**Lecture – 25**  
**Existence theorem for Laplace Transforms**

Hello everyone, we have already discussed what Laplace transforms are, and basically what are the Laplace transforms of some standard functions like  $t^k$  power  $n$  or  $e^{kt}$  power  $a$  or  $\sin at$ ,  $\cos at$  that we have already discussed. Now, we will see what is the existence theorem for Laplace transforms that means, what are the condition the function  $f(x)$  or  $f(t)$  must hold, so that we can say that Laplace of  $f(t)$  exist. How can we guaranty that the function posses, if the function posses these properties then the Laplace transform of  $f$  a function where exist.

So, in this topic, in this lecture, we will deal with existence theorem that what are the conditions so function should have, so that we can say the Laplace transform of function exist. So, before defining existence theorem for Laplace transforms, we will deal with two terms; one is piecewise continuous function, and second is exponential order.

(Refer Slide Time: 01:38)

**Existence theorem for Laplace transforms**

Before stating the existence theorem for Laplace transforms, we define the following two terms:

(i) **Piecewise continuous function:** If for an interval  $0 \leq a \leq t \leq b$ , there are at most a finite number of points  $t_k$ ,  $k = 1, 2, \dots, r$  and  $t_{k-1} < t_k$ , at which the function  $f(t)$  has finite jumps/discontinuities and is continuous on each such interval  $t_{k-1} < t < t_k$ , then such type of function  $f(t)$  is called a piecewise continuous function.

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    2

So, what is piecewise continuous function? Now, we already know what are continuous function is continuous function means if you are talking about continuous function that

means, that the limit of the function at that point exist and that must be equal to value of the function at that point.

(Refer Slide Time: 02:02)

If you are talking about continuity, so continuity means limit  $x$  tending to  $a$   $f(x)$  must be equals to  $f(a)$ . So, this means function  $f$  is continuous at  $x$  equal to  $a$ , that means if this limit exist that means, left hand limit is equal to right hand limit and that is equals to the value of the function at that point. So, we say there is a function is continuous at that point.

Now, if it holds over line that domain of the function then we say the function is a continuous over the entire domain  $d$  suppose. Now, what do we mean by piecewise continuous function? Suppose, we have an interval and in that interval function have some discontinuity, but if we break the function into finite number of subintervals and in each subintervals function is continuous, then we say that function is piecewise continuous. That means, suppose you have a interval  $0$  to  $b$  suppose you have some interval  $0$  to  $b$ , you divide that interval into finite number of subintervals in each subinterval function is continuous, but at the end points function as some discontinuity and that two of jump discontinuity then we say that the function is piecewise continuous.

(Refer Slide Time: 03:45)

Example of a piecewise continuous function

$$f(x) = \begin{cases} x^2 & \text{if } 0 \leq x < 5, \\ 7 & \text{if } 5 \leq x < 8, \\ 9 - x & \text{if } 8 \leq x \leq 9 \end{cases}$$

The function  $f(x)$  consists of three continuous pieces separated by two discontinuities at  $x = 5$  and  $x = 8$ . Hence the function  $f(x)$  is piecewise continuous in the interval  $[0, 9]$ .

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

We will illustrate this definition by an example.

(Refer Slide Time: 03:52)

Now, suppose  $f(x)$  is equal to  $x^2$  when  $x$  is between 0 to 5 and so  $f(x)$  equal to  $x^2$ . Now, it is 0, 1, 2, 3, 4, 5; between 0 to 5 this is  $x^2$  that is something like this, this is 5. And from 5 to 8, the function has value 7. So, this is some 7 point here suppose, so function is 7 here. From 5 to 8 function is it is 6, 7, 8 function is 8. At  $f$  equal to 8, function is though we have a hollow here, we have a circle point bold point here. And at  $x$  equal to 5, this we have a bold here. Now, from  $x$  equal to 8 to 9, we have a

function  $9 - x$ . So, at  $x$  equal to 8, function will be function value of when we put  $x$  equal to 8 here, so  $9 - 8$  is 1. So, function as a value 1. So, suppose one is here. So, suppose function has a value one here when  $x$  is 8. And 8 to 9 function is 9 at 9 is 0, at 9 it is 0 function as straight line positive function here.

