Lecture – 29
Properties of Laplace transforms-IV

Hello everyone, we will be studying about properties of Laplace transforms. In the last three lectures we have seen some of the properties of Laplace transform and the questions related to that. Now this is the last lecture on properties of Laplace transform. So, the next property is, if Laplace transform of $f(t)$ is $F(p)$, then Laplace transform of $t^n f(t)$ is nothing but minus 1 power n , n th derivative of $F(p)$, so how can we prove this property.

(Refer Slide Time: 00:44)

Laplace transform of functions multiplied by t^n

If $L[f(t)] = F(p)$, then

$$L[t^n f(t)] = (-1)^n \frac{d^n}{dp^n} F(p) = (-1)^n F^{(n)}(p).$$

IFT ROORKEE NITRR ONLINE CERTIFICATION COURSE 2

So, Laplace transform of $t^n f(t)$ is nothing, but minus 1 power n n th derivative of $F(p)$. So, what is $F(p)$ here? Laplace of $f(t)$.

(Refer Slide Time: 00:58)

$$\mathcal{L}\{t^n f(t)\} = (-1)^n \frac{d^n}{dp^n} F(p)$$

$$\text{for } n=1, \mathcal{L}\{t f(t)\} = -\frac{d}{dp} F(p) = -F'(p)$$

$$F'(p) = \frac{d}{dp} F(p) = \frac{d}{dp} \int_0^{\infty} e^{-pt} f(t) dt$$

$$= \int_0^{\infty} \frac{\partial}{\partial p} (e^{-pt} f(t)) dt$$

$$= \int_0^{\infty} -t e^{-pt} f(t) dt$$

$$= -\mathcal{L}\{t f(t)\}$$

So, again we will use the method of induction to prove this result. So, let us prove for n equal to 1 first, for n equal to 1. So, Laplace transform of $t f(t)$ is nothing, but negative of d by dp of $F(p)$, or is we call it as minus F dash p . So, how to prove this? So, what is F dash p ? F dash p is nothing, but d by dp of $F(p)$ and $F(p)$ is nothing, but Laplace transform of $f(t)$ which is 0 to infinity $e^{-pt} f(t) dt$. this is because $F(p)$ is nothing, but Laplace transform of $f(t)$. So, by Leibniz rules, we can easily write this as 0 to infinity d by dp of $e^{-pt} f(t) dt$.

So, this is 0 to infinity, partial derivative with respect to p of this expression will be nothing, but minus $t e^{-pt} f(t) dt$, and it is nothing, but negative of Laplace of $t f(t)$, because Laplace of $t f(t)$ is what, 0 to infinity $t f(t) e^{-pt} dt$ which is this expression. So, hence Laplace of $t f(t)$ is nothing, but negative of F dash p . So, we obtain this result for n equal to 1. Now assume that result hold for n equal to say k , and we will try to prove that is result also hold for n equal to k plus 1. So, assume that this result holds for n equal to k .

(Refer Slide Time: 03:10)

$$\mathcal{L}\{t^n f(t)\} = (-1)^n \frac{d^n}{dp^n} F(p)$$

Assume that this result holds for $n = k$.

For $n = k+1$

$$\mathcal{L}\{t^{k+1} f(t)\} = (-1)^{k+1} \frac{d^{k+1}}{dp^{k+1}} F(p)$$

$$(-1)^{k+1} \frac{d^{k+1}}{dp^{k+1}} F(p) = (-1)^{k+1} \frac{d}{dp} \left[\frac{d^k}{dp^k} F(p) \right]$$

