Lecture – 21
Solution of first order non – linear equation – III

Hello friends. Welcome to my third lecture on solution of first order non-linear equations. In previous 2 lectures we have discussed first order non-linear equations of type one 2 and 3. In this lecture we shall discuss the forth type of standard type of first order non-linear equations. And then we shall discuss the general method of solving such non-linear equations first of first order, which cannot be reduced to any those 4 standard forms. So, let us begin with first order non-linear equations of type 4.

So, in the in this category we consider those kind of equations which are of the form z equal to $p x$ plus $q y$ plus $f p q$ and as you remember p and q denotes the partial derivatives of z with respect to x and y .

(Refer Slide Time: 01:09)

Type IV : Equations of the type $z = p x + q y + f(p, q)$:

Let $z = p x + q y + f(p, q)$. (1)

Then equation (1) is analogous to Clairaut's ordinary differential equation

$$y = p x + f(p).$$

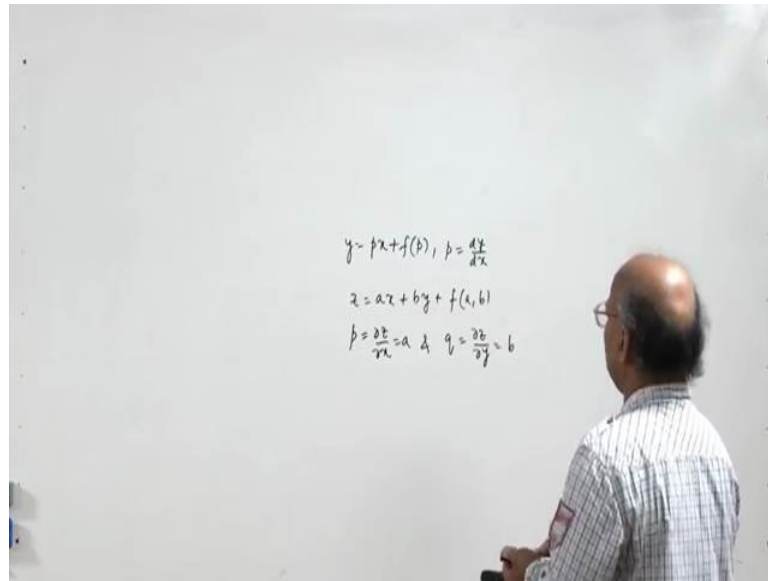

The complete integral of equation (1) is

$$z = a x + b y + f(a, b) \quad (2)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So, if z is $p x$ plus $q y$ plus $f p q$, then this equation you can see analogous to Clairaut's ordinary differential equation. The Clairaut's ordinary differential equation is y plus $p x$ plus $f p$, where p is $d z$ by dx . In the ordinary differential equation Clairaut's form is $p x$ plus $f p$, where p is $d y$ by $d x$.

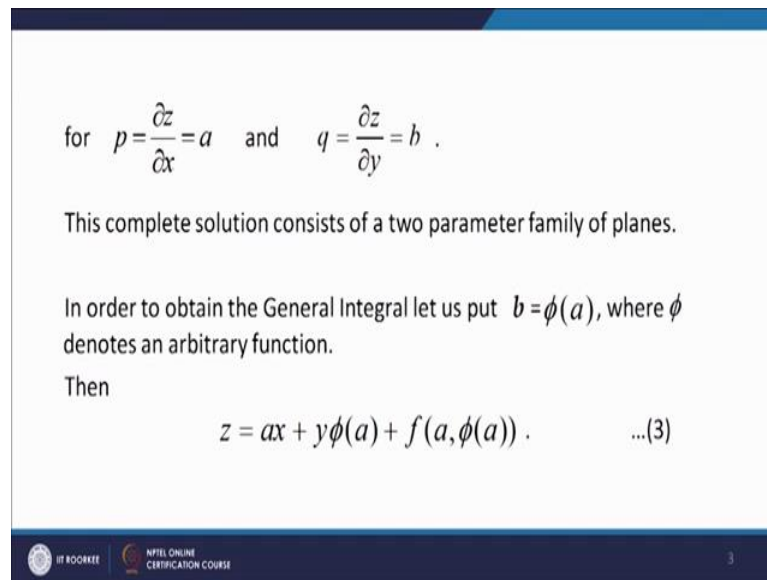

(Refer Slide Time: 01:40)

So, the partial differential equation $z = px + qy + f(p, q)$, is analogous to the Clairaut's ordinary differential equation $y = px + f(p)$. The complete integral of equation 1 is then given by $z = ax + by + f(a, b)$. Because we can see that, when $z = ax + by + f(a, b)$, then your partial derivative with respect to x which we have denoted by p , it will be equal to a and q , which is the partial derivative of z with respect to y , it will be equal to b and therefore, $z = ax + by + f(a, b)$. This is a solution of equation 1. Because when you put $z = ax + by + f(a, b)$ into 1, it is satisfied due to the fact that the value of p is a and the value of q is b .

