, y 2 and so on c k, y k. And the last term a n x into c 1, y 1 plus c 2, y 2 and so on c k, y k; this is equal to a naught x.

(Refer Slide Time: 05:47)

Now another derivative of c 1, y 1 plus c 2, y 2 plus c k, y k will be c 1 times nth derivative of y 1, plus c 2 times nth derivative of y 2, plus c k times nth derivative of y k similarly here n minus 1 of the derivative of this linear combination will be c 1 times n minus derivative of y 1, plus c 2 times n minus 1 derivative of y 2 and so on c k times n minus oneth derivative of y k.

So, we can write it as equal to c_1 times a naught x , n minus n th derivative of y_1 , this plus c_2 times a naught x , into n n th derivative of y_2 , plus a $1 \times n$ minus one th derivative of y_2 and so on; a $n \times$, $y_2 \times$ and so on we can write c_k times a naught x , $y_k \times n \times$ plus a $1 \times$, $y_k \times n$ minus $1 \times$ and so on a $n \times$, $y_k \times$. Now since y_1, y_2, y_k are solutions of the given equation homogenous equation, so this is 0, this is 0 and this is 0 and therefore, we have 0. So, c_1, y_1 plus c_2, y_2 and so on c_k, y_k is also a solution of the homogenous linear differential equation; so this known as the superposition principle for homogenous equations.

Now, let us define linear dependence independence of functions, it is a very important concept in the solution of differential equations.

(Refer Slide Time: 08:13)

General definitions of linear dependence and independence:
A set of functions $y_1(x), y_2(x), \dots, y_n(x)$ is called **linearly dependent** on an interval I if there exist constants c_1, c_2, \dots, c_n not all zero such that

$$c_1 y_1(x) + c_2 y_2(x) + \dots + c_n y_n(x) = 0.$$

A set of functions $y_1(x), y_2(x), \dots, y_n(x)$ is called linearly independent on an interval I if the only constants for which

$$c_1 y_1(x) + c_2 y_2(x) + \dots + c_n y_n(x) = 0,$$

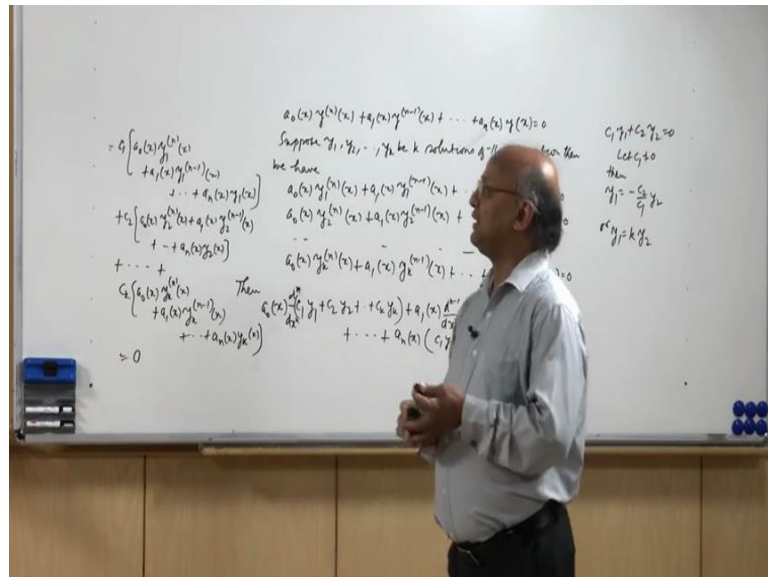

for every x in I , are $c_1 = c_2 = \dots = c_n = 0$.

So, a set of functions y_1, y_2, y_n will be called linearly dependent on an interval i , if we can find some constants c_1, c_2, c_n not all 0; that means, at least one constant here must be a non-zero constant such that c_1, y_1 plus c_2, y_2 and so on c_n, y_n equal to 0. So, if the n functions are not linearly dependent then they will be called linearly independent. And for that we have the definition that c_1, y_1 plus c_2, y_2 and so on c_n, y_n is equal to 0 will always imply that c_1 equal to 0, c_2 equal to 0 and so on c_1, c_n equal to 0; that means, we cannot find any set of n constant c_1, c_2, c_n not all 0 such that c_1, y_1 plus c_2, y_2 plus c_n, y_n equal to 0, which further which in other words it means that the n

functions y_1, y_2, \dots, y_n will be called linearly independent if and only if $c_1 = 0$ whenever $c_1 y_1 + c_2 y_2 + \dots + c_n y_n = 0$, it will always imply that c_1, c_2, \dots, c_n all are zeroes.

Now, let us see how we can check the linear dependence/independence of functions. From the definition of linear dependence it follows that you take n equal to 2 here; that means, if you take 2 functions y_1, x and y_2, x then they will be linearly dependent provided $c_1 y_1 + c_2 y_2 = 0$. There both c_1 and c_2 where c_1, c_2 both are not 0; that means, at least one of them is non 0. So, suppose c_1 is nonzero then $c_1 y_1 + c_2 y_2 = 0$ can be written as.