So, this is how this function looks like geometrically. From 0 to 5 function is  $x^2$ ; from 5 to 8 function is a straight line having the value 7; from 8 to 9 again it is a straight line the given by  $9 - x$ . Now, if we take, if we see this function from 0 to 9, 0 to 9 function discontinuous; at which point function at discontinuous - two points we have  $x$  equal to 5 and  $x$  equal to 8, where function have discontinuity. And the nature of discontinuity is jump type, jump type means it have discontinuity, but value is some, but it is not going to infinity.

You see that  $x$  equal to 5, if we approach from left hand side the value is  $x^2$  or 25; and where the approach from right hand side the value is 7. At  $x$  equal to 8, if we approach from the left hand side, the value is 7; and if we approach from right hand side the value is 1. So, function have two discontinuity at  $x$  equal to 5 and  $x$  equal to 8. So, if we see from 0 to 5, 0 to 5 the function is continuous; from 5 to 8, function is continuous; from 8 to 9, function is continuous. So, if we break this interval 0 to 9 into three subintervals 0 to 5, 5 to 8, 8 to 9 in each three subintervals function is continuous. And it is having two discontinuity  $x$  equal to 5 and  $x$  equal to 8. So, this function we say as piecewise continuous function, because as a whole function is not continuous, but if we divide this function into finite number of subintervals in each subinterval function is continuous. So, we say the function is piecewise continuous function.

(Refer Slide Time: 07:32)

Continued...

(ii) **Exponential order:** A function  $f(t)$ ,  $t \geq 0$  is said to be of exponential order  $\alpha$  if there exist constants  $\alpha$ ,  $K > 0$  and  $T > 0$  such that

$$|f(t)| \leq Ke^{\alpha t}, \quad t > T.$$

Hence, if a function  $f$  is of exponential order  $\alpha$ , then

$$\lim_{t \rightarrow \infty} |f(t)e^{-\alpha t}| \text{ is finite.}$$

VT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    4

Now, the next is, the next point is the next definition is exponential order. Now, what do we mean by exponential order? Now, let us see this also. Now, a function  $f(t)$ ,  $t$  greater than equal to 0 is set to of exponential order  $\alpha$ .

(Refer Slide Time: 07:54)

$|f(t)| \leq Ke^{\alpha t}, \quad t > T$

$|e^{-\alpha t} f(t)| \leq K, \quad t > T$

$\lim_{t \rightarrow \infty} e^{-\alpha t} f(t) = \text{finite}$

$|e^{2t} \sin t| = |e^{2t}| |\sin t| \leq e^{2t}$

If there exist  $\alpha$ ,  $k$  and  $t$  greater than 0, such that  $|f(t)| \leq k e^{\alpha t}$  for  $t$  greater than  $t$ . So, if for a function  $f(t)$ , this condition hold there exist some  $\alpha$  and  $k$  such that this condition hold then we say that the function is of exponential order  $\alpha$ . Now, what does mean geometrically? It means that the

absolute value of the function of  $f$  does not grow faster than the exponential function. This value is this mod of this value or less than equal to this value that means, the absolute value of the function  $f$  does not grow faster than exponential order that is  $e^k$  power  $\alpha t$ , for any  $t$ , for all  $t$ . If this holds for all  $t$ , though we say that the function is a exponential order  $\alpha$ .

Now, we can also see that this is minus  $e^k$  power  $\alpha t$   $f t$  modules will be less than equal to  $k$  as  $t$  tending  $t$  that means, if becomes very large tending to infinity then this value is always finite because it is less than equal to  $k$ . So, that means that limit  $t$  tending to infinity  $e^k$  power minus  $\alpha t$   $f t$  must be finite value. It is a finite value. So, if a function is a exponential order  $\alpha$  then for that  $\alpha$  this quantity as  $t$  tend to infinity must tends to a finite quantity. So, this is the result of the exponential order  $\alpha$  from the definition we get this result.

(Refer Slide Time: 10:03)

**Examples of exponential order functions**

- (i)  $f(t) = t$  is of exponential order 1 since  $|t| \leq e^t, t \geq 0$ .
- (ii)  $f(t) = \cos 2t$  is of exponential order 1 since  $|\cos 2t| \leq e^t, t \geq 0$ .
- (iii)  $f(t) = e^{2t} \sin 2t$  is of exponential order 2 since  $|e^{2t} \sin 2t| \leq e^{2t}, t \geq 0$ .
- (iv)  $f(t) = t^2$  is of exponential order 3 since  $|t^2| \leq e^{3t}, t \geq 0$ .