So, this complete solution you can see $z = ax + by + f(a, b)$. This solution represents a plane and it is a 2-parameter family of planes. Because there are 2 parameters a and b . So, it is a 2-parameter family of planes. Now in order to obtain the general integral as we have earlier discussed.

(Refer Slide Time: 03:38)

for $p = \frac{\partial z}{\partial x} = a$ and $q = \frac{\partial z}{\partial y} = b$.

This complete solution consists of a two parameter family of planes.

In order to obtain the General Integral let us put $b = \phi(a)$, where ϕ denotes an arbitrary function.

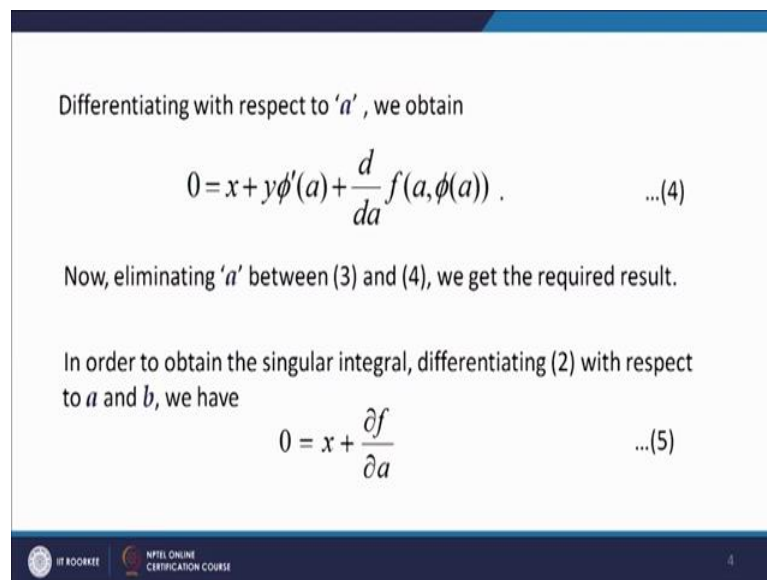

Then

$$z = ax + y\phi(a) + f(a, \phi(a)) . \quad \dots(3)$$

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE 3

Let us put b equal to phi a in this solution and where phi denotes an arbitrary function. Then z will be equal to a z equal to a x plus y into phi a plus y into phi a plus f a phi a.

(Refer Slide Time: 03:48)

Differentiating with respect to 'a', we obtain

$$0 = x + y\phi'(a) + \frac{d}{da} f(a, \phi(a)) . \quad \dots(4)$$

Now, eliminating 'a' between (3) and (4), we get the required result.

In order to obtain the singular integral, differentiating (2) with respect to a and b, we have

$$0 = x + \frac{\partial f}{\partial a} \quad \dots(5)$$

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE 4

We differentiate this equation with respect to a to get z d 0 equal to x plus y phi dash a plus d over d a of f a phi a. And then eliminate a between equation 3, this equation and the equation 4, to get the general integral.

Now, in order to obtain the singular integral, we differentiate equation 2. This one z equal to a x plus b y plus f a b which is the complete integral with respect v we differentiate this with respect to a.

(Refer Slide Time: 04:29)

and
$$0 = y + \frac{\partial f}{\partial b} . \quad (6)$$

Now eliminating a and b between the equations (2), (5) and (6), we reach the desired result.