(Refer Slide Time: 09:57)

So, let c_1 be non-zero then we can divide by c_1 and write $y_1 = -c_2/c_1 y_2$. So, $c_2/c_1 y_2 + c_2 y_2 = 0$ is a constant so we can write $r y_1 = k y_2$, which will mean that y_1 is a scalar multiple of y_2 .

(Refer Slide Time: 10:26)

In particular, two functions $y_1(x)$ and $y_2(x)$ are called linearly dependent on some interval I if they are proportional on i.e, $y_1 = k y_2$ or $y_2 = k y_1$ holds for all x on I .

If the functions $y_1(x)$ and $y_2(x)$ are not proportional on I , they are called **linearly independent** on I .

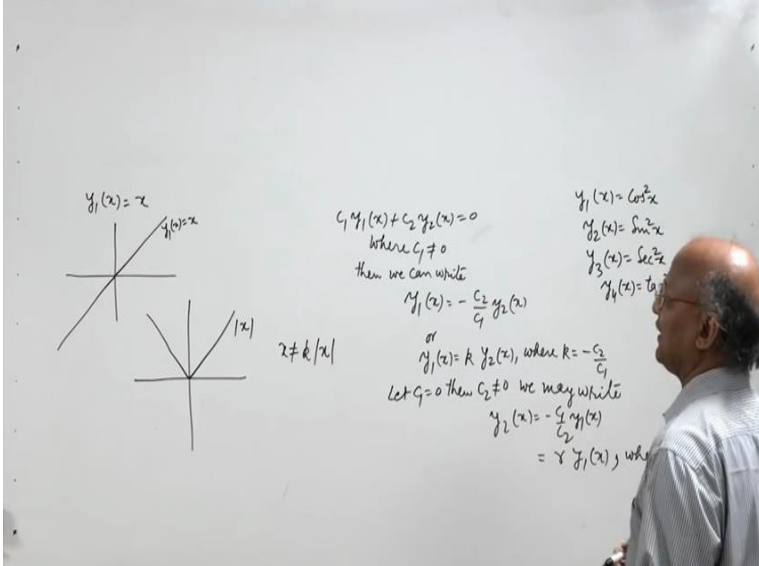

Example 1. $y_1(x) = \sin 2x$ and $y_2(x) = \sin x \cos x$ are linearly dependent on $(-\infty, \infty)$.

Example 2. $y_1(x) = x$ and $y_2(x) = |x|$ are linearly independent on $(-\infty, \infty)$.

5

In particular the 2 functions let us say y_1 and y_2 , they will be called linearly dependent on some interval I if they are proportional. That is y_1 is k times y_2 or y_2 is equal to k times y_1 because when we take n equal to 2 in this definition, then if y_1 and y_2 are linearly dependent then $c_1 y_1 + c_2 y_2 = 0$ where c_1 and c_2 are not both zeros.

(Refer Slide Time: 10:58)

$c_1 y_1(x) + c_2 y_2(x) = 0$
 where $c_1 \neq 0$
 then we can write
 $y_1(x) = -\frac{c_2}{c_1} y_2(x)$
 or
 $y_1(x) = k y_2(x)$, where $k = -\frac{c_2}{c_1}$
 Let $c_1 = 0$ then $c_2 \neq 0$ we may write
 $y_2(x) = -\frac{c_1}{c_2} y_1(x)$
 $= \gamma y_1(x)$, where

$y_1(x) = \cos^2 x$
 $y_2(x) = \sin^2 x$
 $y_3(x) = \sec^2 x$
 $y_4(x) = \tan^2 x$

So, suppose $c_1 y_1 + c_2 y_2 = 0$; where let us say c_1 is not equal to 0, then we can write $y_1 = -\frac{c_2}{c_1} y_2$. Minus c_2 over c_1 is some

constant. So, we can write $y_1(x)$ equal to some constant k times $y_2(x)$, where k is equal to $\frac{-c_2}{c_1}$. So, y_1 is a constant multiple y_2 , if instead of c_1 let us say c_2 is equal to 0, c_2 is not equal to 0. Let us say c_1 is equal to 0 then c_2 must be not equal to 0. So, if c_2 is not equal to 0, then we can divide this equation by c_2 , and write we may write y_2 is equal to $\frac{-c_1}{c_2}$ into $y_1(x)$. So, this will be some constant let us say some constant r , so r into $y_1(x)$, where r is equal to $\frac{-c_1}{c_2}$. So, in either case y_1 and y_2 will be proportional to each other; one will be a constant multiple of the other.

