Lecture – 26
Properties of Laplace Transforms-I

Hello everyone, so in the last lecture, we have seen that what is the existence theorem for Laplace transforms. We have seen that if a function is a piecewise continuous and is of exponential order alpha then its Laplace transform always exists; otherwise if function is not piecewise continuous or is not of exponential order then Laplace may or may not exist that also we have seen. So, now in this topic, we will see what are the properties of Laplace transforms.

(Refer Slide Time: 01:04)

The slide contains two sections, each with a blue header and a light blue background for the text. The first section is titled 'First translation or shifting property' and states that if $L[f(t)] = F(p)$, then $L[e^{at}f(t)] = F(p - a)$. The second section is titled 'Second translation or shifting property' and states that if $L[f(t)] = F(p)$ and $G(t) = \begin{cases} f(t - a) & \text{if } t > a, \\ 0 & \text{if } t < a, \end{cases}$ then $L[G(t)] = e^{-ap}F(p)$. At the bottom of the slide, there are logos for IIT Roorkee and NPTEL Online Certification Course, along with the number 2.

So, we will start with the first property that we call as shifting property. Now, shifting property is first we have first translation and then we have second translation of the shifting property.

(Refer Slide Time: 01:20)

The image shows a handwritten derivation of the first translation theorem for Laplace transforms. It starts with the definition of the Laplace transform of a function $f(t)$ as $F(p)$. Then, it states that the Laplace transform of $e^{at}f(t)$ is $F(p-a)$. The derivation then shows the integral definition of the Laplace transform of $e^{at}f(t)$, which is $\int_0^{\infty} e^{at}f(t)e^{-pt}dt$. This is simplified to $\int_0^{\infty} e^{-(p-a)t}f(t)dt$. Then, a substitution $\psi = p-a$ is made, leading to the integral $\int_0^{\infty} e^{-\psi t}f(t)dt$, which is identified as $F(\psi) = F(p-a)$.

$$\begin{aligned} \text{If } L\{f(t)\} &= F(p) \\ \text{Then } L\{e^{at}f(t)\} &= F(p-a) \\ L\{e^{at}f(t)\} &= \int_0^{\infty} e^{at}f(t)e^{-pt}dt \\ &= \int_0^{\infty} e^{-(p-a)t}f(t)dt \\ &= \int_0^{\infty} e^{-\psi t}f(t)dt, \quad \psi = p-a \\ &= F(\psi) = F(p-a) \end{aligned}$$

What is first translation? First translation means if Laplace transform of $f(t)$ is say $F(p)$ then if this holds then Laplace transform of e^{kt} into $f(t)$ is nothing but $F(p-a)$. That means if we know the Laplace transform of $f(t)$ which is given as $F(p)$ if you know this then Laplace transform of e^{kt} into $f(t)$ is nothing but you simply replace p by $p-a$. So, then we will get the Laplace transform of this function e^{kt} into $f(t)$. Now, what are the proof of this result, how we will obtain this result? Now, what is Laplace transform of e^{kt} into $f(t)$ by the definition? This is nothing but $\int_0^{\infty} e^{kt}f(t)e^{-pt}dt$, this is by the definition of Laplace transform.

So, this is equal to $\int_0^{\infty} e^{-(p-a)t}f(t)dt$. So, this is nothing but $\int_0^{\infty} e^{-\psi t}f(t)dt$ where ψ is nothing but $p-a$. Then this quantity is nothing but $F(\psi)$ because what is $F(p)$, $F(p)$ is Laplace of $f(t)$ which is $\int_0^{\infty} e^{-pt}f(t)dt$. So, instead of p , we have ψ in the same expression. So, we replace p as ψ and what is ψ ? ψ is $p-a$, so it is $p-a$. So, hence Laplace of e^{kt} into $f(t)$ is nothing but $F(p-a)$. So, simply replace p by $p-a$.

(Refer Slide Time: 03:42)

$$\begin{aligned} \text{If } \mathcal{L}\{f(t)\} &= F(p) \quad \& \quad G(t) = \begin{cases} f(t-a), & t > a \\ 0 & t < a \end{cases} \\ \text{then } \mathcal{L}\{G(t)\} &= e^{-ap} F(p). \\ \mathcal{L}\{G(t)\} &= \int_0^{\infty} e^{-pt} G(t) dt \\ &= \int_0^a e^{-pt} G(t) dt + \int_a^{\infty} e^{-pt} G(t) dt \\ &= 0 + \int_a^{\infty} e^{-pt} f(t-a) dt \end{aligned}$$