$$= (-1)^{k+1} \frac{d}{dp} \left[(-1)^k \mathcal{L}\{t^k f(t)\} \right]$$

$$= (-1)^{2k+1} \frac{d}{dp} \int_0^{\infty} t^k f(t) e^{-pt} dt$$

$$= (-1)^{2k+1} \int_0^{\infty} -t^k f(t) e^{-pt} dt$$

$$= (-1)^{2k+2} \int_0^{\infty} t^k f(t) e^{-pt} dt$$

$$= \mathcal{L}\{t^{k+1} f(t)\}$$

So, we have to show that this result also hold for n equal to k plus 1. So, for n equal to k plus 1, Laplace of n k plus 1 f t is equals to minus 1 k power k plus 1 and k plus 1th derivative of p F p , this to show. So, let us take the right hand side, right hand side is minus 1 k power 1 k plus 1 k plus 1th derivative of F p , which is nothing, but minus 1 k power k plus 1 d by dp of f of k th derivative with respect to p of F p , and this we have already assumed that the result hold for n equal to k . So, since the result hold for n equals to k . So, this value is nothing, but minus 1 k power k plus 1 d by dp of, from here you substitute n equal to k . So, this will be nothing, but minus 1 k power k Laplace of t k power k f t .

So, this is minus 1 k power 2 k plus 1, and this is d by dp of 0 to infinity t k power k f t e k power minus p t dt , because Laplace of t k power k f t is nothing, but t k power k f t e k power minus p t dt integral 0 to infinity. Again use Leibniz rules. So, when this go inside this will be del by del p . So, this expression will be nothing, but is equal to minus 1 k power 2 k plus 1, and del by del p of this expression will be 0 to infinity minus d times into t k power k f t e k power minus p t dt . So, this is nothing, but minus 1 k power 2 k plus 2 0 to infinity t k power k plus 1 f t e k power minus p t dt , and this minus having the even power, this will be plus 1 and this is nothing, but Laplace transform of this expression, Laplace transform of t k power k plus 1 f t .

(Refer Slide Time: 06:42)

Determine?

- $L\{t^2 \cos 2t\}$
- $L\{te^{-2t} \sin 4t\}$

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

So, hence this result also hold for n equal to k plus 1. So, hence hold for all n. So, hence this result, hence we have this result. Now let us try to solve some problems based on this result, whenever we have in some problems involving multiplication with t, and we have to find Laplace of that. So, we will always use this property of Laplace transforms, whenever we have multiplication of t with f t, of any positive integer power we will use Laplace of t k power in f t, I mean this expression.

(Refer Slide Time: 07:12)

$$\begin{aligned} L\{t^n f(t)\} &= (-1)^n \frac{d^n}{dp^n} F(p) \\ L\{t^2 \cos 2t\} &= (-1)^2 \frac{d^2}{dp^2} F(p) \quad , \quad f(p) = L\{\cos 2t\} \\ &= \frac{d^2}{dp^2} \left(\frac{p}{p^2+4} \right) \\ &= \frac{d}{dp} \left(\frac{(p^2+4) - p(2p)}{(p^2+4)^2} \right) = \frac{d}{dp} \left(\frac{4-p^2}{(p^2+4)^2} \right) \\ &= \frac{(p^2+4)^2 (-2p) - (4-p^2) 2(p^2+4)(2p)}{(p^2+4)^4} \end{aligned}$$

So, suppose you want to find Laplace transform of $t^2 \cos 2t$. So, what is $f(t)$ here, it is $\cos 2t$ what is n , n is 2. So, this is this will be nothing, but minus 1 k power 2, second derivative of $F(p)$ and what is $F(p)$. $F(p)$ is Laplace transform of $f(t)$, $f(t)$ here is $\cos 2t$.

So, $f(t)$ will be Laplace transform of $\cos 2t$ which is nothing, but p upon $p^2 + 4$. So, it is d^2 by dp^2 , I mean second derivative of p upon $p^2 + 4$. So, it is d by dp of. First derivative is numerator derivative a denominator minus denominator derivative numerator upon denominator whole square, this is by quotient property of derivatives. So, this is d by dp of this is $4 - p^2$ upon $(p^2 + 4)^2$. So, again we will find derivative of this $F(p)$. So, what is derivative of this $F(p)$? So, derivative of this $F(p)$ will be nothing, but again the denominator, derivative of numerator minus numerator derivative of denominator and denominator of whole square.

So, we will simplify this and we will get the final answer for the Laplace transform of $t^2 \cos 2t$. Now let us try to solve the second problem, in which we have to Laplace transform of $t e^{-2t} \sin 4t$. So, here we have only t that is a 1 power of t . So, we have to differentiate only 1 time.

