Lecture – 24
Laplace Transforms of some standard functions

So, in the last class, we have seen what are Laplace transforms, and how to find Laplace transform of some simple functions like 1 t or e k power a t.

(Refer Slide Time: 00:35)

The image shows a handwritten derivation of the Laplace transform of t^n . On the left side, the derivation starts with $L\{t^n\} = \int_0^{\infty} t^n e^{-pt} dt$. A substitution $pt = z$ is used, leading to $t = \frac{z}{p}$ and $dt = \frac{dz}{p}$. The integral becomes $\int_0^{\infty} \left(\frac{z}{p}\right)^n e^{-z} \frac{dz}{p}$, which simplifies to $\frac{1}{p^{n+1}} \int_0^{\infty} z^n e^{-z} dz$. This is recognized as $\frac{1}{p^{n+1}} \Gamma(n+1)$. On the right side, the general definition of the Laplace transform is given as $L\{f(t)\} = \int_0^{\infty} f(t) e^{-pt} dt = F(p)$.

So, what is Laplace transform any function f t? Laplace transform any function f t is nothing, but 0 to infinity f t e k power minus p t dt, and we are calling it F p, function of p. So, also we have seen that Laplace transform satisfy linearity property. So, now, in this lecture, we will find Laplace transform of some standard functions. So, first what is Laplace transform of t k power n? So, Laplace transform of t k power n.

(Refer Slide Time: 01:14)

Laplace transforms of some standard functions

$$L[t^n] = \frac{\Gamma(n+1)}{p^{n+1}}, \quad p > 0, n > -1$$

Since for positive integer n , $\Gamma(n+1) = n!$, therefore

$$L[t^n] = \frac{n!}{p^{n+1}}, \quad p > 0, n = 1, 2, \dots$$

Find?

$$L[3t^{3/2} + 5t - 4e^{2t}] \qquad L^{-1}\left(\frac{p^3 + 2}{p^5}\right)$$

iiit ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

Let us try to find its Laplace or t^k power n . So, using the definition of Laplace transform, Laplace t^k power n nothing, but 0 to infinity, t^k power n $e^{-k \text{ power } n} dt$. Now let $p t$ is equals to some variable, say z . So, it will be nothing, but 0 to infinity z by p whole power n $e^{-k \text{ power } n} z$, and dt is nothing, but $d z$ upon p . So, it is nothing, but 1 upon p t^k power n plus 1 integral 0 to infinity z^k power n $e^{-k \text{ power } n} z$ into $d z$, and this function is nothing, but gamma function. So, it is 1 upon p n plus 1 gamma of n plus 1 . Now, as gamma n plus 1 is factorial n , when n is a positive integer. Therefore, Laplace transform of t^k power n will be factorial n upon p k power n plus 1 , when n is a positive integer.

(Refer Slide Time: 02:53)

$$\begin{aligned}
 & \mathcal{L}\{3t^{3/2} + 5t - 4e^{2t}\} \\
 &= 3\mathcal{L}\{t^{3/2}\} + 5\mathcal{L}\{t\} - 4\mathcal{L}\{e^{2t}\} \\
 &= 3 \frac{\Gamma(5/2)}{p^{5/2}} + 5 \frac{1}{p^2} - 4 \frac{1}{p-2} \\
 &= 3 \frac{\frac{3}{2} \Gamma(3/2)}{p^{5/2}} + \frac{5}{p^2} - \frac{4}{p-2} \\
 &= \frac{3 \cdot \frac{3}{2} \cdot \frac{1}{2} \Gamma(1/2)}{p^{5/2}} + \frac{5}{p^2} - \frac{4}{p-2} \\
 &= \frac{9 \sqrt{\pi}}{4 p^{5/2}} + \frac{5}{p^2} - \frac{4}{p-2}
 \end{aligned}$$

$$\begin{aligned}
 & \mathcal{L}\{f(t)\} \\
 &= \int_0^{\infty} f(t) e^{-pt} dt = F(p) \\
 & \Gamma(n+1) = n \Gamma(n) \\
 & \Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}
 \end{aligned}$$