**Example of a function not of any exponential order**

The function  $f(t) = e^{2t^2}$  is not of exponential order for any  $\alpha$ .

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

Now, we have some functions examples of exponential order  $\alpha$ . Now, if we see  $f t$  equal to  $t$  the first function  $f t$  equal to  $t$ , it is clearly of exponential order  $\alpha$  exponential order 1, where  $\alpha$  is 1, since mod of  $t$  is always less than  $e^k$  power  $t$ . You can visualize graphically also. If we see the graph of  $t$  when  $t$  is greater than equal to 0 is straight line is a straight line as  $t$  is a straight line, and  $e^k$  power  $t$  graph of  $e^k$  power  $t$  is something like this at  $t$  equal to 0  $m$  and this is it is something like this. So,  $e^k$  power  $t$  is always greater than equals to mod of  $t$  when  $t$  is greater than equal to 0 that means, there

are exist some  $k$  which is 1 here, and there are exist  $\alpha$  which is 1 for which this definition holds. So, we say that  $f(t)$  is equal to  $t$  is a exponential order 1.

Similarly  $f(t) = \cos^2 t$  is also exponential order one since  $\cos^2 t$  is less than equal to  $e^{-k} t$ . Again we visualize the same definition graphically  $f(t) = e^{-k} t^2 \sin^2 t$  is of exponential order 2. Since if you take mod of this quantity mod of  $e^{-k} t^2 \sin^2 t$ , so it is nothing but it is equals to mod of  $e^{-k} t^2$  into mod of  $\sin^2 t$ . And mod of  $\sin^2 t$  is always less than equals to 1 for any  $t$ , so it always less than equals to  $e^{-k} t^2$ . So, here if we compare with this definition there exist  $k$  equal to 1 and  $\alpha$  equal to 2, so that means, this definition holds. And since  $\alpha$  is 2, so we say that this function  $e^{-k} t^2 \sin^2 t$  is of exponential order 2. Similarly,  $f(t) = t^3$  is also of exponential order 3, since mod of  $t^3$  is less than equals to  $e^{-k} t^3$ . This also we can prove also and we can visualize geometrical also that this inequality hold.

Now, we have also an example which is not of any exponential order I mean is not of exponential order of any  $\alpha$ , for any  $\alpha$ . So, what does it means, how can we say this? Now, we have seen that if a function of exponential order  $\alpha$ , then  $\lim_{t \rightarrow \infty} e^{-k} t^{-\alpha} f(t)$  tends to a finite quantity. Now, let us check whether this function  $f(t) = e^{-k} t^2$  holds that property or not it is that property or not satisfied that property or not.

(Refer Slide Time: 12:49)

$$\begin{aligned}
 f(t) &= e^{2t^2} \\
 \lim_{t \rightarrow \infty} e^{-\alpha t} f(t) &= \lim_{t \rightarrow \infty} e^{-\alpha t} e^{2t^2} \\
 &= \lim_{t \rightarrow \infty} e^{2(t^2 - \frac{\alpha}{2}t)} = \lim_{t \rightarrow \infty} e^{2\left[t^2 - \frac{\alpha}{2}t + \frac{\alpha^2}{16} - \frac{\alpha^2}{16}\right]} \\
 &= \lim_{t \rightarrow \infty} e^{2\left[\left(t - \frac{\alpha}{4}\right)^2 - \frac{\alpha^2}{16}\right]} \\
 &= \lim_{t \rightarrow \infty} e^{2\left(t - \frac{\alpha}{4}\right)^2 - \frac{\alpha^2}{8}} \\
 &\rightarrow \infty
 \end{aligned}$$

So, what is  $f(t)$  here, what is  $f(t)$  now?  $f(t)$  is  $e^{k \text{ power } 2t^2}$ . So, you find  $e^{k \text{ power } 2t^2}$  minus  $\alpha t$  into  $f(t)$ , this limit as  $t$  tending to infinity. We try to find this limit, because if it is of exponential order  $\alpha$ , so this limit must tend to a finite quantity. If it is not tending to a finite quantity this means, it is not a exponential order for any  $\alpha$ . So, here we are taking an arbitrary  $\alpha$ , so  $\alpha$  may be any constant. So, for this particular problem, so  $t$  tending to infinity  $e^{k \text{ power } 2t^2}$  minus  $\alpha t$ , what is  $e^{k \text{ power } 2t^2}$  minus  $\alpha t$ ? So, this is nothing but limit  $t$  tend into infinity  $e^{k \text{ power } 2t^2}$  minus  $\alpha t$  by two times  $t$ .