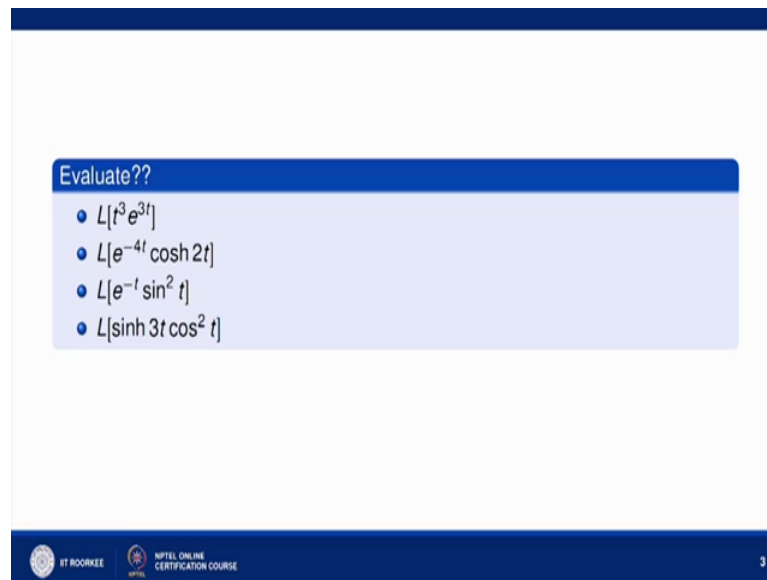

Now, second translation or the shifting property is if Laplace transform of $f(t)$ is $F(p)$, and $G(t)$ is given as $f(t-a)$, when $t > a$; and 0 when $t < a$ then Laplace transform of $G(t)$ is nothing but e^{-ap} times $F(p)$. Again we can prove this using the definition of Laplace transform, Laplace transform of $G(t)$ is nothing but we have to prove this result. So, this is equal to $\int_0^{\infty} e^{-pt} G(t) dt$ by the definition of Laplace transforms. This is equal to $\int_0^a e^{-pt} G(t) dt + \int_a^{\infty} e^{-pt} G(t) dt$ now $\int_0^a e^{-pt} G(t) dt$ is 0, because $G(t)$ is 0 and $t < a$, so it is 0, so this quantity 0 plus because $G(t)$ is 0. So, integration value will be 0 plus. So, this is $\int_a^{\infty} e^{-pt} f(t-a) dt$. When $t > a$, so $G(t)$ is $f(t-a)$. So, you simply take $f(t-a)$ here dt .

(Refer Slide Time: 05:45)

$$\begin{aligned} \mathcal{L}\{g(t)\} &= \int_a^{\infty} e^{-pt} f(t-a) dt \\ & \quad \begin{array}{l} t-a=z \\ dt=dz \end{array} \\ &= \int_0^{\infty} e^{-p(a+z)} f(z) dz \\ &= e^{-ap} \int_0^{\infty} e^{-pz} f(z) dz \\ &= e^{-ap} f(p) \end{aligned}$$

Now, this expression, so therefore, therefore, what is Laplace of $G t$. Therefore Laplace of $G t$ will be nothing but from here we got a into infinity e^{-k} power minus $p t$ of t minus a into dt . Now, you can take t minus a equal to some new variable say z , though dt will be dz . So, this will be equals to when t is a , so z will be 0 ; when t is tend into infinity, z tend into infinity e^{-k} power minus $p t$ from here a is a plus z . So, it is a plus z times $f z$ into dz . So, this is nothing but since e^{-k} power minus $p a$ is free from z , we are integrating it with respect to z . So, we can take it outside the integration e^{-k} power minus $a p$ 0 to infinity e^{-k} power minus $p z$ $f z$ dz , which is same as e^{-k} power minus $a p$. So, this is nothing but Laplace transform of $f t$ or $f z$, so this is $F p$. This is nothing but Laplace transform of $f t$. So, e^{-k} power minus $a p$ into $f p$. So, hence Laplace of $G t$ is nothing but e^{-k} power minus $a p$ into $F p$. So, this is called second translation or shifting property.

(Refer Slide Time: 07:30)

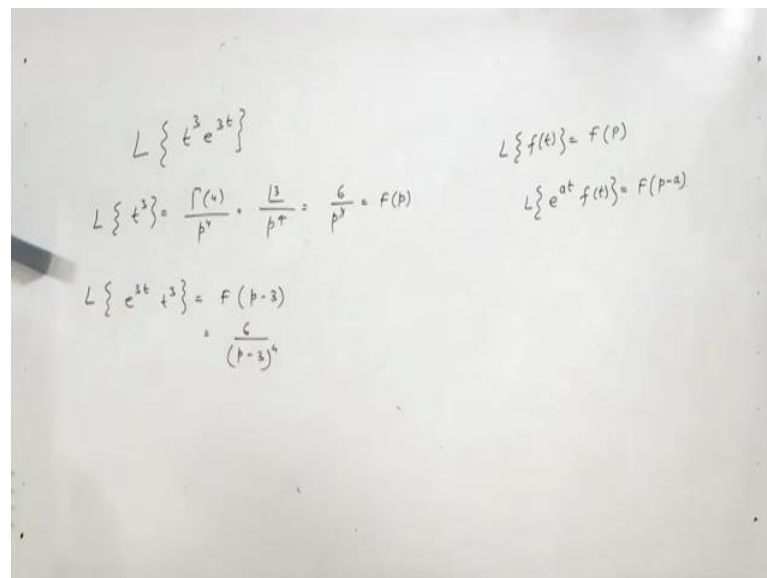

Evaluate??

- $L[t^3 e^{3t}]$
- $L[e^{-4t} \cosh 2t]$
- $L[e^{-t} \sin^2 t]$
- $L[\sinh 3t \cos^2 t]$

FT ROOKIEE NITEL ONLINE CERTIFICATION COURSE 3

Now, how we can solve problems based on this. Let us solve few examples on this. The Laplace transform of t cube e k power 3 t.

(Refer Slide Time: 07:34)

$L\{t^3 e^{3t}\}$

$$L\{t^3\} = \frac{\Gamma(4)}{p^4} = \frac{3!}{p^4} = \frac{6}{p^4} = F(p)$$
$$L\{e^{3t} t^3\} = F(p-3) = \frac{6}{(p-3)^4}$$

$L\{f(t)\} = F(p)$

$$L\{e^{at} f(t)\} = F(p-a)$$

So, we have just discussed that if Laplace transform of f t is F p then Laplace transform of e k power a t into f t is nothing but F of p minus a. So, here f t is t cube; if you compare this with this, so here f t is t cube. So, what is Laplace transform of t cube? It is gamma 4 upon p k power 4 this is nothing but factorial 3 upon p k power 4 which is nothing but 6 upon p k 4. So, 6 upon p k power 4. So, this is F p. Now, you have to

compute Laplace transform of e^{-kt} multiplied by t^3 . So, you simply replace $F(p)$ in $F(p)$ by $p - a$ and a here is 3, so that is nothing but $F(p - 3)$. So, that is nothing but $\frac{6}{(p - 3)^4}$, so that will be the Laplace transform of $t^3 e^{-kt}$.