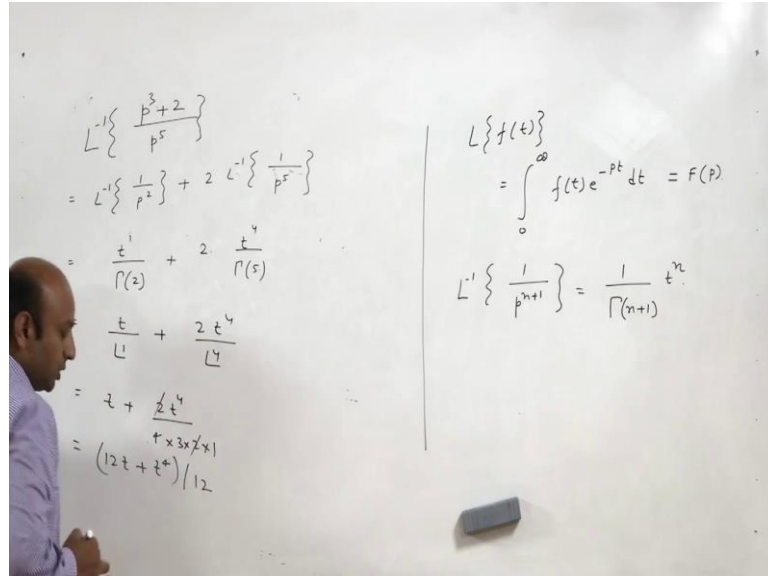

Now, let us try to solve the two problems given below, Laplace transform of $3t^{3/2} + 5t - 4e^{2t}$. Now again by the linearity property of Laplace transform, this is nothing but 3 times Laplace of $t^{3/2}$ plus 5 Laplace of t minus 4 Laplace of e^{2t} . So, this is 3 into. Now Laplace of t^k power n as in the first expression we are having, it is $\frac{\Gamma(n+1)}{p^{n+1}}$.

So, here n is not a integer, here n is positive integer. So, we have to use the first definition of t^k power n , it is $\frac{\Gamma(n+1)}{p^{n+1}}$. So, it is $\frac{\Gamma(n+1)}{p^{n+1}}$. Here n is $3/2$, so it is $\frac{\Gamma(5/2)}{p^{5/2}}$. Laplace of t we have already seen that it is $\frac{1}{p^2}$, also we can obtain here from here, also when we put n equal to 1 in the, sorry in the second expression. So, it is $\frac{1}{p^2}$ minus 4 into Laplace of e^{2t} is $\frac{1}{p-2}$. So, it will be nothing, but $\frac{9\sqrt{\pi}}{4p^{5/2}} + \frac{5}{p^2} - \frac{4}{p-2}$.

So, now $\Gamma(n+1)$, we already know it is $n \Gamma(n)$ nothing, but $n \Gamma(n)$, and Γ is half under root pi, this we already know, so 3 into. Now $\Gamma(5/2)$, so here it is $3/2 \Gamma(3/2)$ upon $p^{5/2}$ plus 5 upon p^2 minus 4 upon $p-2$ is equal to $3 \frac{\Gamma(3/2)}{p^{5/2}}$. Again we will use a same expression; instead of n we have $1/2$, because $1/2 + 1$ is $3/2$. So, $1/2 \Gamma(1/2)$ upon $p^{3/2}$ plus 5 upon p^2 minus 4 upon $p-2$. So, $1/2 \Gamma(1/2)$ upon $p^{3/2}$ plus 5 upon p^2 minus 4 upon $p-2$. So, it is nothing, but $\frac{9\sqrt{\pi}}{4p^{5/2}} + \frac{5}{p^2} - \frac{4}{p-2}$.

gamma half is under root pi. So, it is under root pi upon p k power to 5 by 2 plus 5 upon p square minus 4 upon p minus 2. So, this is the Laplace transform of this function.