Examples:

(1). $z = p x + q y + p q .$

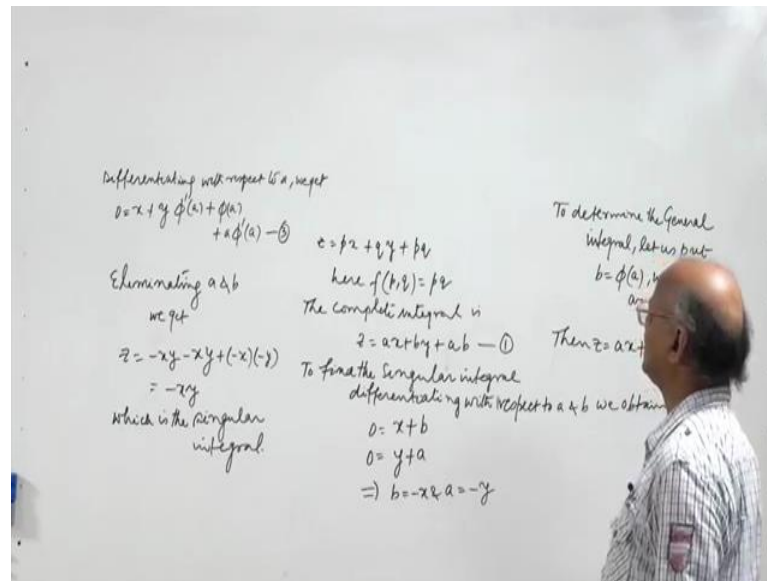

(2). $z = p x + q y + \sqrt{(1+p^2+q^2)} .$

IT ROOBBEE NPTEL ONLINE CERTIFICATION COURSE 5

So, we will get 0 equal to x plus d over delta over delta a of f a b, 0 equal to x plus delta f over delta a. And the second one will be when we differentiate with respect to b we will get 0 equal to y plus delta f over delta v. So, we have 3 equations now. Equation 2 which is the complete integral this one and then the equations 5 z 0 equal to x plus delta f over delta a; and 6 that is 0 equal to y plus delta f over delta v. So, we eliminate a and b between these 3 equations 2 reach the singular integral.

Let us see how we apply this method to some differential equations. Let us begin with the first example z equal to p x plus q y plus f p q.

(Refer Slide Time: 05:06)

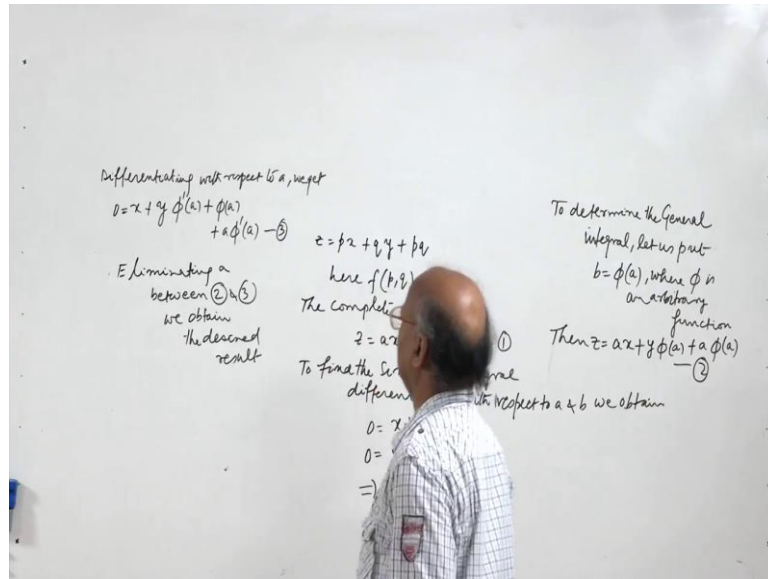

So, let us consider z equal to $p x$ plus $q y$, plus $f p q$. And we can see of the Clairauts form, z equal to $p x$ plus sorry here it is $p q$ not $f p q$. So, let us consider z equal to $p x$ plus $q y$ plus $p q$ is here, $f p q$ is equal to $p q$. So, it is a equation of type 4. Now let us. So, the complete integral is, z equal to $a x$ plus $b y$ plus $a b$. So, this is the complete integral to find the singular integral let us differentiate 1 with respect to a differentiating with respect to a and b . We obtain 0 equal to x plus b and when we differentiate with respect to v we will get 0 equal to x plus b , and when we differentiate with respect to b , we will get 0 plus y plus a . So, which imply x is equal to minus b , b equal to minus x .