Now, if y_1, y_2 are not proportional on i then they will be linearly independent on i . For example, if you take the function $y_1(x)$ equal to $\sin^2(x)$, and $y_2(x)$ equal to $\sin(x)\cos(x)$ then we know that $\sin^2(x)$ is $2\sin(x)\cos(x)$. So, we can write $y_1(x)$ to be equal to 2 times $y_2(x)$, which means that y_1 is a scalar multiple of y_2 and so y_1 and y_2 will be linearly dependent on the interval $-\infty$. Now in example 2; suppose we take the function $y_1(x)$ equal to x and $y_2(x)$ equal to $\text{mod}(x)$, then we can see from the graph that they are not linearly dependent on the interval $-\infty$ to ∞ . $y_1(x)$ is equal to x the graph of $y_1(x)$ equal to x is this line, this is $y_1(x)$ is equal to x and the graph of $y_2(x)$ equal to $\text{mod}(x)$, this is $y_2(x)$ graph. So, we can see that x is not a scalar multiple of $\text{mod}(x)$. If x is a suppose if x is equal to $\text{mod}(x)$ then x is not a equal to some constant times $\text{mod}(x)$, because $\text{mod}(x)$ is equal to x when x is positive, and $-x$ when x is negative. So, x and $\text{mod}(x)$ cannot be equal for some constant k .

Therefore, they are both linearly independent on the interval $-\infty$ to ∞ . Now we take the case of say 4 functions $y_1(x)$ equal to $\cos^2(x)$, $y_2(x)$ equal to $\sin^2(x)$, $y_3(x)$ equal to $\sec^2(x)$, and $y_4(x)$ equal to $\tan^2(x)$, we can see that they are linearly independent on the interval $-\frac{\pi}{2}$ to $\frac{\pi}{2}$.

(Refer Slide Time: 14:27)

Example 3: The functions $y_1(x) = \cos^2x$, $y_2(x) = \sin^2x$, $y_3(x) = \sec^2x$ and $y_4(x) = \tan^2x$ are linearly dependent on the interval $(-\pi/2, \pi/2)$.

Example 4: $y_1(x) = e^x$, $y_2(x) = e^{2x}$, $y_3(x) = e^{3x}$ are linearly independent on $(-\infty, \infty)$.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 6

So, this interval is very important; here because you can see that this is sec square x is 1 over cos square x. So, if you go beyond minus pi by 2 to pi by 2, then what will happen is that sec square x is 1 over cos square x, it will be 0 at pi by 2 and minus pi by 2. So, Sec Square will not be defined. So, we can find ourselves and more over in tan square x will not be defined at pi by 2 n minus pi by 2. So, we will consider the interval minus pi by 2 pi by 2.

Now, here let us see we have y_1 equal to cos square x, y_2 x equal sin square x, y_3 x equal to sec square x, and y_4 x equal to tan square x. We have to show that they are linearly dependent on the interval minus pi by 2 to pi by 2. So, what we do is we have to find our constant c_1, c_2, c_3, c_4 such that which are not all zeros such that c_1, y_1 plus c_2, y_2 plus c_3, y_3 and c_4, y_4 is equal to 0. So, we have to find constants c_1, c_2, c_3 and c_4 not all 0 such that c_1, y_1 plus c_2, y_2 plus c_3, y_3 plus c_4, y_4 is equal to 0.

(Refer Slide Time: 16:04)

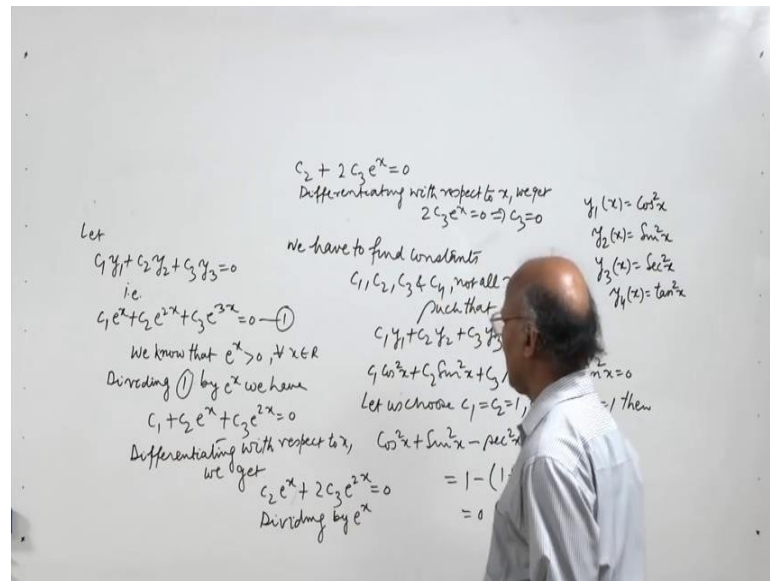

So, what we do is $c_1 y_1 + c_2 y_2 + c_3 y_3 + c_4 y_4 = 0$. y_1 is $\cos^2 x$. So, c_1 times $\cos^2 x$ then c_2 times $\sin^2 x$, then c_3 times $\sec^2 x$, and then c_4 times $\tan^2 x$. We know that $\sec^2 x$ is $1 + \tan^2 x$. So, and we moreover we know that $\sin^2 x + \cos^2 x = 1$. So, let us choose $c_1 = c_2 = 1$. So, that we have here $\cos^2 x + \sin^2 x$ that is 1, and here we will have c_3 into $1 + \tan^2 x$.