(Refer Slide Time: 06:36)

Now, how to find Laplace inverse of this expression $p^3 + 2$ upon p^5 ? So, Laplace inverse of $p^3 + 2$ upon p^5 . So, it is Laplace inverse of 1 by $p^2 + 2$ into Laplace inverse of 1 by p^3 . Now recall the definition, Laplace transform t^k power n is given as $\gamma(n + 1)$ upon $p^{n + 1}$. So, what will be the Laplace inverse of 1 upon $p^{n + 1}$ from here? It is nothing, but $\gamma(n + 1)$ is a constant quantity. So, it will put, it will go to the right hand side. So, it will be nothing, but 1 upon $\gamma(n + 1)$ into t^k power n by that definition.

So, Laplace inverse of 1 by p^2 , so 1 by p^2 means n is 1 , when n is 1 , so it is nothing, but t^k power 1 upon $\gamma(2)$ into. Now for this expression n is 4 , when n is 4 . So, it will be nothing, but t^k power 4 upon $\gamma(5)$, it is t . Now $\gamma(n + 1)$ is factorial n , when n is the positive integer. So, it is $\gamma(2)$ to this factorial $1 + 2$ t^k power 4 upon factorial 4 . So, it is $t + 2 t^k$ power 4 upon $4 \times 3 \times 2 \times 1$. So, 2×2 cancels out. So, it nothing, but $12 t + t^k$ power 4 divided by 12 . So, this will be the value of Laplace inverse of this function.

(Refer Slide Time: 08:59)

$$\sin at = \frac{e^{iat} - e^{-iat}}{2i}$$

$$L\{\sin at\} = \frac{1}{2i} L\{e^{iat}\} - \frac{1}{2i} L\{e^{-iat}\}$$

$$= \frac{1}{2i} \left(\frac{1}{p-ia} \right) - \frac{1}{2i} \left(\frac{1}{p+ia} \right)$$

$$= \frac{1}{2i} \left(\frac{2ia}{p^2+a^2} \right)$$

$$= \frac{a}{p^2+a^2}$$

$$L\{f(t)\} = \int_0^{\infty} f(t)e^{-pt} dt = F(p)$$

$$L^{-1}\left\{ \frac{1}{p^{n+1}} \right\} = \frac{t^n}{n!}$$

$$L^{-1}\left\{ \frac{1}{p^2+a^2} \right\} = \frac{1}{a} \sin at$$

Now, how to find Laplace of sin a t? So, now, we will see how to find Laplace of sin a t. So, sin a t, as we already know is nothing, but e k power iota a t minus e k power minus iota a t upon 2 iota. This is sin a t. Now Laplace of sin a t, using linearity property of Laplace transform will be nothing, but 1 upon 2 iota, Laplace of e k power iota a t minus 1 upon 2 iota Laplace of e k power minus iota a t. So, it is nothing, but 1 upon 2 iota. As we already know let Laplace of e k power a t is 1 upon p minus a. Here instead of a, we have iota a. So, we will replace a by iota a 1 upon p minus iota a minus 1 upon 2 iota.

Again here instead of a, we are having minus iota a. So, we will replace a by minus iota a. So, we will get 1 upon p plus iota a. So, we will take 1 upon 2 iota a is common. So, and the numerator will get 2 a upon p square minus a square 2 iota a, sorry. So, 2 iota will cancel out. So, it is nothing, but it is p square plus a square when we multiply this 2. So, it is a upon p square plus a square. So, this is Laplace transform of sin a t it is a upon p square plus a square.

Now, so therefore, if you want to find out Laplace inverse of this function, this F p, this will be nothing, but sin at. So, what will be Laplace inverse of 1 upon p square plus a square, it will be nothing, but 1 by a sin a t. Now Laplace transform of cos a t, in the similar way we can find out Laplace transform of cos a t also. So, what is called cos a t in terms of t?