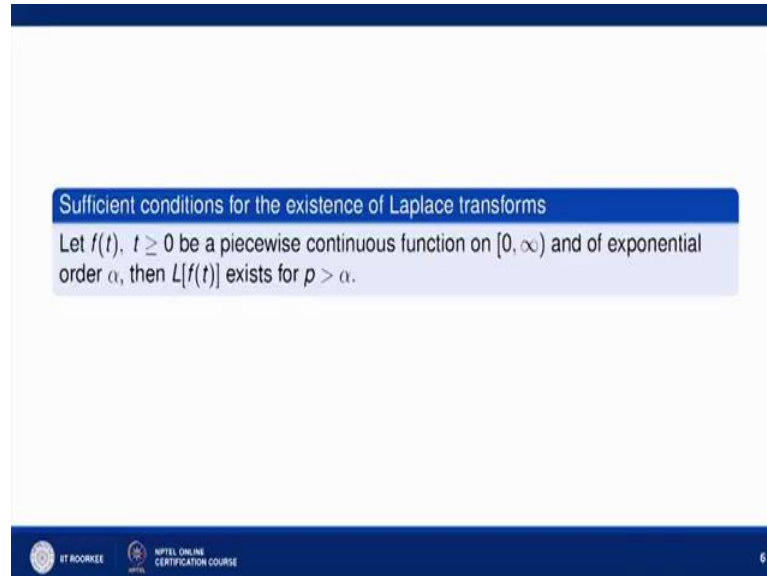

Now, this is nothing but is equal to this is equal to limit  $t$  tend into infinity  $e^{k \text{ power } 2t^2}$  minus  $\alpha t$  now we will make perfect square here, here is  $t^2$ , here is minus  $\alpha t$  by 2 times  $t$ . So, we will add and subtract  $\alpha^2$  by 4 in this expression. So, it is  $2t^2$  minus  $\alpha t$  by 2 plus  $\alpha^2$  by 4 minus  $\alpha^2$  by 4. So, let us see limit  $t$  tending to infinity, it is  $e^{2t^2}$ , it is  $(t - \frac{\alpha}{4})^2$  minus  $\frac{\alpha^2}{16}$ . So, since  $\alpha^2$  by 4 square, so we have to subtract  $\alpha^2$  by 16 here add and subtract  $\alpha^2$  by 16. So, it will make it perfect square and minus  $\alpha^2$  by 16.

Now, when you take limit as  $t$  tending to infinity, since it has a positive coefficient of  $t^2$  here as  $e^{k \text{ power } 2t^2}$  positive coefficient of  $t^2$ , so it will tends to infinity of course, So, it will tends to infinity. So, this means that it is not of exponential order for any  $\alpha$  because we have taken  $\alpha$  is a arbitrary constant. So, this if we take any  $\alpha$ , this

always tend to infinity, so we can say that this function  $e^{k t^2}$  is not of exponential order for any  $\alpha$ .

(Refer Slide Time: 16:07)

Now, we come to sufficient condition for the existence of the Laplace transforms. So, we have already seen what are piecewise continuous functions. And when we say, there a function of a exponential order  $\alpha$ . Now, if  $f(t)$  is piecewise continuous function for  $t$  greater than equal to 0 and is of exponential order  $\alpha$  then Laplace transform  $f(t)$  always exists, this is sufficient condition for the existence of Laplace transform. So, for the existence condition two conditions must hold; if function is piecewise continuous and exponential order  $\alpha$  then Laplace transform of that function always exists, this we can surely say; now what is a proof of this, now how can we say this though proof is very simple.