So, let us take c_3 to be minus 1. So, let us take c_1, c_2 be equal to 1 c_3 equal to minus 1 and c_4 equal to 1; then we can see that $\cos^2 x + \sin^2 x - \sec^2 x + \tan^2 x$; will be equal to this is $1 - 1 + \tan^2 x + \tan^2 x$. So, this will be equal to 0. So, we are able to find the constants c_1, c_2, c_3, c_4 not all zeroes such that $c_1 y_1 + c_2 y_2 + c_3 y_3 + c_4 y_4 = 0$. So, they are linearly dependent on the interval $-\pi/2$ to $\pi/2$.

And the example 4: we consider $y_1(x) = e^x$, $y_2(x) = e^{2x}$, $y_3(x) = e^{3x}$. Let us show that they are linearly independent on the interval $-\infty$. So, in order to prove that they are linearly independent, we have to show that whenever we write $c_1 y_1 + c_2 y_2 + c_3 y_3 = 0$ it will always imply that c_1, c_2, c_3 all are zeroes.

(Refer Slide Time: 18:51)

So, let us say let $c_1 y_1 + c_2 y_2 + c_3 y_3 = 0$; that is $c_1 e^x + c_2 e^{2x} + c_3 e^{3x} = 0$. Our aim is to prove that c_1, c_2, c_3 all are zeros. Now we know that e^x is always positive for every real x , we know that $e^x > 0$ for all x belonging to \mathbb{R} .

So, what we do is we divide this equation by e^x . So, dividing the equation 1 by e^x , we have $c_1 + c_2 e^x + c_3 e^{2x} = 0$; again divide this equation by e^x . So, we have $c_1 + c_2 e^x + c_3 e^{2x} = 0$, now what we will do is let us differentiate this equation, this equation holds for every x belonging to \mathbb{R} . So, differentiating this equation with respect to x we have we get this is $0, c_2 e^x + 2c_3 e^{2x} = 0$.

So, we get this. Now what we do is we again divide by e^x . So, dividing by e^x , we will get $c_2 + 2c_3 e^x = 0$, again this equation is valid for every x belonging to \mathbb{R} . So, differentiating with respect to x , we get $2c_3 e^x = 0$. Now e^x is always positive; so this means that $c_3 = 0$, when $c_3 = 0$ from here we get $c_2 = 0$ and then $c_3 = 0$ and $c_2 = 0$ give us $c_1 = 0$. So, we get c_1, c_2, c_3 all are zeros. So, e^x, e^{2x}, e^{3x} are linearly independent functions on minus infinity to infinity interval.

(Refer Slide Time: 21:54)

Wronskian: Suppose each of the functions $y_1(x), y_2(x), \dots, y_n(x)$ possesses at least $(n-1)$ derivatives. The following determinant is called the Wronskian of these n functions :

$$W(y_1, y_2, \dots, y_n) = \begin{vmatrix} y_1 & y_2 & \dots & y_n \\ y_1' & y_2' & \dots & y_n' \\ \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots \\ y_1^{(n-1)} & y_2^{(n-1)} & \dots & y_n^{(n-1)} \end{vmatrix}$$

 IIT ROORKEE
  NIPER ONLINE CERTIFICATION COURSE
 7

Now, let us consider the n functions. So, suppose we have n function $y_1(x), y_2(x), \dots, y_n(x)$ we have seen while doing these examples that it is not easy to check the linear dependence independence by the by finding the constant c_1, c_2, c_3, c_4 and so on to. So, it is, but. So, there is another process by which we can check the linear dependence independence of n functions. So, if suppose we have n functions y_1, y_2, y_n which possess say at least n minus 1 derivative with respect to x , then we will check the value of this determinant.

This is n th order determinant which we denote by $W(y_1, y_2, y_n)$ and call is at the Wronskian of these call is at the Wronskian of these n functions. So, in the first row we have y_1, y_2, y_n second row has first order derivatives of y_1, y_2, y_n and the last row has n minus oneth order derivatives of y_1, y_2, y_n . We will see that this n th order determinant in the case of in other in the case of n function y_1, y_2, y_n which are the solutions of the homogenous linear n th order differential equation, they will be linearly independent if and only if the Wronskian of this n functions is not equal to 0 on the interval i .

So, it is easy to check the value of the Wronskian of the n solution of the n th order linear differential equation to decide whether they are linearly dependent or independent; let us see how we prove this result.

(Refer Slide Time: 23:12)

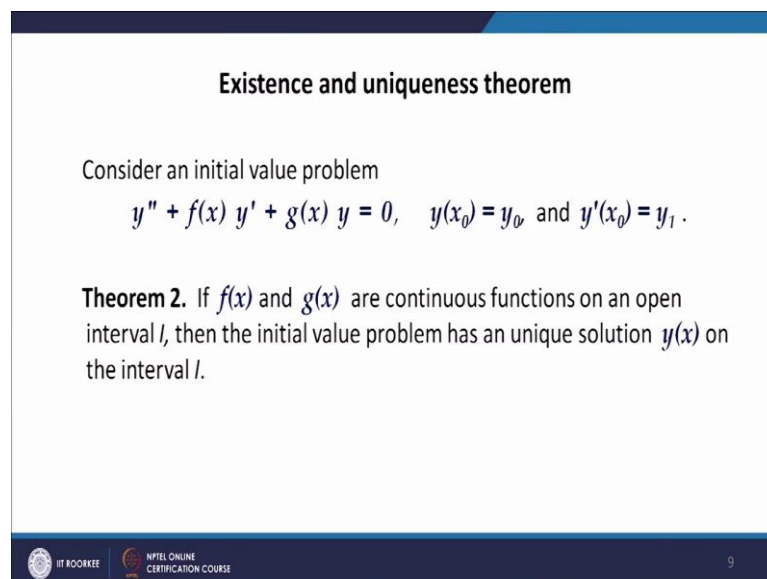

In order to check whether n solutions y_1, y_2, \dots, y_n of a homogeneous linear n^{th} order differential equation are linearly independent, one can calculate the Wronskian of these n functions.