Next problem, suppose the next problem is $e^{-4t} \cos 2t$. So, again here if you compare with this, so $f(t)$ is $\cos 2t$. So, first find Laplace of $\cos 2t$, let us put equal to $F(p)$ and then replace p by $p - a$, here a is minus 4. So, replace p by $p + 4$. So, what is Laplace transform of $\cos 2t$? We already know that Laplace transform of $\cos at$ is $\frac{p}{p^2 + a^2}$. So, it is $\frac{p}{p^2 + 4}$. So, Laplace transform of $e^{-4t} \cos 2t$ will be nothing but $F(p)$, you replace p by $p - a$, a is minus 4. So, $p + 4$, so that is nothing but $\frac{p + 4}{(p + 4)^2 + 4}$. So, this will be the Laplace transform of the $e^{-4t} \cos 2t$.

(Refer Slide Time: 10:40)

$$\begin{aligned} & \mathcal{L}\{e^{-t} \sin^2 t\} \\ & \mathcal{L}\{\sin^2 t\} = \mathcal{L}\left\{\frac{1 - \cos 2t}{2}\right\} \\ & = \frac{1}{2} \mathcal{L}\{1\} - \frac{1}{2} \mathcal{L}\{\cos 2t\} \\ & = \frac{1}{2p} - \frac{1}{2} \left(\frac{p}{p^2 + 4}\right) = F(p) \\ & \mathcal{L}\{e^{-t} \sin^2 t\} = F(p+1) = \frac{1}{2(p+1)} - \frac{p+1}{2((p+1)^2 + 4)} \end{aligned}$$

$$\begin{aligned} \mathcal{L}\{f(t)\} &= F(p) \\ \mathcal{L}\{e^{at} f(t)\} &= F(p-a) \end{aligned}$$

Now, the third problem, suppose you want to solve the third problem it is $e^{-t} \sin^2 t$. So, first find Laplace transform of $\sin^2 t$ put it equal to $F(p)$ and replace p by $p - a$, and here is a minus 1. So, replace p by $p + 1$. So, first find Laplace transform of $\sin^2 t$. So, $\sin^2 t$ is nothing but $\frac{1 - \cos 2t}{2}$. So, this is nothing but $\frac{1}{2}$ Laplace transform of $1 - \frac{1}{2}$ Laplace transform of $\cos 2t$.

t. So, Laplace transform of 1 is $\frac{1}{p}$ by p minus 1 by 2, Laplace transform of $\cos 2t$ is $\frac{p}{p^2 + 4}$. So, this whole is $F(p)$. Now Laplace transform of e^{kt} power minus t^2 will be nothing but $F(p-a)$ if you replace p by $p-a$, a is minus 1 that is $p+1$. So, that is nothing but $\frac{1}{2(p+1)}$ plus $\frac{p}{(p+1)^2 + 4}$, so that will be the Laplace transform of e^{kt} power minus $t^2 \sin^2 t$.

(Refer Slide Time: 12:26)

$$\begin{aligned} & \mathcal{L}\left\{\sinh 3t \cos^2 t\right\} \\ &= \mathcal{L}\left\{\left(\frac{e^{3t}-e^{-3t}}{2}\right) \cos^2 t\right\} \\ &= \frac{1}{2} \mathcal{L}\left\{e^{3t} \cos^2 t\right\} - \frac{1}{2} \mathcal{L}\left\{e^{-3t} \cos^2 t\right\} \\ & \mathcal{L}\left\{\cos^2 t\right\} = \mathcal{L}\left\{\frac{1+\cos 2t}{2}\right\} = \frac{1}{2p} + \frac{1}{2} \left(\frac{p}{p^2+4}\right) = F(p) \\ & \mathcal{L}\left\{e^{3t} \cos^2 t\right\} = F(p-3) \\ & \mathcal{L}\left\{e^{-3t} \cos^2 t\right\} = F(p+3) \end{aligned}$$

Again in the last problem, we can use shifting property, what is it? Is $\sinh 3t$ into $\cos^2 t$, it is nothing but Laplace of e^{kt} power 3 t minus e^{kt} power 3 t by 2 $\cos^2 t$. So, it is $\frac{1}{2}$ Laplace transform of e^{kt} power 3 t $\cos^2 t$ minus $\frac{1}{2}$ Laplace transform of e^{kt} power minus 3 t into $\cos^2 t$. So, we will find Laplace transform of $\cos^2 t$, put it equal to $F(p)$, and then in the first part replace p by $p-3$ and for the second part replace p by $p+3$.

So, what is Laplace transform of $\cos^2 t$? That again we can find out $\cos^2 t$ will be nothing but Laplace transform of $\frac{1+\cos 2t}{2}$ that is nothing but $\frac{1}{2}$. Laplace transform of 1 is $\frac{1}{p}$, so that is $\frac{1}{2p}$ plus $\frac{1}{2}$ Laplace transform of $\cos 2t$ is $\frac{p}{p^2 + 4}$. So, this is $F(p)$. Now, what is Laplace transform of this e^{kt} power 3 t $\cos^2 t$? This is nothing but $F(p-a)$. And what is Laplace transform of e^{kt} power minus 3 t $\cos^2 t$, this is nothing but $F(p+a)$. So, substituting these two values, you replace p by $p-3$ for the first

part, and you replace p by p plus 3 for the second part and you substitute these values here. So, we will get the Laplace transform of sin hyperbolic 3 t into cos square t.