(Refer Slide Time: 09:46)

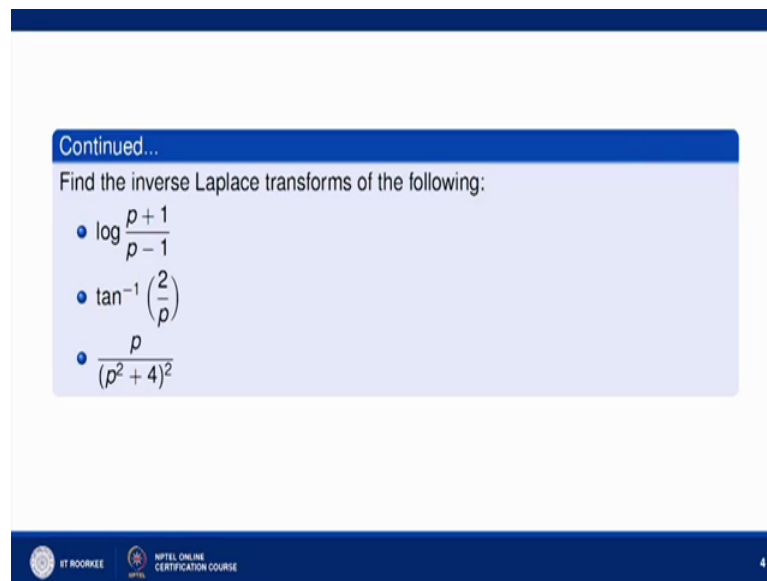

$$\begin{aligned}
 \mathcal{L}\{t^n f(t)\} &= (-1)^n \frac{d^n}{dp^n} F(p) \\
 \mathcal{L}\{t e^{-2t} \sin 4t\} &= (-1)^1 \frac{d}{dp} \left(\frac{4}{(p+2)^2 + 16} \right) \\
 &= \frac{4}{((p+2)^2 + 16)^2} \\
 &= \frac{8(p+2)}{(p^2 + 4p + 20)^2}
 \end{aligned}$$

So, that is Laplace transform of $t e^{-2t} \sin 4t$. This will be nothing, but minus 1 k power 1 d by dp of. Now Laplace transform of this expression this is $f(t)$. So, Laplace transform of $\sin 4t$ is 4 upon $p^2 + 16$, and using shifting property we

replace p by $p + 2$. So, it will be nothing, but 4 upon $p + 2$ whole square plus 16 . This is $f(t)$, and Laplace transform of $f(t)$ is $F(p)$.

So, Laplace transform of this $f(t)$ is this. So, you now you can differentiate here. So, it is 1 by t square and t again that is $2p + 2$. So, it is nothing, but $8p + 2$ upon p square plus $4p + 20$ whole square. So, this will be the Laplace inverse of this expression.

(Refer Slide Time: 11:10)

Continued...

Find the inverse Laplace transforms of the following:

- $\log \frac{p+1}{p-1}$
- $\tan^{-1} \left(\frac{2}{p} \right)$
- $\frac{p}{(p^2+4)^2}$

IT ROOKIE NPTEL ONLINE CERTIFICATION COURSE 4

Now, let us try to find out Laplace inverse of these expression using this property. So, whenever we have \log \tan inverse \cot inverse, we always use Laplace transform of $t f(t)$ equal to minus d by dp of $F(p)$ property, this property. So, let us try to solve few problems based on this.