8

So, let us consider an initial value problem; here this is called initial value problem because we have a second order differential equation with 2 conditions y at x naught equal to y naught, y dash at x naught equal to y_1 which are called the initial conditions.

(Refer Slide Time: 23:46)

Existence and uniqueness theorem

Consider an initial value problem

$$y'' + f(x)y' + g(x)y = 0, \quad y(x_0) = y_0, \text{ and } y'(x_0) = y_1.$$

Theorem 2. If $f(x)$ and $g(x)$ are continuous functions on an open interval I , then the initial value problem has a unique solution $y(x)$ on the interval I .

9

So, second order differential equation of with 2 initial conditions is called as a initial value problem. So, let us consider this initial value problem, if $f(x)$ and $g(x)$ are continuous functions here on an open interval I , then this initial value problem has in unique solution by x on the interval I , this is extended result. So, we shall make use of this result.

(Refer Slide Time: 24:28)

Theorem 3. Suppose that the coefficients $f(x)$ and $g(x)$ of the differential equation

$$y'' + f(x)y' + g(x)y = 0, \quad \dots (2)$$

are continuous on an open interval I . Then any two solutions of this equation on I are linearly dependent on I if and only if their Wronskian W is zero for some $x = x_0$ in I . (If $W=0$ for $x=x_0$ then $W \equiv 0$ on I .)

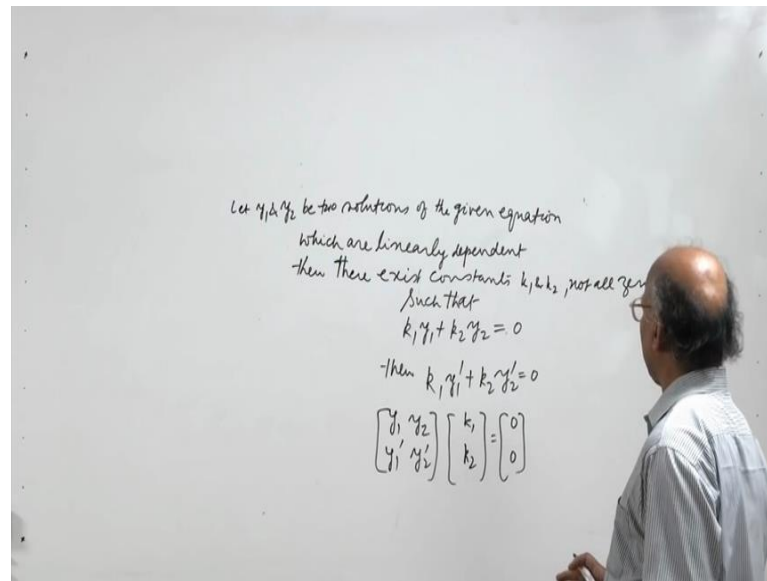

Continuity assumption in the preceding theorem can not be omitted.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 10

So, let us suppose that the coefficients effects in $g(x)$ of this differential equation or continuous in an open interval I , then any 2 solutions of this equation or linearly dependent on the interval I if and only if. The Wronskian is 0 for some x equal to x_0 ; if $W=0$ for some x equal to x_0 then w is identically 0 on an I . So, here this is a homogenous a linear differential equation, the 2 functions y_1 and y_2 let us say the 2 solutions y_1 and y_2 of this differential equation will be linearly dependent if and only if their Wronskian is 0 identically 0. So, this result can be extended to n functions we are proving it for n equal to 2.

So, in the case of n th order differential equation, the n solutions will be linearly dependent if and only if their Wronskian is 0. So, we will do it for simple for simplicity we will do it for n equal to 2. So, let us see how we prove this result. So, let us assume that.