(Refer Slide Time: 11:27)

$$\begin{aligned} \cos at &= \frac{e^{iat} + e^{-iat}}{2} \\ \mathcal{L}\{\cos at\} &= \frac{1}{2} \mathcal{L}\{e^{iat}\} + \frac{1}{2} \mathcal{L}\{e^{-iat}\} \\ &= \frac{1}{2} \left(\frac{1}{p-ia} \right) + \frac{1}{2} \left(\frac{1}{p+ia} \right) \\ &= \frac{1}{2} \left(\frac{2p}{p^2+a^2} \right) \end{aligned}$$

$$\begin{aligned} \mathcal{L}\{f(t)\} &= \int_0^{\infty} f(t)e^{-pt} dt = F(p) \\ \mathcal{L}^{-1}\left\{ \frac{1}{p^{n+1}} \right\} &= \frac{1}{\Gamma(n+1)} t^n \\ \mathcal{L}^{-1}\left\{ \frac{1}{p^2+a^2} \right\} &= \frac{1}{a} \sin at \end{aligned}$$

So, $\cos at$ will be nothing, but $\frac{e^{iat} + e^{-iat}}{2}$, this we already know. So, to find Laplace transform of $\cos at$, again we will apply linearity property of Laplace transform, Laplace transforms of $\cos at$ will be nothing, but $\frac{1}{2}$ Laplace transform of e^{iat} plus $\frac{1}{2}$ Laplace transform of e^{-iat} .

So, this is nothing, but $\frac{1}{2}$ Laplace transform of e^{iat} is $\frac{1}{p-ia}$. here instead of a we have ia it is $\frac{1}{p-ia}$ plus $\frac{1}{2}$ $\frac{1}{p+ia}$. So, when we simplify it, so we will get $\frac{1}{2}$ into $2p$ upon p^2+a^2 cancel out. So, Laplace transforms of $\cos at$ is nothing, but $\frac{p}{p^2+a^2}$. Similarly Laplace inverse of this $F(p)$, $\frac{p}{p^2+a^2}$ is nothing, but $\cos at$. Now what is Laplace transform of $\sin at$. Now we will try to find out this expression, to prove this expression in fact, so what is $\cos at$, sorry $\sin at$.

(Refer Slide Time: 13:05)

The image shows handwritten mathematical derivations on a whiteboard. On the left side, the definition of the hyperbolic sine function is given as $\sinh at = \frac{e^{at} - e^{-at}}{2}$. Below this, the Laplace transform of $\sinh at$ is derived using the linearity property: $L\{\sinh at\} = \frac{1}{2} L\{e^{at}\} - \frac{1}{2} L\{e^{-at}\}$. This is then simplified to $\frac{1}{2} \left(\frac{1}{p-a} \right) - \frac{1}{2} \left(\frac{1}{p+a} \right)$, which further simplifies to $\frac{1}{2} \left(\frac{p+a - p+a}{p^2 - a^2} \right)$, resulting in the final expression $\frac{a}{p^2 - a^2}$. On the right side, the definition of the Laplace transform is given as $L\{f(t)\} = \int_0^{\infty} f(t)e^{-pt} dt = F(p)$. Below this, two inverse Laplace transform formulas are listed: $L^{-1}\left\{\frac{1}{p^{n+1}}\right\} = \frac{1}{\Gamma(n+1)} t^n$ and $L^{-1}\left\{\frac{1}{p^2 + a^2}\right\} = \frac{1}{a} \sin at$.