(Refer Slide Time: 11:35)

$$\mathcal{L}\{t^n f(t)\} = (-1)^n \frac{d^n}{dp^n} F(p)$$

$$F(p) = \log\left(\frac{p+1}{p-1}\right) = \log(p+1) - \log(p-1)$$

$$F'(p) = \frac{1}{p+1} - \frac{1}{p-1}$$

$$\mathcal{L}\{F'(p)\} = e^{-t} - e^t$$

$$\Rightarrow -t f(t) = e^{-t} - e^t$$

$$\Rightarrow f(t) = \frac{e^{-t} - e^t}{-t} = \mathcal{L}^{-1}\{F'(p)\}$$

$$\mathcal{L}\{t f(t)\} = -F'(p)$$

$$\Rightarrow t f(t) = -\mathcal{L}^{-1}\{F'(p)\}$$

So, this is $F(p)$, $F(p)$ is \log of p plus 1 upon p minus 1. So, if we have to find out Laplace inverse of this $F(p)$. So, what is $F'(p)$? $F'(p)$ will be this is nothing, but \log of p plus 1 minus \log of p minus 1. So, this is $\frac{1}{p+1} - \frac{1}{p-1}$. Now take Laplace inverse both the sides. So, Laplace inverse of $F'(p)$ is nothing, but Laplace inverse of $\frac{1}{p+1}$, it is e^{-t} minus e^t . Now Laplace inverse of $t f(t)$ is what, is minus $F'(p)$ minus from this property if you substitute n equal to 1. Here $F(p)$ is Laplace inverse of this $f(t)$.

So, So, from here we got $t f(t)$ is nothing, but negative of Laplace inverse of $F'(p)$. So, Laplace inverse of $F'(p)$ will be nothing, but minus $t f(t)$ from that expression is equal to $e^{-t} - e^t$ and this $f(t)$ is nothing, but Laplace inverse of $F(p)$. So, therefore, this implies $f(t)$ will be nothing, but $e^{-t} - e^t$ upon $-t$ and this is nothing, but Laplace inverse of $f(t)$ and $F(p)$ is this. So, hence the Laplace inverse of \log p plus 1 upon p minus 1 is $e^{-t} - e^t$ by $-t$.

Now again the second problem. Now $F(p)$ here is what? $F(p)$ here the second problem is $\tan^{-1} \frac{2}{p}$.

(Refer Slide Time: 13:42)

$$\mathcal{L}\{t^n f(t)\} = (-1)^n \frac{d^n}{dp^n} F(p)$$

$$F(p) = \tan^{-1}\left(\frac{2}{p}\right)$$

$$F'(p) = \frac{1}{1 + \left(\frac{2}{p}\right)^2} \left(-\frac{2}{p^2}\right)$$

$$= \frac{-2}{p^2 + 4}$$

$$\mathcal{L}^{-1}\{F'(p)\} = -\mathcal{L}^{-1}\left\{\frac{2}{p^2 + 4}\right\} = -\sin 2t$$

$$-t f(t) = -\sin 2t$$

$$\Rightarrow f(t) = \frac{\sin 2t}{t}$$

$$\mathcal{L}\{t f(t)\} = -F'(p)$$

$$\Rightarrow t f(t) = -\mathcal{L}^{-1}\{F'(p)\}$$

So, what is $F'(p)$ $\frac{1}{1 + \frac{2}{p^2}}$ $\tan^{-1} \frac{2}{p}$ $\frac{d}{dp}$ of $\tan^{-1} \frac{2}{p}$ again. So, it is nothing, but $-\frac{2}{p^2 + 4}$. Now take Laplace inverse both sides. So, Laplace inverse of $F'(p)$ will be nothing, but minus Laplace inverse of $\frac{2}{p^2 + 4}$, and it is nothing, but minus $\sin 2t$. and Laplace inverse of $F'(p)$ from that expression is nothing, but minus $t f(t)$ which is equals to minus $\sin 2t$. So, this implies $t f(t)$ is nothing, but $\sin 2t$ by t and this $t f(t)$ is nothing, but Laplace inverse of this $F'(p)$. So, these type of problems can be solved using this expression, this expression.

Now the third problem it is $F(p)$ here is $\frac{p}{p^2 + 4}$ whole square.