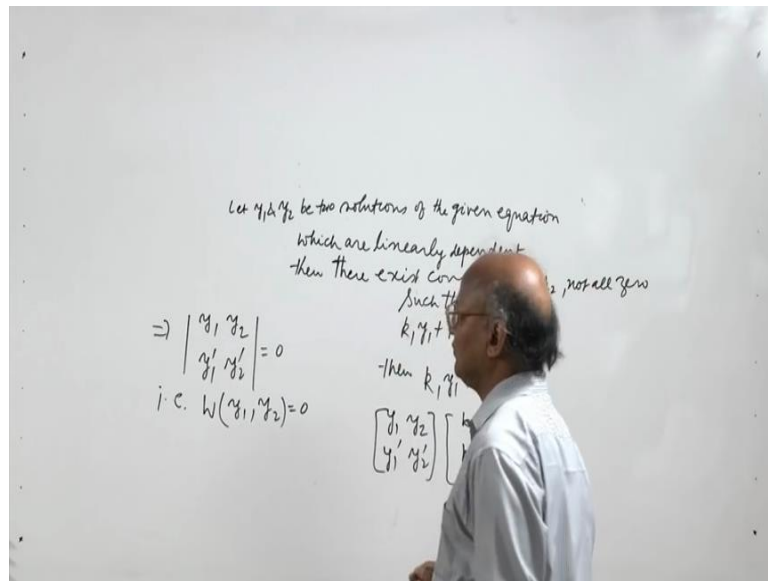

(Refer Slide Time: 25:32)

Let us assume that y_1 and y_2 be 2 solutions of the equation 2, which are linearly dependent. Let y_1 and y_2 be 2 dependent be 2 solutions of the given equation which are linearly dependent. Then why the definition of linear dependence then there exists constants k_1 and k_2 say not all 0, such that such that $k_1 y_1 + k_2 y_2$ is equal to 0. So, by the definition of linear dependence we arrive at 2 constants k_1 and k_2 , which are not all which are not both 0. So, that $k_1 y_1 + k_2 y_2$ is the equal to 0. We have to prove that the Wronskian of the functions y_1 and y_2 is equal to 0, for some x equal to x naught in I . So, we can see from here that then $k_1 y_1 + k_2 y_2$ is equal to 0, differentiating this equation with respect to x we have $k_1 y_1' + k_2 y_2'$ is equal to 0.

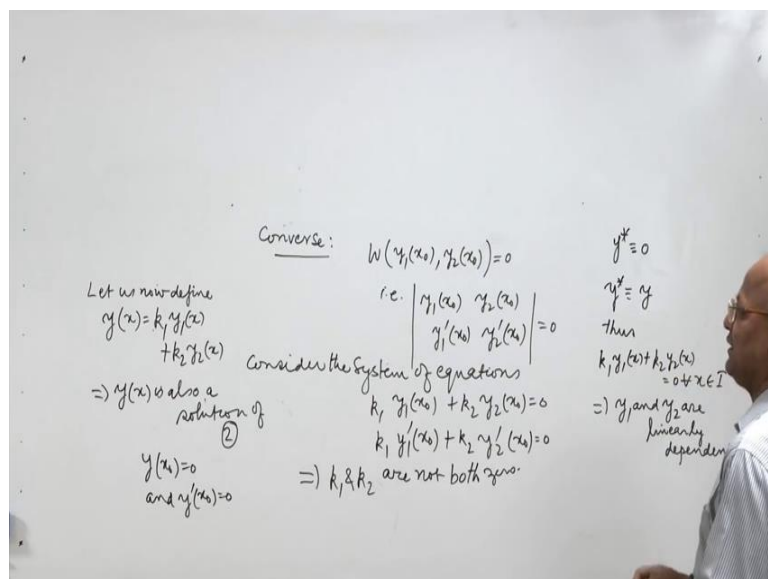

So, from these 2 equations what we have y_1, y_2, y_1', y_2' , this coefficient matrix into k_1, k_2 . So, this is a homogenous system of linear equations where k_1, k_2 are not both 0 therefore, determinant of this matrix must be 0.

(Refer Slide Time: 28:10)

So, these imply that modulus over this $y_1, y_2, y_1 \text{ dash}, y_2 \text{ dash}$ must be equal to 0. So, the determinant of the functions $y_1, y_2, y_1 \text{ dash}, y_2 \text{ dash}$ is equal to 0, that is the Wronskian of the function y_1, y_2 is equal to 0. So, this proves that whenever the 2 functions y_1, y_2 solutions of the equation are linearly dependent, then their Wronskian is 0. So, it is 0 for some x naught.

(Refer Slide Time: 28:52)

Now, let us see we can prove the converse. So, for the converse let us assume that. So, let us assume that the Wronskian W is 0 for some x equal to x naught in I . So, W at

$W(y_1(x), y_2(x)) = 0$, that is $y_1(x), y_2(x)$ are linearly dependent at $x = x_0$. We are given that the two solutions y_1 and y_2 of the equation (2) are such that the Wronskian w is 0 for some x equal to x_0 . So, from that we have this determinant equal to 0; now let us consider the system of equations, $k_1 y_1(x_0) + k_2 y_2(x_0) = 0$, let us consider this system of equations. So, here we see since the determinant of k_1, k_2 is not 0, since the determinant of $y_1(x_0), y_2(x_0)$ is equal to 0; this homogenous system of linear equations implies that k_1 and k_2 are not both 0. So, this implies that k_1 and k_2 are not both 0.