Sin hyperbolic $a t$ is nothing but $e^{k \text{ power } a t}$ minus $e^{k \text{ power } -a t}$ upon 2. This we already know. So, how to find Laplace transform of sin hyperbolic $a t$? Again we will use linearity property of Laplace transforms. So, Laplace transform of sin hyperbolic $a t$ will be nothing, but $\frac{1}{2}$ Laplace transform of $e^{k \text{ power } a t}$ minus $\frac{1}{2}$ Laplace form of $e^{k \text{ power } -a t}$. So, it is $\frac{1}{2}$ Laplace transform of $e^{k \text{ power } a t}$ is $\frac{1}{p - a}$ minus $\frac{1}{2} \frac{1}{p + a}$. So, when we simplify this. So, we will get $\frac{1}{2} \left(\frac{p+a - p+a}{p^2 - a^2} \right)$. This p cancels out. So, it is nothing, but $\frac{a}{p^2 - a^2}$.

So, this would be the Laplace of sin hyperbolic $a t$. Similarly, if you want to find out Laplace inverse of this expression this $F(p)$, so it will be nothing but sin hyperbolic $a t$. Now what is Laplace transform of cos hyperbolic $a t$. in the similar way, on the same lines, we can obtain the second expression this expression for cos hyperbolic $a t$.

(Refer Slide Time: 14:51)

$$\cosh at = \frac{e^{at} + e^{-at}}{2}$$

$$\mathcal{L}\{\cosh at\} = \frac{1}{2} \mathcal{L}\{e^{at}\} + \frac{1}{2} \mathcal{L}\{e^{-at}\}$$

$$= \frac{1}{2} \left(\frac{1}{p-a} \right) + \frac{1}{2} \left(\frac{1}{p+a} \right)$$

$$= \frac{1}{2} \left(\frac{2p}{p^2 - a^2} \right)$$

$$\mathcal{L}\{f(t)\} = \int_0^{\infty} f(t) e^{-pt} dt = F(p)$$

$$\mathcal{L}^{-1}\left\{ \frac{1}{p^{n+1}} \right\} = \frac{t^n}{\Gamma(n+1)}$$

$$\mathcal{L}^{-1}\left\{ \frac{1}{p^2 + a^2} \right\} = \frac{1}{a} \sin at$$

So, what is cos hyperbolic a t? Cos hyperbolic a t is nothing, but e k power a t plus e k power minus a t upon 2, this we already know. Now Laplace transform of cos hyperbolic a t, will be 1 by 2, Laplace transform of e k power a t plus 1 by 2, Laplace transform of e k power minus a t. So, it is nothing, but 1 by 2, 1 upon p minus a Laplace of e k power a t we already know, it is 1 upon p minus a plus 1 by 2, it is 1 upon p plus a. So, it is 1 by 2, numerator we get 2 p upon p square minus a square, 2 2 cancels out. So, this will be the Laplace of cos hyperbolic a t. Now Laplace inverse of p upon p square minus a square is similarly cos hyperbolic a t, because this Laplace of f t is p f, then Laplace inverse of F p will be nothing, but f t, that we already know. So, this we already seen, Laplace inverse of these 3 expressions we already discussed.

(Refer Slide Time: 16:23)

The image shows handwritten mathematical work on a whiteboard. On the left side, the Laplace transform of $\cos(2t-3)$ is derived using the angle addition formula $\cos(2t-3) = \cos 2t \cos 3 + \sin 2t \sin 3$. The transform is then calculated as $(\cos 3) \frac{p}{p^2+4} + (\sin 3) \frac{2}{p^2+4}$, which simplifies to $\frac{p \cos 3 + 2 \sin 3}{p^2+4}$. On the right side, the general Laplace transform formula $L\{f(t)\} = \int_0^{\infty} f(t)e^{-pt} dt = F(p)$ is shown. Below it, the transform of t^n is given as $L\left\{\frac{1}{p^{n+1}}\right\} = \frac{1}{\Gamma(n+1)} t^n$, and the inverse transform of $\frac{1}{p^2+a^2}$ is given as $L^{-1}\left\{\frac{1}{p^2+a^2}\right\} = \frac{1}{a} \sin at$.