(Refer Slide Time: 15:11)

$$\mathcal{L}\{t^n f(t)\} = (-1)^n \frac{d^n}{dp^n} F(p)$$

$$F(p) = \frac{p}{(p^2+4)^2}$$

$$\mathcal{L}^{-1}\left\{\frac{p}{(p^2+4)^2}\right\} = \frac{1}{4} t \sin 2t$$

$$\text{Let } G(p) = \frac{1}{p^2+4} \quad \mathcal{L}^{-1}\{G(p)\} = \frac{1}{2} \sin 2t = g(t)$$

$$G'(p) = -\frac{1}{(p^2+4)^2} \cdot 2p = -\frac{2p}{(p^2+4)^2}$$

$$\mathcal{L}^{-1}\{G'(p)\} = -2 \mathcal{L}^{-1}\left\{\frac{p}{(p^2+4)^2}\right\}$$

$$-t g(t) = -2 \mathcal{L}^{-1}\left\{\frac{p}{(p^2+4)^2}\right\}$$

$$-\frac{1}{2} t \sin 2t = -2 \mathcal{L}^{-1}\left\{\frac{p}{(p^2+4)^2}\right\}$$

$$\mathcal{L}\{t f(t)\} = -F'(p)$$

$$\Rightarrow t f(t) = -\mathcal{L}^{-1}\{F'(p)\}$$

So, let us take, let $G(p)$ is equals to 1 upon p square plus 4 . Of course, Laplace inverse of $G(p)$ is what? You divide and multiply by 2 . So, it is 1 by $2 \sin 2t$. Now you differentiate both side $G'(p)$ will be nothing, but it is 1 by t minus 1 by d square and derivative of t again $2p$. So, that is nothing, but minus $2p$ upon p upon p square plus 4 whole square. So, Laplace inverse, take Laplace inverse both the sides $G'(p)$ will be nothing, but minus 2 times Laplace inverse of p upon p square plus 4 whole square.

Now, this Laplace inverse is to find out. Now Laplace inverse of $G'(p)$ using this property is nothing, but negative of $t g(t)$, where $g(t)$ is Laplace of $G(p)$ and Laplace of $t g(t)$ is $G'(p)$. So, Laplace inverse of $G(p)$ is $g(t)$ which is given by this. So, minus 1 by $2 t \sin 2t$, is equals to minus 2 Laplace inverse of this expression. So, Laplace inverse of this expression will be nothing, but 1 by $4 t \sin t$. So, Laplace inverse of p upon p square plus 4 whole square will be nothing, but 1 by $4 t \sin 2t$. So, this is how we can find out Laplace inverse of this expression.

(Refer Slide Time: 17:59)

Laplace transforms of Integrals

If $L\{f(t)\} = F(p)$, then

$$L\left[\int_0^t f(u)du\right] = \frac{1}{p}F(p)$$

Inverse Laplace transforms of integrals

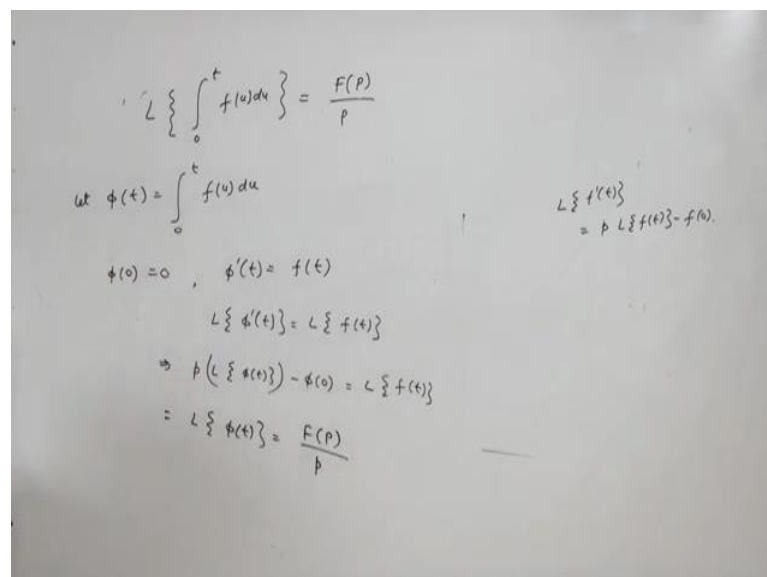

If $L^{-1}\{F(p)\} = f(t)$ then

$$L^{-1}\left[\frac{F(p)}{p}\right] = \int_0^t f(u)du$$

NPTEL ONLINE CERTIFICATION COURSE
5

Now, let us see some more properties of Laplace transforms, this is Laplace transform of integrals. So, if Laplace transform of $f(t)$ is $F(p)$ then Laplace transform of $\int_0^t f(u)du$ is nothing, but $F(p)$ by p . So, this property is mostly use to find Laplace inverse of $F(p)$ by p , whenever we have Laplace inverse of $F(p)$ by p types; that is division by p then this property is more useful, since Laplace inverse of $F(p)$ by p is given by $\int_0^t f(u)du$.