And now then let us define $y(x) = k_1 y_1(x) + k_2 y_2(x)$. Since y_1 and y_2 are solution of the equation (2), and equation (2) is homogenous equation by the super cheap position principle, it follows that $k_1 y_1 + k_2 y_2$ is also a solution of equation (2). So, $y(x)$ is also a solution of equation (2). Now from these equations it follows that $y(x_0) = 0$, if you put $x = x_0$ here $k_1 y_1(x_0) + k_2 y_2(x_0) = 0$. So, $y(x_0) = 0$ and $y'(x_0) = 0$. So, $y(x_0) = 0$ and $y'(x_0) = 0$. So, $y(x_0) = 0$ and $y'(x_0) = 0$. So, now, what do we see that $y(x)$ is a solution of equation (2), and also $y(x_0) = 0$ and $y'(x_0) = 0$.

Now, another solution of equation (2) is $y^* = 0$ solution; that is 0 solution satisfies the equation (2), and also $y^* = 0$ satisfies $y^*(x_0) = 0$ and $y^{*\prime}(x_0) = 0$. So, this solution satisfies equation (2) along with the 2 conditions that at $x = x_0$ it is 0 and its derivative is also that are $x = x_0$. Now let us apply the theorem uniqueness theorem adjutancy uniqueness theorem; this theorem tells us that in when we have this homogenous equation or we have this initial value problem where $y(x_0) = y_0$, $y'(x_0) = y_1$, then the solution is unique, the initial value problem has unique solution. So, the both the solutions $y(x)$ and this solution must be identical and therefore, y^* must be equal to y . So, we can say that y must be identically 0. So, $k_1 y_1(x) + k_2 y_2(x) = 0$ for all x belonging to I . So, by the uniqueness theorem it follows that $k_1 y_1 + k_2 y_2$ is equal to 0 for all x belonging to I , and k_1, k_2 are not both 0 this implies that y_1 and y_2 are linearly dependent y_1 and y_2 are linearly dependent.

Now, y_1 and y_2 ; so y_1 and y_2 are linearly dependent, so whenever Wronskian w is 0 for some x equal to x naught, it we have proved that y_1 and y_2 are linearly dependent. Now let us apply the proof of the first part, in the proof of the first part we have shown that whenever 2 solutions are linearly dependent then W is identically 0. So, here y_1 and y_2 are linearly dependent, now use the proof of a first part to say that W is 0, W is identically 0 on I .

So now, use now using the proof of the necessity part we have W is identically 0. So, this theorem tells us that whenever 2 solutions of equation 2 are linearly dependent, then W is identically 0 on I . Here the continuity assumption in this theorem cannot be omitted, let us see why the continuity junction cannot be dropped here this is evident from this example. Just take y_1 x equal to x cube for all real x and y_2 x equal to x cube when x is greater than or equal to 0 and minus x cube when x is less than 0.

(Refer Slide Time: 35:41)

Example. Let $y_1(x) = x^3$ for all real x and $y_2(x) = x^3$, when $x \geq 0$ and $-x^3$ when $x < 0$. These functions are solutions of the differential equation

$$y'' - (3/x)y' + (3/x^2)y = 0$$

for all x , the functions $y_1(x)$ and $y_2(x)$ are linearly independent on the x -axis, although their Wronskian is identically zero. This does not contradict Theorem 3 because the coefficients in the above differential equation are not continuous at $x = 0$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

You can easily check that y_1 x equal to x cube satisfies this equation for all real x , and y_2 x equal to x cube when x greater than or equal to 0, and minus x cube when x less than 0; they also satisfy this second order differential equation for all x . So, both y_1 and y_2 are now moreover we can see that y_1 x is x cube, for ordinal x while y_2 x is x cube when x is greater than or equal to 0, minus x cube when x is less than 0.

So, they are both linearly independent on the x axis one is not a scalar multiple of the other. Although their Wronskian identically 0, we can easily check that Wronskian of y_1

and y_2 is equal to is identically 0. So, this does not contradict with theorem 3; here we are seeing that although the function y_1, y_2 are linearly independent their Wronskian turns out to be identically 0. This step this example does not contradict theorem 3 because the coefficients in this equation $f(x)$ is minus $3y(x)$, and $g(x)$ is $3y(x)^2$ they are not continuous at x equal to 0. So, because of the fact that they are not continuous at x equal to 0, it does not contradict theorem 3.

Criterion for linear independence:

Let us consider that $a_1(x), a_2(x), \dots, a_n(x)$ are the continuous functions and let y_1, y_2, \dots, y_n be n solutions of the homogeneous linear n^{th} order differential equation

$$y^{(n)}(x) + a_1(x)y^{(n-1)}(x) + \dots + a_n(x)y(x) = 0, \quad \dots(3)$$

on an interval I . Then, the set of solutions is linearly independent on I if and only if $W(y_1, y_2, \dots, y_n) \neq 0$ for every x in I .

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 12

Now, when suppose we consider the n th order linear homogenous linear differential equation, we are a $1 \times n$, $a_n \times n$ are continuous functions then the then the result which we proved for n equal to 2; this result can be generalized to n functions. So, we have the set of solutions n solutions y_1, y_2, \dots, y_n is linearly independent I and I if and only if $W(y_1, y_2, \dots, y_n)$ is not equal to 0 for every x in I .