Now, how to find Laplace of this two function, this two simple function, let us see how to find Laplace of these functions Laplace of $\cos 2t$ minus 3. So, we know the Laplace of Laplace transformation of $\cos at$, Laplace transform of $\cos at$ is, p upon p square plus a square, but how to find Laplace transform of $\cos 2t$ minus 3; that is at plus b types how to find out the Laplace of this. So, it is $\cos a$ minus b . So, $\cos a$ minus b is nothing, but $\cos a \cos b$ plus $\sin a \sin b$.

Now, $\cos 3$ and $\sin 3$ are the constants free from t . So, can be taken out, because of the linearity property of Laplace transforms, so it is nothing, but $\cos 3$, Laplace transforms of $\cos 2t$ plus $\sin 3$ Laplace transform of $\sin 2t$. So, this is nothing, but $\cos 3$, and Laplace transform of $\cos 2t$ is, p upon p square plus 4 and plus $\sin 3$ Laplace transform of $\sin 2t$ is 2 upon p square plus 4, p square plus a square a is 2. So, this is nothing, but p into $\cos 3$ plus 2 into $\sin 3$ upon p square plus 4. So, this will be the Laplace transformation of $\cos 2t$ minus 3.

(Refer Slide Time: 18:07)

Find the Laplace transforms of the following?

$$L[\cos(2t - 3)]$$

$$L[\sin 3t \cos^2 t]$$

Now, the second problem, and now the next problem Laplace transform of $\sin 3t$ into \cos square t . So, Laplace transform of $\sin 3t$ into \cos square t .

(Refer Slide Time: 18:20)

$$L\{\sin 3t \cos^2 t\}$$

$$= L\left\{\sin 3t \left(\frac{1 + \cos 2t}{2}\right)\right\}$$

$$= L\left\{\frac{\sin 3t}{2} + \frac{\sin 3t \cos 2t}{2}\right\}$$

$$= \frac{1}{2} L\{\sin 3t\} + \frac{1}{2} L\{\sin 3t \cos 2t\}$$

$$= \frac{1}{2} \left(\frac{3}{p^2+3^2}\right) + \frac{1}{4} L\{2 \sin 3t \cos 2t\}$$

$$= \frac{3}{2(p^2+9)} + \frac{1}{4} L\{\sin 5t + \sin t\}$$

$$= \frac{3}{2(p^2+9)} + \frac{1}{4} \left(\frac{5}{p^2+5^2} + \frac{1}{p^2+1^2}\right)$$

$$L\{f(t)\} = \int_0^{\infty} f(t) e^{-pt} dt = F(p)$$

$$L^{-1}\left\{\frac{1}{p^{n+1}}\right\} = \frac{1}{\Gamma(n+1)} t^n$$

$$L^{-1}\left\{\frac{1}{p^2+a^2}\right\} = \frac{1}{a} \sin at$$

Now, we know how to find Laplace transform of $\sin 3t$, but we do not know how to find out Laplace transform of product of 2 functions, when both involves t . So, first we try to break this function. Now $\sin 3t$, what is \cos square t ? So, \cos square t can be written as $1 + \cos 2t$ by 2. Now this is nothing, but Laplace transform of $\sin 3t$ upon $2 + \sin 3t$

into $\cos 2t$ upon 2. This can be written as $\frac{1}{2}$ Laplace transform of $\sin 3t$ plus $\frac{1}{2}$ Laplace transform of $\sin 3t$ into $\cos 2t$.

So, Laplace of transform of $\sin 3t$ we already know, this is $\frac{3}{p^2 + 9}$ plus, but again we have a problem here, how to find Laplace transform of this. So, we multiply and divide by 2 in this expression. Now $2 \sin a \cos b$, we know that it is equal to $\sin(a+b) + \sin(a-b)$. So, it is $\frac{3}{2} \frac{2 \sin 3t \cos 2t}{p^2 + 9}$ plus $\frac{1}{4}$ Laplace of, it is $\sin 5t + \sin t$ plus this $\frac{3}{2} \frac{2 \sin 3t \cos 2t}{p^2 + 9}$.