(Refer Slide Time: 14:55)

$$\begin{aligned}
 & \mathcal{L} \left\{ t \sin 4t \right\} \\
 & \mathcal{L} \left\{ t \left(\frac{e^{4it} - e^{-4it}}{2i} \right) \right\} \\
 &= \frac{1}{2i} \mathcal{L} \left\{ t e^{4it} \right\} - \frac{1}{2i} \mathcal{L} \left\{ t e^{-4it} \right\} \\
 &= \frac{1}{2i} F(p-4i) - \frac{1}{2i} F(p+4i) \\
 &= \frac{1}{2i} \left[\frac{1}{(p-4i)^2} - \frac{1}{(p+4i)^2} \right] = \frac{1}{2i} \left(\frac{2 \times 4i \times p \times 2}{(p^2+16)^2} \right) = \frac{8p}{(p^2+16)^2}
 \end{aligned}$$

$\mathcal{L} \{ f(t) \} = F(p)$
 $\mathcal{L} \{ e^{at} f(t) \} = F(p-a)$
 $\mathcal{L} \{ t \} = \frac{1}{p^2} = F(p)$

Now, let us find Laplace transform of t sin 4 t. So, sin 4 t does not involve as such does not involve e k power a t, but we can break it. So, Laplace of t sin 4 t, so Laplace of t. Now, sin 4 t can be written as e k power 4 iota t minus e k power minus 4 iota t upon 2 iota, this is how we can replace sin 4 t. Now, this is nothing but 1 by 2 i Laplace transform of t into e k power 4 iota t minus 1 by 2 i Laplace transform of t into e k power minus 4 iota t. So, again here a is 4 iota, if you compare with this; and here a is minus 4 iota. So, you find Laplace of t first let it put it equal to F p, and for the first expression replace p by p minus 4 iota, and for second expression replace p by p plus 4 iota.

So, what is Laplace transform of t, what is Laplace transform of t? Laplace of t is nothing but 1 by p square, it is equals to F p. And for this part, it is nothing but 1 upon 2 iota f of p minus 4 iota minus 1 by 2 iota F of p plus 4 iota by this shifting property. So, this is nothing but 1 upon 2 iota. What is F of p minus 4 iota? 1 upon p minus 4 iota whole square minus 1 upon p plus 4 iota whole square. So, the simplify it 1 upon 2 iota into, so this will go here this will go here simplify it, so this is nothing but 2 a b 2 into 4 iota into p 2 a b into 2 again 2 1 2 again comes. Then it is nothing but p square plus 16 whole square, this 2 iota will cancel with 2 iota and this is nothing but 8 p upon p square plus 16 whole square. So, this will be the Laplace transformation of t sin 4 t.

(Refer Slide Time: 17:28)

$$L\{e^{-2t} \sin \sqrt{t}\}$$

$$\sin \theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} \dots$$

$$\sin \sqrt{t} = t^{1/2} - \frac{t^{3/2}}{3!} + \frac{t^{5/2}}{5!} \dots$$

$$L\{\sin \sqrt{t}\} = L\{t^{1/2}\} - \frac{1}{3!} L\{t^{3/2}\} + \frac{1}{5!} L\{t^{5/2}\} \dots$$

$$= \frac{\Gamma(3/2)}{p^{3/2}} - \frac{1}{3!} \frac{\Gamma(5/2)}{p^{5/2}} + \frac{1}{5!} \frac{\Gamma(7/2)}{p^{7/2}} \dots$$

$$= \frac{1}{2} \frac{\sqrt{\pi}}{p^{3/2}} - \frac{1}{3!} \frac{3/2 \cdot 1/2 \sqrt{\pi}}{p^{5/2}} + \frac{1}{5!} \frac{5/2 \cdot 3/2 \cdot 1/2 \sqrt{\pi}}{p^{7/2}} \dots$$

$$L\{f(t)\} = F(p)$$

$$L\{e^{at} f(t)\} = F(p-a)$$

Now, this problem on shifting property; Laplace transform of $e^{-2t} \sin \sqrt{t}$ under root t , again we first we find out Laplace transform of $\sin \sqrt{t}$ and using shifting property, we will replace p by $p + 2$ because here a is minus two. So, what is Laplace transform of $\sin \sqrt{t}$ let us see. So, what is $\sin \theta$? $\sin \theta$ is $\theta - \theta^3/3! + \theta^5/5! - \dots$. What is $\sin \sqrt{t}$ under root t will be $t^{1/2} - t^{3/2}/3! + t^{5/2}/5! - \dots$.

Now, it is Laplace of $\sin \sqrt{t}$ will be nothing but Laplace transform of this entire expression, and by the linearity property we can split in term wise. So, this is nothing but Laplace transform of $t^{1/2}$ minus $1/3!$ Laplace transform of $t^{3/2}$ plus $1/5!$ Laplace transform of $t^{5/2}$. So, this is $t^{1/2}$ is $\Gamma(3/2)/p^{3/2}$. Using Laplace transform of t^{n-1} is $\Gamma(n)/p^n$, it is $\Gamma(5/2)/p^{5/2} + 1/5!$ because $\Gamma(n+1) = n \Gamma(n)$. So, $\Gamma(3/2)$ will be $1/2 \sqrt{\pi}$ and $\Gamma(5/2)$ is $3/2 \cdot 1/2 \sqrt{\pi}$. So, it is $1/2 \sqrt{\pi} / p^{3/2} - 1/3! \cdot 3/2 \cdot 1/2 \sqrt{\pi} / p^{5/2} + 1/5! \cdot 5/2 \cdot 3/2 \cdot 1/2 \sqrt{\pi} / p^{7/2} - \dots$

(Refer Slide Time: 20:15)