So, that can be generalized to this n th order homogenous linear differential equation. Now a set y_1, y_2, \dots, y_n of n linearly independent solutions of the homogenous n th order differential equation on an interval I is called a fundamental set of solutions, and it can be shown that there exists a fundamental set of solutions for the homogenous linear n th order differential equation on an interval I .

(Refer Slide Time: 37:57)

Theorem 4. There exist a fundamental set of solutions for the homogeneous linear n^{th} order differential equation (2) on an interval I .

Example: The set of solutions $\sin 2x$, $\cos 2x$, e^{2x} form a fundamental system of solutions of the differential equation

$$y''' - 2y'' + 4y' - 8y = 0.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

For as an example we can consider the set of solutions $\sin 2x$, $\cos 2x$, e^{2x} . These 3 functions we can easily check that, they are solutions of this third order homogenous linear differential equation, and they form a fundamental set. Fundamental set means we have to show that the 3 functions are linearly independent, which we can easily show by using the Wronskian.

So, let us consider the Wronskian of these 3 functions, and show that these 3 functions are linearly independent and so form a fundamental set.

(Refer Slide Time: 38:43)

$y_1 = \sin 2x$
 $y_2 = \cos 2x$
 $y_3 = e^{2x}$

then $W(y_1, y_2, y_3) = \begin{vmatrix} \sin 2x & \cos 2x & e^{2x} \\ 2\cos 2x & -2\sin 2x & 2e^{2x} \\ -4\sin 2x & -4\cos 2x & 4e^{2x} \end{vmatrix}$

$= 8e^{2x} \begin{vmatrix} \sin 2x & \cos 2x & 1 \\ \cos 2x & -\sin 2x & 1 \\ -\sin 2x & -\cos 2x & 1 \end{vmatrix}$

So, let us consider the Wronskian of these 3 functions. So, Wronskian so that the function y_1 be equal to $\sin 2x$, y_2 be equal to $\cos 2x$, y_3 be equal to e to the power $2x$, then $W(y_1, y_2, y_3)$ this is equal to e to the power $2x$ times $\sin 2x$, $\cos 2x$, e to the power $2x$. Next row contains the derivatives. So, $2 \cos 2x$, this will be $2 \sin 2x$, then here we will have $2e$ to the power $2x$; and here second order derivatives of each of these functions. So, we have $-4 \sin 2x$, and then here we have $-4 \cos 2x$, here we will have $4e$ to the power $2x$.

Now e to the power $2x$ is strictly positive. So, we can take it for $2x$ out of the last column. So, e to the power $2x$ and then we can take common from e last column and then we take 2 and 4 from the first and second and third row. So, I will have here 8 times, what I have done is I have taken e to the power $2x$ common from the third column, and 2 and 4 from the second and third rows. So, 8 times e to the power $2x$.

(Refer Slide Time: 40:43)

$y_1 = \sin 2x$
 $y_2 = \cos 2x$
 $y_3 = e^{2x}$

$W(y_1, y_2, y_3) = \begin{vmatrix} \sin 2x & \cos 2x & e^{2x} \\ 2 \cos 2x & -2 \sin 2x & 2e^{2x} \\ -4 \sin 2x & -4 \cos 2x & 4e^{2x} \end{vmatrix}$

$= 8e^{2x} \begin{vmatrix} \sin 2x & \cos 2x & 1 \\ \cos 2x & -\sin 2x & 2 \\ 0 & 0 & 2 \end{vmatrix}$

$= 8e^{2x} \cdot 2(-\sin^2 2x - \cos^2 2x) = -16e^{2x} < 0$

Now, let us add first row to the third row. So, we will get here $0, 0$ and we will get here 2 . Now let us expand it by the last row. So, we will have here $8e$ to the power $2x$ into 2 times, $-\sin^2 2x - \cos^2 2x$, which is -1 . So, we get $-16e$ to the power $2x$, which is in fact less than 0 . So, the Jacobian is not 0 and therefore, the 3 functions are linearly independent and so form a fundamental set of solutions of this third order differential equation.

(Refer Slide Time: 41:49)

Theorem 5. Let

$$y = c_1 y_1(x) + c_2 y_2(x) \quad \dots(4)$$

be a general solution of the equation (2) on an open interval I , where the coefficients $f(x)$ and $g(x)$ are continuous. Let $y(x)$ be any solution of equation (2) on I containing no arbitrary constants. Then $y(x)$ is obtained from (4) by assigning suitable value to the constants.

 IIT ROORKEE  NITEL ONLINE CERTIFICATION COURSE 15

Now, this last theorem tells us that if you take y equal to $c_1 y_1(x)$, plus $c_2 y_2(x)$ and it be a general solution of the homogenous, equation 2 this then it includes all solutions of equation 2. So, let us see how we get this. Let y equal to $c_1 y_1(x)$ plus $c_2 y_2(x)$ be a general solution of equation 2 on an interval I where the coefficients $f(x)$ and $g(x)$ are continuous, and y be a any solution of equation 2 containing no arbitrary constants, then this y is obtained from 4 by assigning a suitable value to the constants. So, this general solution includes all solutions of the equation 2. So, this is what is conveyed by this theorem with this I would like to conclude my lecture.

Thank you very much for your attention.