Let us I will write like this, b equal to minus x and a equal to minus y . So, now, eliminating a and b between equation 1 and these 2 equations we have, eliminating a and b we obtain z equal to a is minus y . So, minus $x y$ b is minus x , so minus $x y$ plus minus x into minus y . So, we get minus $x y$. See this is the, which is the singular integral in this case. To determine the general integral, let us put b equal to ϕa where ϕ is an arbitrary function. So, then z will be equal to, $a x$ plus y into ϕa plus a into ϕa . Now we differentiate with respect to a .

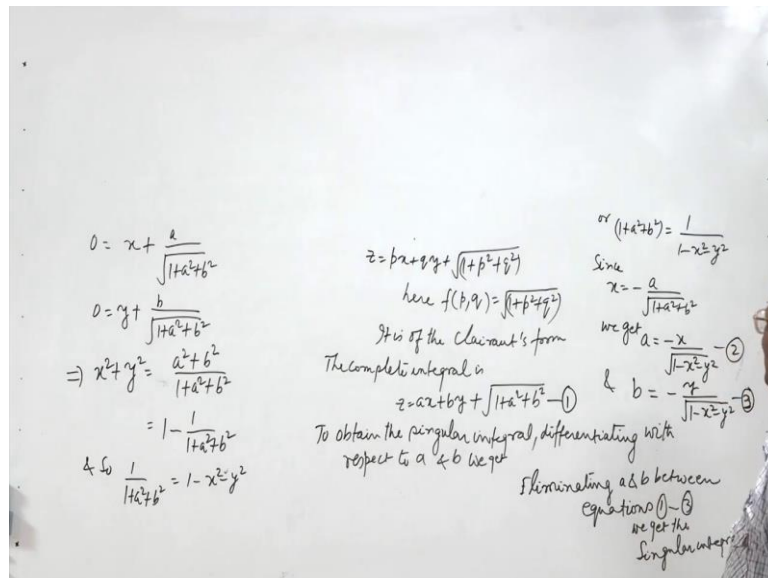

So, differentiating, we get 0 equal to x plus y times ϕ dash a , plus ϕa , into a ϕ dash a . Let me call it as equation number 2 and this as equation number 3. So, then we eliminate a between equations 2 and 3 to determine the general integral.

(Refer Slide Time: 09:50)

So, eliminating a between 2 and 3, we obtain the desired result. So, we will get the general integral. So, that is how we solve the problem given in example 1. Now let us take up the problem number 2. So, we have z equal to p x plus q y, plus under root 1 plus p square plus q square.

(Refer Slide Time: 10:26)

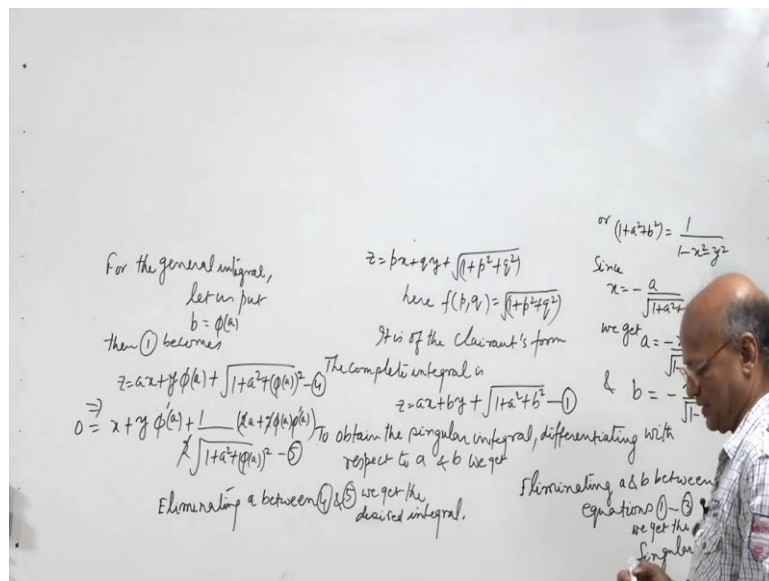

Now, we can see that here 1 plus p q is equal to under root 1 plus p square plus q square. So, it is of the Clairaut's form. So, this, the complete integral is therefore, a z equal to a x plus b y plus under root 1 plus a square plus b square. To determine the complete

integral to determine the; this is the complete detail to obtain the singular integral, we differentiate with respect to a and b. Differentiating we get 0 equal to x plus a upon under root 1 plus a square plus b square. And when we differentiate with respect to b we get 0 equal to y plus b upon under root 1 plus a square plus b square.