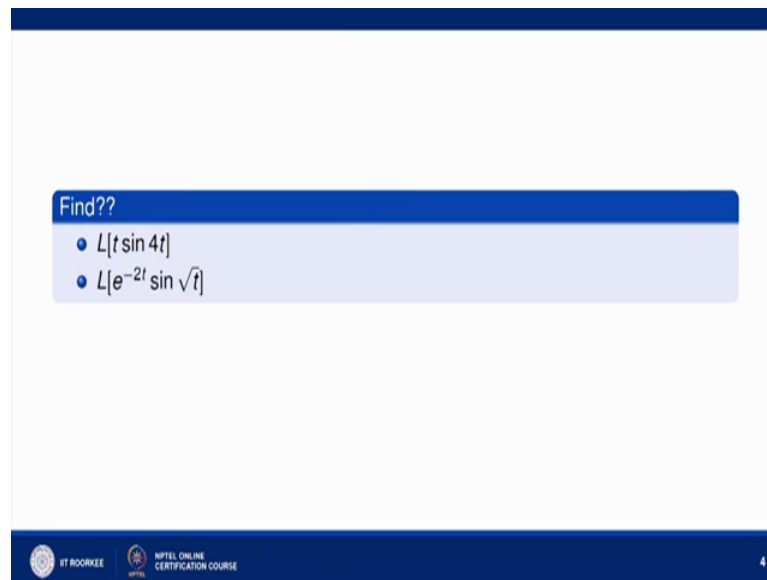

$$\begin{aligned}
 \mathcal{L}\{\sin \sqrt{t}\} &= \frac{1}{\sqrt{p}} \left[1 - \frac{(\frac{1}{2})^2}{p} + \frac{(\frac{1}{2})^4}{p^2} \dots \right] \\
 &= \frac{\sqrt{\pi}}{2 p^{3/2}} e^{-\frac{1}{4p}}
 \end{aligned}$$

$$\begin{aligned}
 \mathcal{L}\{f(t)\} &= F(p) \\
 \mathcal{L}\{e^{at} f(t)\} &= F(p-a)
 \end{aligned}$$

$$\begin{aligned}
 \mathcal{L}\{\sin \sqrt{t}\} &= \mathcal{L}\{t^{1/2}\} - \frac{1}{3} \mathcal{L}\{t^{3/2}\} + \frac{1}{25} \mathcal{L}\{t^{5/2}\} \dots \\
 &= \frac{\Gamma(3/2)}{p^{3/2}} - \frac{1}{3} \frac{\Gamma(5/2)}{p^{5/2}} + \frac{1}{25} \frac{\Gamma(7/2)}{p^{7/2}} \dots \\
 &= \frac{1}{2} \frac{\sqrt{\pi}}{p^{3/2}} - \frac{1}{3} \frac{3/2 \cdot 1/2 \sqrt{\pi}}{p^{5/2}} + \frac{1}{25} \frac{5/2 \cdot 3/2 \cdot 1/2 \sqrt{\pi}}{p^{7/2}} \dots
 \end{aligned}$$

So, what finally, we get. So, Laplace transform of sin under root t, this will be nothing but now you can take 1 by 2 under root pi upon this quantity common form of all the terms. So, this is 1 by 2 p k i power 3 by 2 into under root pi, inside bracket we get 1 minus. So, this is factorial 3 is 3 into 2 into 1, 3, 3 cancels out, under root 2 this we have taken common one. So, this is nothing but 1 by 2 square into p whole power upon 1 factorial because 1 2 comes from here 1 2 from here 1 2 is common, so it is 2 square. From here 5, into 5 cancels out, so it is nothing but plus 1 by 2 square p whole square upon factorial two this comes. When you simplify 5, 5 cancels out, 3 also cancels. So, we will get two square whole square upon factorial two and this is under root 2 p k power 3 by 2 and it is nothing but e k power minus 1 by 4 p, so that is the Laplace transform of sin under root t. So, this is F p.

(Refer Slide Time: 21:54)

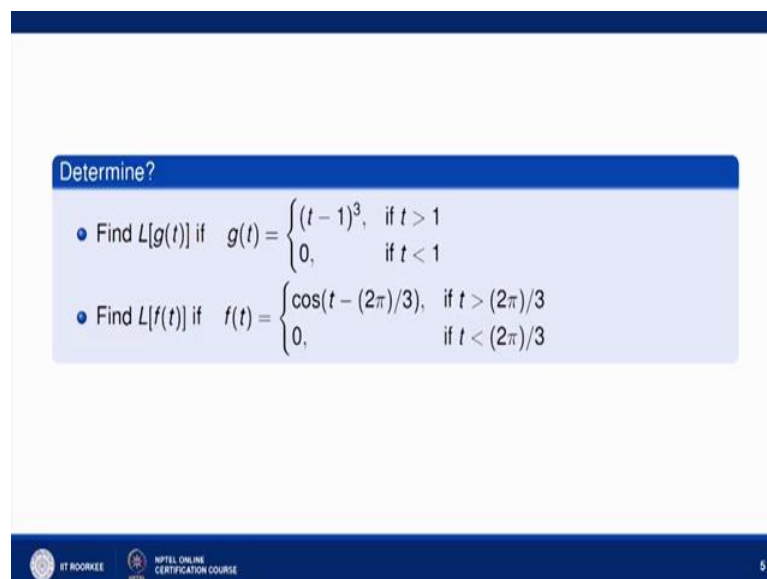

Find??

- $L[t \sin 4t]$
- $L[e^{-2t} \sin \sqrt{t}]$

IT ROOKIE NPTEL ONLINE CERTIFICATION COURSE 4

And for to find Laplace transform of $e^{-k} t$ you simply replace p by $p + k$ in this expression. This is $F(p)$, you replace p by $p + k$ you will get Laplace transform of this quantity.