(Refer Slide Time: 16:44)

$$\begin{aligned}
 \mathcal{L}\{f(t)\} &= \int_0^{\infty} e^{-pt} f(t) dt \\
 &= \int_0^T e^{-pt} f(t) dt + \int_T^{\infty} e^{-pt} f(t) dt, \text{ for any } T > 0. \\
 \left| \int_T^{\infty} e^{-pt} f(t) dt \right| &\leq \int_T^{\infty} |e^{-pt} f(t)| dt \\
 &\leq \int_0^{\infty} |e^{-pt} f(t)| dt \\
 &\leq \int_0^{\infty} e^{-pt} k e^{\alpha t} dt = k \int_0^{\infty} e^{-(p-\alpha)t} dt = k \left( \frac{e^{-(p-\alpha)t}}{-(p-\alpha)} \right)_0^{\infty} \\
 &= \frac{k}{p-\alpha}
 \end{aligned}$$

Now, what is Laplace transform of  $f(t)$ , it is nothing but  $\int_0^{\infty} e^{-pt} f(t) dt$ , this is how we define Laplace transform. Now, this can be written as  $\int_0^T e^{-pt} f(t) dt + \int_T^{\infty} e^{-pt} f(t) dt$ , this is for any  $T$ . For any  $T$  greater than 0 for any  $t$  greater than 0, we can always break this  $\int_0^{\infty}$  as  $\int_0^T + \int_T^{\infty}$ . Now, since  $f(t)$  is piecewise continuous, it is given  $f(t)$  is piecewise continuous that means, it has a discontinuity and that also jump type and interval is finite  $0$  to  $t$ . So, interval is finite and  $f(t)$  is piecewise continuous. So, this value always exist, existence means this values always have some finite value finite quantity, this value have some finite value. This expression has some finite value.

Now, what about this, how can we say that this also have a finite value. So, to see this, now what this expression is this is  $\int_T^{\infty} e^{-pt} f(t) dt$ . So, if you take the mod of this, so this is less than or equals to  $\int_T^{\infty} |e^{-pt} f(t)| dt$ . This is by the result of integration. Now, this can be less than equals to  $\int_0^{\infty} |e^{-pt} f(t)| dt$ , because if we increase the size of the interval here then the value will increase definitely, because this quantity is will always positive. Here we have  $\int_0^{\infty}$  here we are increasing the interval from  $0$  to  $\infty$ , so value of this expression will be always more than the value of this expression.

Now, this now since we know that  $f(t)$  is a exponential order  $\alpha$ . So, by the definition exponential order  $\alpha$ , this quantity is always less than equals to  $\int_0^{\infty} e^{-pt} k e^{\alpha t} dt$

$\int_0^{\infty} k e^{-k t} e^{\alpha t} dt$ , these all are positive quantity. So, mod can be removed. Now, this is equal to  $k$ , we can take common  $0$  to infinity  $e^{-k t} e^{\alpha t} dt$ . So, this integration is nothing but  $k$  times  $e^{-k t} e^{\alpha t}$  from  $0$  to infinity. And since  $p$  is greater than  $\alpha$ , so for greater than  $\alpha$  this quantity  $p - \alpha$  is positive.

Now, we have an negative outside as  $t$  tending to infinity this will tend to  $0$ . And at  $t$  equal to  $0$ , this will tends to  $k$  upon  $p - \alpha$ . So, we have shown that this quantity is always less than equal to this quantity which is a finite number, finite real number. So, if this expression is less than equal to this expression this means this expression is also have some finite value, and finite value plus finite value is again a finite value that means, Laplace of  $f(t)$  will exist, because for existence this must we have some finite value. So, we have shown that Laplace transform of  $f(t)$  exist if it is a piecewise continuous function and exponential order  $\alpha$ .

So, we break this function into two parts, since this function is piecewise continuous limit is finite. So, this value will always exist, exist means having some finite value and this because  $f(t)$  is of exponential order  $\alpha$ . So, by this calculation, we have shown that this value is always less than equal to some finite value that means, that expression also exist. So, hence the Laplace transform of  $f(t)$  exist.

Now, important point to note here is if function is piecewise continuous and exponential order  $\alpha$ , then Laplace exist; there is no doubt in that, because that is we have shown also that is the sufficient condition. Otherwise, if a function suppose not of exponential order or is not of piecewise continuous, then Laplace transform may or may not exist we cannot say, this is only a sufficient condition.