Now, from these 2 equations we get, x equal minus a upon under root 1 plus a square plus b square. And y equal to minus b upon under root a square plus 1 plus a square plus b square. So, x square plus y square is equal to a square plus b square divided by 1 plus a square plus b square, which can be written as 1 minus 1, upon 1, plus a square plus b square. And so 1 upon, 1 plus a square plus b square is equal to 1 minus x square minus y square, or we can say 1 plus a square plus b square is equal to 1 over 1 minus x square minus y square.

Now, x is equal to minus a upon under root 1 plus a square plus b square. So, x is equal to minus a upon under root 1 plus a square plus b square. We will get a as a equal to minus x into under root 1 plus a square plus b square. So, minus x times, So, a is equal to minus x into under root 1 plus a square, which is this equal to this and similarly b is equal to b is equal to minus y minus y upon under root 1 minus x square minus b square yeah. So, now, eliminating a and b between equation 1. And so eliminating a and b between equations 1 2 3, we get the singular integral. We get the singular integral and for general integral as we have discussed earlier.

(Refer Slide Time: 15:25)

So, for the general integral, let us put b equal to ϕa , then 1 becomes z equal to $a x$ plus $b \phi$ plus ϕa , plus under root 1 plus a square plus ϕa whole square. We differentiate this equation with respect to a , and get 0 equal to this implies 0 equal to x plus $y \phi$ dash a , plus 1 over 2 times under root 1 plus a square plus ϕa whole square. And then we have $2 a$ plus 2 times ϕa into ϕ dash a . This 2 can be cancelled. So, we have this equation. So, eliminating a , between this equation and this equation this. We call it as this as 4 and this as 5. So, eliminating a between 4 and 5 we get the desired integral.

This is how we solve these 2 equations. Now we go to the general method of solving first order non-linear equations which we call as the Charpit's method.

(Refer Slide Time: 17:37)

Charpit's Method:

Now, we shall consider the Charpit's Method of solving non-linear partial differential equations of the first order with two independent variables. This method should be applied when the given partial differential equation can not be reduced to any of the four standard forms because finding the complete integral by Charpit's method is generally more cumbersome.

Let

$$f(x, y, z, p, q) = 0, \quad \dots(1)$$

be the given partial differential equation.

IT 6000002 NPTEL ONLINE CERTIFICATION COURSE 6

So, here in this method, we consider non-linear partial differential equation of first order which cannot be reduced to the 4 standard forms, which we have already discussed. We will apply this method only in the cases where the first order non-linear partial differential equations cannot be reduced to the 4 standard form because to find the complete integral by applying the Charpit's method, it is rather more cumbersome.

So, we prefer to solve the partial differential equations which are of first order and non-linear by trying to reduce them to the 4 standard forms. If it is not possible to do that then we apply the Charpit's method. So, here what we do is let us consider first order non-linear partial differential equation, as a given by $f(x, y, z, p, q) = 0$. We know that

since there are 2 independent variables x and y and z is dependent on x and y . So, we can write the dz equal to $p dx + q dy$.

(Refer Slide Time: 18:38)

We have also

$$dz = p dx + q dy \quad (2)$$

The essence of Charpit's method consists in finding another relation

$$\phi(x, y, z, p, q) = 0 \quad (3)$$

such that when the values of p and q derived from it and the given equation are substituted in equation (2), it becomes integrable. The integral of (2) thus obtained satisfies equation (1) because the values of p and q obtained from it are no other than those previously derived from (1).

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

Now, in the Charpit's method we try to find relation between x , y , z and p , q . Say we can when from which and the given partial differential equation which when we when we obtain the values of p and q , and put them in the equation $dz = p dx + q dy$, if it is integrable, we get the complete integral of the given partial differential equation. So, in this method we will try to find a relation involving x , y , z , p , q equal to 0. And then saw which this equation 3 and the equation 1. The given partial differential equation be then solving to find the values of p and q , which when we put in $dz = p dx + q dy$, if it is integrable we get the complete integral of the given partial differential equation.