(Refer Slide Time: 22:12)

Determine?

- Find $L[g(t)]$ if $g(t) = \begin{cases} (t-1)^3, & \text{if } t > 1 \\ 0, & \text{if } t < 1 \end{cases}$
- Find $L[f(t)]$ if $f(t) = \begin{cases} \cos(t - (2\pi)/3), & \text{if } t > (2\pi)/3 \\ 0, & \text{if } t < (2\pi)/3 \end{cases}$

IT ROOKIE NPTEL ONLINE CERTIFICATION COURSE 5

Again using second translation property, we can easily find out Laplace transform of $G(t)$ because if you compare with second shifting property, second translation, so Laplace transform of $f(t)$ is $F(p)$ then Laplace transform $G(t)$ is $e^{-k} F(p)$ by second translation property.

(Refer Slide Time: 22:44)

So, if we compare with this, here in the first problem, what is $G(t)$, what is $f(t) - a$. Now, $F(p - a)$, for the first problem $f(t)$ will be t^3 then only it is $t - a$, a is 1 whole cube. So, what is Laplace transform of $f(t)$? It is nothing but factorial 3 upon p power 4 that is 6 upon p power 4. Now, the Laplace transform this $G(t)$ will be nothing but $e^{-k p}$ minus a $e^{-k p}$ minus $a p$, a is 1 here, $a p$ into $F(p)$, and $F(p)$ is the this quantity. So, this is nothing but $e^{-k p}$ minus p $e^{-k p}$ minus p upon p power 4. So, this will be the Laplace transform of the first problem by the second translation property. Again for the second part you see that here $f(t)$ is this quantity, if you compare with this property, here $f(t)$ is the $f(t)$ given here in this term $f(t)$ here is $\cos t$. So, the Laplace of $\cos t$ is p upon $p^2 + 1$.

So, Laplace of this $f(t)$ will be nothing but using second translation property, Laplace of $f(t)$ will be nothing but $e^{-k p}$ minus $a p$, a is $2\pi/3$ $e^{-k p}$ minus $2\pi/3 p$ into p into Laplace of $\cos t$. Laplace of $\cos t$ is nothing but p upon $p^2 + 1$. So, this is how we can find out Laplace transform of this problems using second translation property. Now, the same shifting property also hold for inverse Laplace transforms inverse Laplace.

(Refer Slide Time: 24:58)

Slide 6 contains two sections. The first section, titled "First shifting property of Inverse Laplace transform", states: "If $L^{-1}[F(p)] = f(t)$, then $L^{-1}[F(p - a)] = e^{at}f(t)$ ". The second section, titled "Second shifting property of Inverse Laplace transform", states: "If $L^{-1}[F(p)] = f(t)$, then $L^{-1}[e^{-ap}F(p)] = \begin{cases} f(t - a), & \text{if } t > a \\ 0, & \text{if } t < a \end{cases}$ ". The slide footer includes the NPTEL logo, "IT ROOKIEE", "NPTEL ONLINE CERTIFICATION COURSE", and the number "6".

If inverse Laplace of $f(t)$ is $F(p)$, then inverse Laplace transform of p minus a is e^{kt} power a into $f(t)$. And the second shifting property states that if Laplace inverse of $F(p)$ is $f(t)$ then Laplace inverse of e^{kt} power minus a into $F(p)$ is nothing but $f(t - a)$ when t is greater than 0 when t less than a , this is by the shifting property itself.

(Refer Slide Time: 25:31)

Slide 7 is titled "Problems" and asks to "Find?". It lists three problems:

- $L^{-1}\left[\frac{3p + 2}{p^2 - 2p + 5}\right]$
- $L^{-1}\left[\frac{1}{\sqrt{4p + 5}}\right]$
- $L^{-1}\left[\frac{2p + 1}{(p - 1)(p^2 + 4p + 5)}\right]$

The slide footer includes the NPTEL logo, "IT ROOKIEE", "NPTEL ONLINE CERTIFICATION COURSE", and the number "7".

Now, based on this, let us try to solve these problems.

(Refer Slide Time: 25:35)

$$\begin{aligned}
 & \mathcal{L}^{-1} \left\{ \frac{3p+2}{p^2-2p+5} \right\} \\
 &= 3 \mathcal{L}^{-1} \left\{ \frac{p}{p^2-2p+5} \right\} + 2 \mathcal{L}^{-1} \left\{ \frac{1}{p^2-2p+5} \right\} \\
 &= 3 \mathcal{L}^{-1} \left\{ \frac{p-1+1}{(p-1)^2+4} \right\} + 2 \mathcal{L}^{-1} \left\{ \frac{1}{(p-1)^2+4} \right\} \\
 &= 3 \mathcal{L}^{-1} \left\{ \frac{p-1}{(p-1)^2+4} \right\} + 5 \mathcal{L}^{-1} \left\{ \frac{1}{(p-1)^2+4} \right\} \\
 &= 3 e^t \mathcal{L}^{-1} \left\{ \frac{p}{p^2+4} \right\} + 5 e^t \mathcal{L}^{-1} \left\{ \frac{1}{p^2+4} \right\} \\
 &= 3 e^t \left(\cos 2t + \frac{5}{2} e^t \sin 2t \right)
 \end{aligned}$$

$\mathcal{L}\{f(t)\} = F(p)$
 $\mathcal{L}\{e^{at} f(t)\} = F(p-a)$
 $\mathcal{L}^{-1}\{F(p)\} = f(t)$
 Then
 $\mathcal{L}^{-1}\{F(p-a)\} = e^{at} f(t)$

So, the first problem is Laplace of 3 p upon plus 2 upon p square minus 2 p plus 5. So, Laplace of this is 3 times p upon p square minus 2 p plus 5 plus 2 times Laplace inverse it is Laplace inverse yeah. So, it is Laplace inverse of 1 upon p square minus 2 p plus 5. So, it is 3 Laplace inverse of p upon it is p minus 1 whole square plus 4, it is 2 times Laplace inverse of 1 upon p minus 1 whole square plus 4. Now, here p minus 1, so you subtract 1 and add 1 here, so this is 3 Laplace inverse of p minus 1 upon p minus 1 whole square plus 4 and 3 into 1 upon this quantity plus 2 into 1 upon this quantity will be 5 times Laplace inverse of 1 upon p minus 1 whole square plus 4.