(Refer Slide Time: 22:13)

**Remark**

It may be possible that  $\mathcal{L}[f(t)]$  exists even when the sufficiency conditions do not hold. For example,

$$f(t) = t^{-1/2}$$

For any interval  $[0, T]$ , the function  $f(t)$  is discontinuous since as  $t \rightarrow 0$  from right, the limit tends to  $\infty$ . However, the Laplace transform of  $f(t)$  exists.

VT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

So, we have an example also. Suppose we have example  $f(t)$  equal to  $t^k$  power minus half, if we see this example, this problem  $f(t)$  equal to  $t^k$  power minus half.

(Refer Slide Time: 22:25)

$f(t) = t^{-k/2}$

$[0, T]$

$\lim_{t \rightarrow 0^+} f(t) = t^{-k/2} \rightarrow \infty$

$\mathcal{L}\{t^{-k/2}\} = \frac{\Gamma(-k/2)}{p^{k/2}} = \frac{\Gamma(\frac{1}{2})}{\sqrt{p}}$

Now, the interval is, now you take any interval from 0 to  $t$ , for any  $t$ , you take any  $t$  no matter how small you are taking or no matter how big you are taking, you take any  $t$  0 is always in the interval. Now, from the right side of the 0, if you take the limit  $t$  tending to 0 that means, if you take this limit, limit  $t$  tending to 0 plus of  $f(t)$  that is limit  $t$  tending into 0 plus of  $t^k$  power minus half. So, of course, it will tend to infinity from the right

hand side so that means, this function is not piecewise continuous because if it is piecewise continuous, so it must have jump discontinuities. So, this limit tending to infinity that means, this function is not piecewise continuous, but its Laplace exist.

How, because Laplace of  $t^k$  power minus half will be nothing but gamma minus half plus 1 upon  $p^k$  power minus half plus 1, because Laplace of  $t^k$  power n is nothing but gamma n plus 1 upon  $p^k$  power n plus 1 here n is minus half. So, it is nothing but gamma half upon  $p^k$  power half and gamma half is under root pi. So, it is under root pi by p. So, hence Laplace exist, however, it does not satisfied sufficient condition, so that means, if Laplace of function is piecewise continuous and in an exponential order alpha then surely Laplace exist otherwise we cannot say, so that is the that is only the sufficient condition.

(Refer Slide Time: 24:38)

The slide contains the following text:

**Behavior of  $F(p)$  as  $p \rightarrow \infty$**

Let  $f(t)$  be a piecewise continuous function for  $t \geq 0$  and is of exponential order  $\alpha$ .  
 Let  $L[f(t)] = F(p)$ , then

- (i)  $\lim_{p \rightarrow \infty} F(p) = 0$ ,
- (ii)  $\lim_{p \rightarrow \infty} [pF(p)]$  is bounded.

At the bottom of the slide, there are logos for 'IT ROORKEE' and 'NIPER ONLINE CERTIFICATION COURSE' along with the number '8'.

So, next is behavior of  $p$ , as  $p$  tending to infinity  $F(p)$ . So, let  $F(p)$  be a piecewise continuous function and is an exponential order alpha. Now, while you assume this condition always because by the sufficient condition we know that for the existence of the Laplace transform we must have if we state some theorem, so we need the existence of Laplace theorem. So, for that we are assuming that the function is piecewise continuous and is of exponential order alpha. Now, we have to prove now if Laplace of  $f(t) = F(p)$  then limit  $p$  tend into infinity  $F(p)$  is always 0.

(Refer Slide Time: 25:12)

This is; what is  $F(p)$ ,  $F(p)$  is nothing but Laplace of  $f(t)$ . What is Laplace of  $f(t)$ ? It is  $\int_0^{\infty} e^{-pt} f(t) dt$ . Now, it is again we can write it like this  $\int_0^T e^{-pt} f(t) dt + \int_T^{\infty} e^{-pt} f(t) dt$  for any  $T > 0$ . Now, for this quantity again, if this quantity  $\int_T^{\infty} e^{-pt} f(t) dt$  if it is this quantity, so this quantity less than equals to  $\int_T^{\infty} |e^{-pt} f(t)| dt$  and since  $f$  is of exponential order  $\alpha$ . So, therefore, this is less than equals to  $\int_0^{\infty} |e^{-pt} k e^{\alpha t}| dt$  and taking the limit  $\lim_{p \rightarrow \infty} \int_0^{\infty} |e^{-pt} k e^{\alpha t}| dt = \frac{k}{p-\alpha}$ .