(Refer Slide Time: 19:44)

Let us assume that (3) is the relation of the required type.
Therefore, we may consider z, p, q expressed as functions of x and y so that when these values are substituted in $f = 0, \phi = 0$ they are satisfied identically. Therefore their derivatives with respect to x and y will vanish. Hence

$$\frac{\partial f}{\partial x} + \frac{\partial f}{\partial z} p + \frac{\partial f}{\partial p} \frac{\partial p}{\partial x} + \frac{\partial f}{\partial q} \frac{\partial q}{\partial x} = 0 ,$$
$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial z} p + \frac{\partial \phi}{\partial p} \frac{\partial p}{\partial x} + \frac{\partial \phi}{\partial q} \frac{\partial q}{\partial x} = 0 ,$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 8

So, let us assume that the 3 this equation, $z \phi z \phi x y z p q$ equal to 0 is the required relation, then $z p$ and q . So, p is Δz by Δx q is Δz by Δy , they are expressive they are functions of x and y . So, that when they are substituted in the equations f equal to 0, this equation f equal to 0, and ϕ equal to 0 they are satisfied identically.

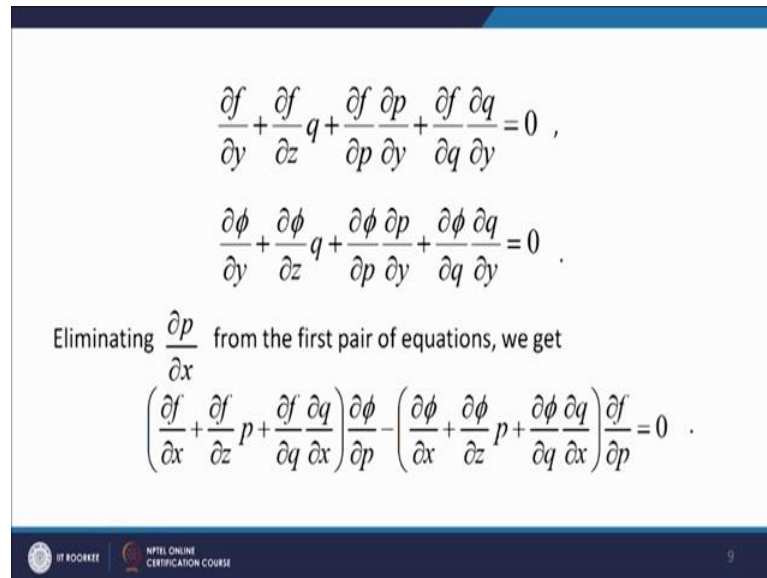

So, now, when we differentiate f equal to 0 with respect to x , what we get is Δf by Δx plus Δf by Δz into Δz , by Δx which is equal to p , plus Δf by Δp , Δp by Δx , Δf by Δq , Δq by Δx equal to 0. This is obtained by solving f equal to 0 with respect to x . Similarly, when we solve differentiate ϕ with respect to x , we will get $\Delta \phi$ by Δx plus $\Delta \phi$ by Δz into p , $\Delta \phi$ by Δp , Δp by Δx plus $\Delta \phi$ by Δq Δq by Δx is equal to 0.

(Refer Slide Time: 20:50)

$$\frac{\partial f}{\partial y} + \frac{\partial f}{\partial z} q + \frac{\partial f}{\partial p} \frac{\partial p}{\partial y} + \frac{\partial f}{\partial q} \frac{\partial q}{\partial y} = 0 ,$$

$$\frac{\partial \phi}{\partial y} + \frac{\partial \phi}{\partial z} q + \frac{\partial \phi}{\partial p} \frac{\partial p}{\partial y} + \frac{\partial \phi}{\partial q} \frac{\partial q}{\partial y} = 0 .$$

Eliminating $\frac{\partial p}{\partial x}$ from the first pair of equations, we get

$$\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial z} p + \frac{\partial f}{\partial q} \frac{\partial q}{\partial x} \right) \frac{\partial \phi}{\partial p} - \left(\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial z} p + \frac{\partial \phi}{\partial q} \frac{\partial q}{\partial x} \right) \frac{\partial f}{\partial p} = 0 .$$

And 2 similar equations are obtained from $f = 0$ and $\phi = 0$ by differentiating them with respect to y . And they are $\frac{\partial f}{\partial y} + \frac{\partial f}{\partial z} q + \frac{\partial f}{\partial p} \frac{\partial p}{\partial y} + \frac{\partial f}{\partial q} \frac{\partial q}{\partial y} = 0$. And $\frac{\partial \phi}{\partial y} + \frac{\partial \phi}{\partial z} q + \frac{\partial \phi}{\partial p} \frac{\partial p}{\partial y} + \frac{\partial \phi}{\partial q} \frac{\partial q}{\partial y} = 0$. And $\frac{\partial \phi}{\partial y} + \frac{\partial \phi}{\partial z} q + \frac{\partial \phi}{\partial p} \frac{\partial p}{\partial y} + \frac{\partial \phi}{\partial q} \frac{\partial q}{\partial y} = 0$.