So, now we can find out the Laplace of this expression. So, this is $\frac{3}{2} \frac{2 \sin 3t \cos 2t}{p^2 + 9}$ plus $\frac{1}{4}$ Laplace of $\sin 5t + \sin t$ is $\frac{1}{p^2 + 25} + \frac{1}{p^2 + 1}$. So, this will be the Laplace transform of this function $\sin 3t$ into $\cos^2 t$. So, now how to find Laplace inverse of this simple $F(p)$, the simple function? So, Laplace inverse of, it is $\frac{p-3}{p^2 + 4}$.

(Refer Slide Time: 21:23)

Find?

$$L^{-1} \left[\frac{p-3}{p^2+4} \right]$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

(Refer Slide Time: 21:25)

$$L^{-1}\left\{\frac{p-3}{p^2+4}\right\}$$

$$= L^{-1}\left\{\frac{p}{p^2+4} - \frac{3}{p^2+4}\right\}$$

$$= L^{-1}\left\{\frac{p}{p^2+4}\right\} - 3 L^{-1}\left\{\frac{1}{p^2+4}\right\}$$

$$\cos 2t - \frac{3}{2} \sin 2t$$

$$L\{f(t)\} = \int_0^{\infty} f(t)e^{-pt} dt = F(p)$$

$$L^{-1}\left\{\frac{1}{p^{n+1}}\right\} = \frac{1}{n!} t^n$$

$$L^{-1}\left\{\frac{1}{p^2+a^2}\right\} = \frac{1}{a} \sin at$$

So, this is simple to find out, you just split this into 2 parts p upon p square plus 4 minus 3 upon p square plus 4. Now, by the linearity property of inverse Laplace transforms, it is this into p upon p square plus 4 minus 3 times Laplace inverse of 1 upon p square plus 4. So, this Laplace inverse we already know. This Laplace inverse of this expression is $\cos 2t$, because it is $4 = 2^2$. So, it is $\cos 2t$, because Laplace of $\cos 2t$ is p upon p square plus 2^2 ; that is p upon p square plus 4. Now it is minus. Now Laplace inverse of 1 upon p square plus a square is $\frac{1}{a} \sin at$. So, here a is 2. So, it is $\frac{1}{2} \sin 2t$. So, this will be the Laplace inverse of this $F(p)$.

(Refer Slide Time: 22:57)

Find $L^{-1}\left[\frac{p+2}{(p-1)(p^2+4)}\right]$?

Solution: $F(p) = \frac{p+2}{(p-1)(p^2+4)} = \frac{3}{5(p-1)} + \frac{-3p+2}{5(p^2+4)}$

Hence,

$$f(t) = \frac{3}{5}e^t - \frac{3}{5}\cos 2t + \frac{1}{5}\sin 2t$$

NPTEL ONLINE CERTIFICATION COURSE

Now, how to find Laplace inverse of this problem? Now here $F(p)$ is what? $F(p)$ is p plus 2 upon p minus 1 into p square plus 4.

(Refer Slide Time: 23:02)

The image shows handwritten mathematical work on a whiteboard. On the left side, the function $F(p) = \frac{p+2}{(p-1)(p^2+4)}$ is decomposed into partial fractions: $\frac{A}{p-1} + \frac{Bp+C}{p^2+4}$. The equation $p+2 = A(p^2+4) + (Bp+C)(p-1)$ is used to find the coefficients, resulting in $A = \frac{3}{5}$, $B = -\frac{3}{5}$, and $C = \frac{2}{5}$. On the right side, the Laplace transform is defined as $\mathcal{L}\{f(t)\} = \int_0^{\infty} f(t)e^{-pt} dt = F(p)$. Two inverse Laplace transform formulas are also shown: $\mathcal{L}^{-1}\left\{\frac{1}{p^{n+1}}\right\} = \frac{t^n}{\Gamma(n+1)}$ and $\mathcal{L}^{-1}\left\{\frac{1}{p^2+a^2}\right\} = \frac{1}{a} \sin at$.