Now, we know that Laplace inverse of F p is f t, if this happens then Laplace inverse of F p is minus a will be nothing but e k power a t into f t, by the inverse of property shifting property. Now, here if you use this definition F p minus a, here a is 1. So, it is nothing but 3 e k power a t, a is 1, so 3 into e k power t. And f t and f t will be Laplace inverse of F p. So, it will be Laplace inverse of p upon p square plus 4. You replace you replace p plus 1, so it will be p upon p square plus 4. So, that will be Laplace inverse of this quantity. Again plus you replace p by this property is nothing but 5 into e k power t Laplace inverse of 1 upon p square plus 4. So, this is nothing but 3 into e k power t this is cos 2 t plus 5 into e k power t, you divide multiply into 2. So, it is 2 upon this sin 2 t, so that will be the Laplace inverse of this expression that will be Laplace transform of this expression.

(Refer Slide Time: 28:55)

$$\mathcal{L}^{-1}\left\{\frac{1}{\sqrt{4p+5}}\right\}$$

$$= \frac{1}{2} \mathcal{L}^{-1}\left\{\frac{1}{\sqrt{p+5/4}}\right\}$$

$$= \frac{1}{2} e^{-5/4 t} \mathcal{L}^{-1}\left\{\frac{1}{\sqrt{p}}\right\}$$

$$= \frac{1}{2} e^{-5/4 t} \frac{t^{-1/2}}{\Gamma(1/2)}$$

$$= \frac{1}{2} e^{-5/4 t} \frac{1}{\sqrt{\pi t}}$$

$$\mathcal{L}\{f(t)\} = F(p)$$

$$\mathcal{L}\{e^{at} f(t)\} = F(p-a)$$

$$\mathcal{L}^{-1}\{F(p-a)\} = e^{at} f(t)$$

Then

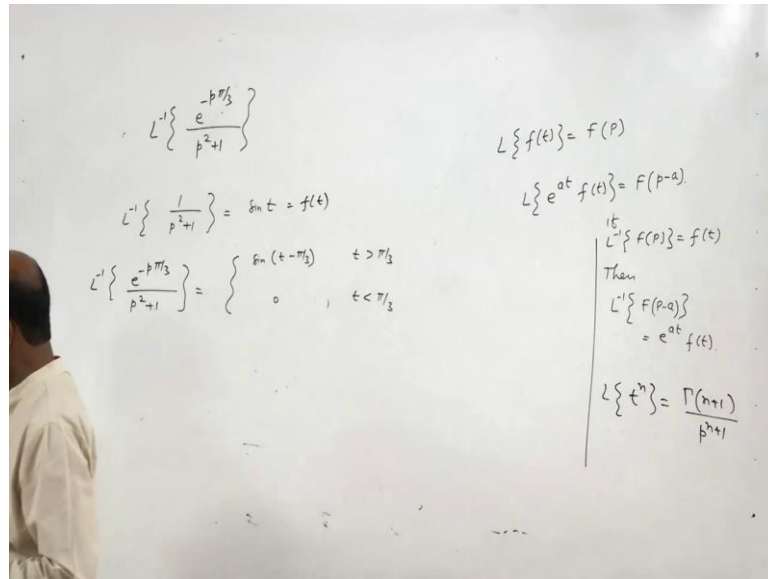

$$\mathcal{L}^{-1}\{F(p-a)\} = e^{at} f(t)$$

$$\mathcal{L}\{t^n\} = \frac{\Gamma(n+1)}{p^{n+1}}$$

Similarly, when you apply the same thing in second problem Laplace inverse of this, so it is $2p + 1$, it is 1 upon under root $4p + 5$, second problem. So, you take 4 common first. So, it is 1 by 2 Laplace inverse of 1 upon under root $p + 5$ by 4 . Use this shifting property. Now here a is minus 5 by 4 , so it will be 1 by 2 $e^{-5/4 t}$ Laplace inverse of 1 by under root p by the shifting property or for inverse Laplace transforms. And this is again is equal to 1 by 2 $e^{-5/4 t}$, we know that now for to find Laplace inverse of this expression, we know that Laplace transform of t^k power n is nothing but $\Gamma(n+1)$ upon p^{n+1} .

So, Laplace inverse of 1 upon p^k power $n + 1$ is nothing but t^k power n upon $\Gamma(n + 1)$. So, replace n by n by minus half. So, it is t^k power minus half upon $\Gamma(1/2)$, so that is nothing but 1 by 2 $e^{-5/4 t}$ $t^{5/4}$ into 1 by under root π into t so that will be the Laplace inverse of this expression. Now, to solve the last problem we can use partial fractions. This we use partial fraction to simply this and then we apply the shifting property to find out the Laplace inverse of this expression. The third problem we can solve.