Now, what we do is, let us eliminate $\frac{\partial p}{\partial x}$, from the first pair there are 4 equations, so from the first 2 equations first pair of equations. Let us eliminate this derivative. Derivate of p with respect to x , so $\frac{\partial p}{\partial x}$ let us eliminate from these 2 equations, and which is not difficult because it is a linear equation. So, this will give you $\frac{\partial f}{\partial x} + \frac{\partial f}{\partial z} p + \frac{\partial f}{\partial q} \frac{\partial q}{\partial x}$ into $\frac{\partial \phi}{\partial p}$, $\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial z} p + \frac{\partial \phi}{\partial q} \frac{\partial q}{\partial x}$ into $\frac{\partial f}{\partial p}$. So, this we can obtain this equation is very simple. And then what we do is we can write it as we can write it in the form.

(Refer Slide Time: 21:54)

Therefore

$$\left(\frac{\partial f}{\partial x} \frac{\partial \phi}{\partial p} - \frac{\partial \phi}{\partial x} \frac{\partial f}{\partial p}\right) + p \left(\frac{\partial f}{\partial z} \frac{\partial \phi}{\partial p} - \frac{\partial \phi}{\partial z} \frac{\partial f}{\partial p}\right) + \frac{\partial q}{\partial x} \left(\frac{\partial f}{\partial q} \frac{\partial \phi}{\partial p} - \frac{\partial \phi}{\partial q} \frac{\partial f}{\partial p}\right) = 0 \dots (4)$$

Similarly eliminating $\frac{\partial q}{\partial y}$ between the last pair of equations, we get

$$\left(\frac{\partial f}{\partial y} \frac{\partial \phi}{\partial q} - \frac{\partial \phi}{\partial y} \frac{\partial f}{\partial q}\right) + q \left(\frac{\partial f}{\partial z} \frac{\partial \phi}{\partial q} - \frac{\partial \phi}{\partial z} \frac{\partial f}{\partial q}\right) + \frac{\partial p}{\partial y} \left(\frac{\partial f}{\partial p} \frac{\partial \phi}{\partial q} - \frac{\partial \phi}{\partial p} \frac{\partial f}{\partial q}\right) = 0 \dots (5)$$

The we collect the terms which contain p and the terms, which contain delta q by delta x, and this constant this term, which is free from p and delta q by delta x.

So, we can write those that this equation. We can write this equation in the form this one. So, we similarly let us eliminate delta q over delta y, to this delta q over delta y in let us eliminate from this pair of equations. So, for that you need to multiply this equation by delta phi over delta q, and this 4th equation by delta f over delta q and then subtract. So, delta q over delta y term will vanish, so eliminating delta q over delta y between the last pair of equations. We shall have this one, delta f over delta y delta phi by delta q minus delta phi by delta y, delta f by delta q plus q, times this, plus delta v over delta y times this equal to 0.

Now, let us notice one thing, delta q is delta z by delta y. So, delta q by delta x is delta square z by delta x delta y, and p is delta z by delta x. So, delta p by delta y is delta square z, by delta x delta y. And assuming that the second order partial derivatives are continuous, delta square z by delta x delta y is same as delta square z by delta y delta x. We know is we know this result. So, delta q over delta x and delta p over delta y are same. And this they are coefficient you can see is also same, except for the negative sign. This is negative of this. So, when we add these 2 equations, the last term this term here and this term here they will cancel out.