Now, as we take limit  $p \rightarrow \infty$   $\lim_{p \rightarrow \infty} F(p)$ , so that means,  $\lim_{p \rightarrow \infty} \int_0^T e^{-pt} f(t) dt + \lim_{p \rightarrow \infty} \int_T^{\infty} e^{-pt} f(t) dt$ . So, now, this expression, now when we take limit  $T \rightarrow \infty$  this expression, so this will be less than equals to this quantity as  $p \rightarrow \infty$  this quantity tend into 0 so that means, limit of this expression is less than equal to 0 that means, limit of quantity is equal to 0. As  $p \rightarrow \infty$  since this quantity having some finite value, so as  $p \rightarrow \infty$  since we have a  $e^{-pt}$  here and  $f$  is a piecewise continuous function. So, this value tending to 0. So, we can say that this quantity tending to 0 this quantity also tending to 0. So, this quantity will be equal to 0 or tends to 0.

So, this is the first result that limit  $p$  tend into infinity  $F(p)$  will be 0. Because if we take limit  $p$  tending to infinity here, so this quantity will tend to 0, and this quantity is also tend to 0 by in quality as  $p$  tend into infinity this tending to 0. So, this quantity will tend to 0, so hence 0 plus 0 is 0. So, what does it mean, it mean that whenever function is piecewise continuous and it is of exponential order  $\alpha$  then limit  $p$  tending to infinity  $F(p)$  is always 0.

(Refer Slide Time: 29:19)

The image shows a whiteboard with handwritten mathematical derivations. The first line defines the Laplace transform:  $pF(p) = \mathcal{L}\{f(t)\} = p \int_0^{\infty} e^{-pt} f(t) dt$ . The second line shows the limit as  $p \rightarrow \infty$  of  $pF(p)$  as the sum of two integrals:  $\lim_{p \rightarrow \infty} pF(p) = \lim_{p \rightarrow \infty} \left( \int_0^T p e^{-pt} f(t) dt + \int_T^{\infty} p e^{-pt} f(t) dt \right)$ . The third line shows an inequality for the second integral:  $\left| \int_T^{\infty} p e^{-pt} f(t) dt \right| \leq \frac{kp}{p-\alpha}$ . The fourth line shows the limit of this inequality:  $\lim_{p \rightarrow \infty} \left| \int_T^{\infty} p e^{-pt} f(t) dt \right| \leq k$ .

Now, the second result that limit  $p$  tending to infinity  $pF(p)$  is bounded. So, again we can show using the same definition  $p$  into  $pF(p)$  into Laplace transform of  $f(t)$ . So,  $p$  into it is 0 to infinity  $e^{-kt} f(t) dt$ , it is nothing but again 0 to  $t$  into  $e^{-kt} f(t) dt$  plus  $t$  to infinity  $p$  into  $e^{-kt} f(t) dt$ . Now, limit  $p$  tending to infinity of  $pF(p)$  will be nothing but limit  $p$  tend into infinity of this whole expression. Now, this quantity we have already seen that mod of this quantity  $p$  into  $e^{-kt} f(t) dt$  this quantity that we have already seen that if it is not  $p$  here, so this expression is less than equals to  $k$  upon  $p - \alpha$ . This we have just shown using the property of exponential order because  $f$  is of exponential order  $\alpha$ . So, we can say that since  $p$  is here, so this quantity will be less than equals to  $k$  upon  $p - \alpha$ . So, as limit  $p$  tending to infinity, so this expression will be less than equals to  $k$  because this is tending to 1.

Now, this expression - the second expression is  $p$  tending to infinity is always less than equals to  $k$  as  $p$  tending to infinity. And the first expression, where you take  $p$  tend into infinity, so this is if you take here limit  $p$  tend into infinity, so this is tending to 0. So, we can say that this limit is always bounded because what we have finally coming to 0 plus less than equal to  $k$  that means, this expression is always less than equal to  $k$  that means, this limit is always bounded. So, the second result that limit  $p$  tend to infinity  $p F p$  is always bounded. So, again if  $p F p$  is not bounded, so we can say that they does not exist any piecewise continuous function, whose Laplace transform is that  $F p$ .

Thank you very much.