(Refer Slide Time: 31:03)

Now to find out Laplace inverse of these two problems again we will use second shifting second translation property for inverse Laplace transforms. First we will find Laplace inverse of here we have problem e^{-k} upon $p^2 + 1$. So, first find Laplace inverse of 1 upon $p^2 + 1$, so that is nothing but $\sin t$. Now, using second translation property Laplace inverse of e^{-k} upon $p^2 + 1$ will be nothing but $\sin t - k$, when $t > k$, and 0 when $t < k$. And this is because by the second property by the second translation property we have seen that Laplace inverse of this quantity is nothing but $f(t - a)$ when $t > a$ and 0 when $t < a$.

(Refer Slide Time: 32:10)

First shifting property of Inverse Laplace transform

If $L^{-1}[F(p)] = f(t)$, then $L^{-1}[F(p-a)] = e^{at}f(t)$

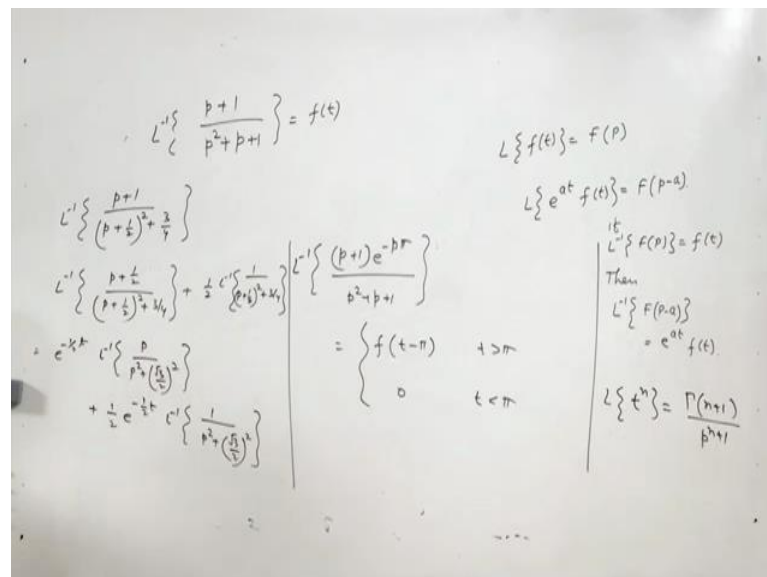

Second shifting property of Inverse Laplace transform

If $L^{-1}[F(p)] = f(t)$, then $L^{-1}[e^{-ap}F(p)] = \begin{cases} f(t-a), & \text{if } t > a \\ 0, & \text{if } t < a \end{cases}$

6

Here a is minus pi by 3. So, you replace t minus pi by 3 in this f t, this is f t, this is f t. Now, for second the last problem again we will first find Laplace inverse of p plus 1 upon 1 p square p plus 1 and then using second shifting property, we will find Laplace inverse of entire expression.

(Refer Slide Time: 32:46)

$$L^{-1}\left\{\frac{p+1}{p^2+p+1}\right\} = f(t)$$

$$L^{-1}\left\{\frac{p+1}{(p+\frac{1}{2})^2 + \frac{3}{4}}\right\}$$

$$L^{-1}\left\{\frac{p+\frac{1}{2}}{(p+\frac{1}{2})^2 + \frac{3}{4}}\right\} + \frac{1}{2}L^{-1}\left\{\frac{1}{(p+\frac{1}{2})^2 + \frac{3}{4}}\right\}$$

$$= e^{-\frac{1}{2}t} L^{-1}\left\{\frac{p}{p^2 + (\frac{\sqrt{3}}{2})^2}\right\} + \frac{1}{2}e^{-\frac{1}{2}t} L^{-1}\left\{\frac{1}{p^2 + (\frac{\sqrt{3}}{2})^2}\right\}$$

$$= \begin{cases} f(t-\pi) & t > \pi \\ 0 & t < \pi \end{cases}$$

$$L\{f(t)\} = F(p)$$

$$L\{e^{at}f(t)\} = F(p-a)$$

$$L^{-1}\{F(p-a)\} = f(t)$$

Then

$$L^{-1}\{F(p-a)\} = e^{at}f(t)$$

$$L\{t^n\} = \frac{\Gamma(n+1)}{p^{n+1}}$$

So, what is, so first we will find Laplace inverse of this expression p plus 1 upon p square plus p plus 1. We will call it f t. And then for this entire expression, we replace t by t minus pi the Laplace inverse of this will be nothing but minus p pi, this will be

nothing but $f(t) = t - \pi$ when $t > \pi$ and 0 when $t < \pi$. So, this we can obtain by using second property. So, Laplace of inverse of this, we can find making perfect square in the denominator.

Let us to make it this is $p + \frac{1}{2}$ whole square plus $\frac{3}{4}$, and this is nothing but Laplace inverse of $p + \frac{1}{2}$ upon $p + \frac{1}{2}$ whole square plus $\frac{3}{4}$ plus $\frac{1}{2}$ Laplace inverse of 1 upon $p + \frac{1}{2}$ whole square plus $\frac{3}{4}$. And it is e^{-k} power minus $\frac{1}{2}t$ by using shifting property $p + \frac{1}{2}$ plus $\frac{1}{2}$ is 1. And it is $\frac{1}{2}$ square plus yeah it is e^{-k} power e^{-k} power $a t$ a is minus half minus half is Laplace inverse of p upon $p^2 + \text{under root } \frac{3}{2} \text{ whole square} + \frac{1}{2}$ e^{-k} power minus $\frac{1}{2}t$ Laplace inverse of 1 upon $p^2 + \text{under root } \frac{3}{2} \text{ whole square}$. Now, this we can find out this is nothing but $\cos a t$, a is under root $\frac{3}{2}$, you multiply and divide by this quantity here, this will be nothing but $\sin a t$ and $\sin a$ is under root $\frac{3}{2}$. So, that will be $f(t)$ and you replace you substitute $f(t)$ here, so you will get Laplace inverse of this expression.

So, thank you very much.