(Refer Slide Time: 23:42)

Now,
$$\frac{\partial q}{\partial x} = \frac{\partial^2 z}{\partial x \partial y} = \frac{\partial p}{\partial y} .$$

Therefore adding the equations (4) and (5) and rearranging the terms, we get

$$\left(\frac{\partial f}{\partial x} + p \frac{\partial f}{\partial z}\right) \frac{\partial \phi}{\partial p} + \left(\frac{\partial f}{\partial y} + q \frac{\partial f}{\partial z}\right) \frac{\partial \phi}{\partial q} + \left(-p \frac{\partial f}{\partial p} - q \frac{\partial f}{\partial q}\right) \frac{\partial \phi}{\partial z} + \left(-\frac{\partial f}{\partial p}\right) \frac{\partial \phi}{\partial x} + \left(-\frac{\partial f}{\partial q}\right) \frac{\partial \phi}{\partial y} = 0 ,$$

since the terms involving $\frac{\partial p}{\partial y}$ and $\frac{\partial q}{\partial x}$ cancel.

So, now let us notice that delta q over delta x is equal to delta p over delta y. So, we have this one, delta q over delta x equal to delta square z by delta x, delta y and which is equal to delta p over delta y, because we are assuming that second order partial derivatives are continuous. So, when we add the equations 4 and 5, as we have discussed just now. This is negative of this quantity. And this delta q over delta x and delta p over delta y are same.

So, when we add the equations 4 and 5, and rearrange the terms, what happens is this term and this term they cancel out. And what we get is this. So, delta f over delta x plus p times delta f over delta z into delta phi over p, plus delta f over delta y plus q times delta f over delta z, delta phi by delta q plus, minus p delta f f by delta p, minus q delta f by delta q, delta phi by delta z plus minus delta f by delta p, into delta phi by delta x minus delta f, by delta q into delta phi over delta y equal to 0, as since the terms involving are the partial derivative of p with respect to y, and partial derivative of q with respect to x cancel.

(Refer Slide Time: 24:55)

The equation (6) is a partial differential equation of the first order in ϕ .
 Its integrals are the integrals of the auxiliary equations

$$\frac{dp}{\frac{\partial f}{\partial x} + p} = \frac{dq}{\frac{\partial f}{\partial y} + q} = \frac{dz}{-p \frac{\partial f}{\partial p} - q \frac{\partial f}{\partial q}} = \frac{dx}{-\frac{\partial f}{\partial p}} = \frac{dy}{-\frac{\partial f}{\partial q}} = \frac{d\phi}{0} \dots(7)$$

Any of the integrals of (7) will satisfy (6). We should take the simplest relation involving at least one of p and q for $\phi = 0$, so that the values of p and q may be obtained easily.

 IIT ROORKEE
  NPTL ONLINE CERTIFICATION COURSE
 12

Now, the equation 6 is a partial differential equation of the first order in ϕ , now let us see. This is a partial differential equation of the first order in ϕ . Because ϕ is a function of x, y, z, p and q , and you can see here we have in the first term partial derivative of ϕ with respect to p , partial derivative of ϕ with respect to q , partial derivative of ϕ with respect to z , partial derivative of ϕ with respect to x , partial derivative of ϕ with respect to y which are of first order. So, it is a first order linear differential equation in ϕ . And therefore, its integrals are the integrals of the auxiliary equations, as we have discussed in the case of Lagrange's linear equation in p and q it is same it is of the same.

So, we have dp over this quantity and dq over this dz over this quantity, and dx over minus $\frac{\partial f}{\partial p}$ dy over minus $\frac{\partial f}{\partial q}$, equal to $d\phi$ over 0. We are actually solving this equation like we have solved the Lagrange's linear equation in p and q . So, it is a linear equation in the derivatives of ϕ with respect to p, q, z, x and y . So, we solve this auxiliary system of equations. Now any of the integrals of this equation 7 will satisfy 6, and therefore, we take the simplest relation involving at least one of p and q , for $\phi = 0$, so that the values of p and q may be obtained easily. Once the values of p and q are obtained easily, we can take the help of the given equation $f(x, y, z, p, q) = 0$, and determine the value of the other q or p . And once p and q are known, we can use $dz = p dx + q dy$ and determine the complete integral.

So, we shall be able to determine the complete integral by writing the auxiliary system of equations. And this auxiliary system of equations will then, we will find the shortest simplest relation involving at least one of p and q for ϕ equal to 0. And then we may use these value, this relation for p with in p and q and determine the values of p and q . So, when we put them in the equation dz equal to $p dx$ plus $q dy$, and integrate we shall obtain the complete integral which will be the complete integral of the given partial differential equation. And the similar and a general integral are then obtained in the usual manner. So, with that I would like to conclude my lecture.

Thank you for your attention.