So, this is a linear part, and this is a quadratic part. So, how to find out Laplace inverse of this $F(p)$? So, this can be written as. Now we will make use of partial fractions. First we will try to reduce into partial fractions, and then we will try to find out its Laplace inverse. So, it can be written as a upon p minus 1 plus.

Now, since it is a quadratic part. So, in the numerator we will be having a linear term, linear in p . So, it will be something b p plus c upon p square plus 4. So, compare the coefficients from the both side, this implies p plus 2 will equal to this into this; that is a into p square plus 4 and plus b p plus c into p minus 1. Now we have to compute the values of a , b and c first. So, we can make use of; compare the coefficients of the both sides. Here the coefficient of p square is a , from here it is b and here there is no term involving p square, so a will be 0.

And the coefficient of p here is 0, and the coefficient of p here is $-b$ plus c , and here it is 1, so it will be 1. And the constant here is $4a$ minus c that here constant is 2. So, we are having 3 equations with 3 unknowns. So, we can find the values of a , b and c . So, a here we have already obtained actually. So, a is $\frac{3}{5}$, b is $-\frac{3}{5}$ and c is $\frac{2}{5}$. This we can easily compute by solving these 3 equations.

(Refer Slide Time: 25:48)

$$F(p) = \frac{p+2}{(p-1)(p^2+4)}$$

$$= \frac{3}{5(p-1)} + \frac{-3p+2}{5(p^2+4)}$$

$$\mathcal{L}^{-1}\{F(p)\} = \frac{3}{5} \mathcal{L}^{-1}\left\{\frac{1}{p-1}\right\} - \frac{3}{5} \mathcal{L}^{-1}\left\{\frac{p}{p^2+4}\right\} + \frac{2}{5} \mathcal{L}^{-1}\left\{\frac{1}{p^2+4}\right\}$$

$$= \frac{3}{5} e^t - \frac{3}{5} \cos 2t + \frac{1}{5} \times \frac{1}{2} \sin 2t$$

$$= \frac{3e^t - 3\cos 2t + \sin 2t}{5}$$

$$\mathcal{L}\{f(t)\} = \int_0^{\infty} f(t) e^{-pt} dt = F(p)$$

$$\mathcal{L}^{-1}\left\{\frac{1}{p^{n+1}}\right\} = \frac{1}{\Gamma(n+1)} t^n$$

$$\mathcal{L}^{-1}\left\{\frac{1}{p^2+a^2}\right\} = \frac{1}{a} \sin at$$

So, once we obtained the values of a b and c, then it is nothing, but, sorry it is nothing, but 3 by 5 times this, it is minus 3 plus 2 upon 5. Now the Laplace inverse of this F p will be nothing, but 3 by 5 times Laplace inverse of 1 upon p minus 1 minus 3 by 5 times Laplace inverse of p upon p square plus 4 plus 2 by 5 times Laplace inverse of 1 upon p square plus 4.

So, this is nothing, but 3 upon 5. Now Laplace inverse of 1 upon t minus a e k power a t here a is 1. So, Laplace inverse of 1 upon p minus a t is e k power t minus 3 by 5 Laplace inverse of this is cos 2 t. So, it will be cos 2 t a is 2, and here for this, it is plus 2 by 5 Laplace inverse of this expression a is 2. So, it will be nothing, but 1 by 2 times sin 2 t. So, the final answer is e k power 3 t e into 3 e k power t minus 3 cos 2 t this 2 cancels out plus sign 2 t upon 5.

So, we have seen that how we can Laplace transform of some standard functions; like sin a t cos a t sin hyperbolic a t or cos hyperbolic a t, and using these Laplace transforms, how we can find out Laplace transform of some functions or inverse Laplace transforms.

Thanks.