(Refer Slide Time: 18:28)

$$L\left\{\int_0^t f(u)du\right\} = \frac{F(p)}{p}$$

Let $\phi(t) = \int_0^t f(u)du$

$\phi(0) = 0$, $\phi'(t) = f(t)$

$L\{\phi'(t)\} = L\{f(t)\}$

$\Rightarrow p(L\{\phi(t)\}) - \phi(0) = L\{f(t)\}$

$= L\{\phi(t)\} = \frac{F(p)}{p}$

$L\{f'(t)\} = pL\{f(t)\} - f(0)$

So, how to prove this property, Laplace transform of $\int_0^t f(u)du$ is nothing but $F(p)$ by p , and this $F(p)$ is nothing, but Laplace transform of this f . So, proof is simple you let $\phi(t)$ is

equals to $\int_0^t f(u) du$. So, what will be $\phi(0)$? Is of course, 0, because when you take t equal to 0 value will be 0, and what is $\phi'(t)$? So, you have to differentiate with respect to t . So, you have to apply Leibniz theorem here. So, when you apply Leibniz theorem, it is nothing, but $f(t)$. now here you take Laplace both the sides. So, Laplace transform of $\phi'(t)$ will be nothing but Laplace transform of $f(t)$, but Laplace transform of $\phi'(t)$, Laplace transform of $\phi'(t)$ is nothing, but p into Laplace transform of $\phi(t)$ minus $\phi(0)$, is equals to Laplace transform of $\phi'(t)$, because Laplace transform of $f'(t)$ we have already proved is nothing, but p into Laplace transform of $f(t)$ minus $f(0)$. So, Laplace transform of $\phi'(t)$ is nothing but p into Laplace transform of $\phi(t)$ minus $\phi(0)$. So, p into Laplace transform of $\phi(t)$ minus $\phi(0)$ is equals to Laplace of $f(t)$ because these 2 are equal.

Now $\phi(0)$ is 0. So, Laplace transform of $\phi(t)$ is nothing, but Laplace transform of $f(t)$. We are taking as F/p . So, it is F/p and this p will come in the denominator. So, divided by p and $\phi(t)$ is nothing, but this expression. So, Laplace transform of integrals $\int_0^t f(u) du$ is nothing, but F/p by p , where F/p is Laplace transform of $f(t)$. So, whenever we have division by p in the Laplace inverse, then we mostly use this property.

(Refer Slide Time: 20:58)

The slide contains the following text:

Evaluate

- $L\left(\int_0^t te^t \sin^2 t dt\right)$
- $L\left[t \int_0^t \frac{e^{-t} \sin t}{t} dt\right]$
- $L\left[\int_0^t \int_0^t (t \sin t) dt dt\right]$

At the bottom of the slide, there are logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and the number 6 in the bottom right corner.

Let us see some problems based on this. Now $\int_0^t \int_0^t e^{kt} \sin^2 t$, this simple problem, so $\int_0^t e^{kt} \sin^2 t$. Suppose we have to find out Laplace of, we have to find out Laplace of this.

(Refer Slide Time: 21:10)

$$\mathcal{L}\left(\int_0^t e^t \sin^2 t \, dt\right) = \frac{\mathcal{L}\{t e^t \sin^2 t\}}{p}$$

$$\mathcal{L}\{t e^t \sin^2 t\}$$

$$\mathcal{L}\{\sin^2 t\} = \mathcal{L}\left\{\frac{1 - \cos 2t}{2}\right\}$$

$$= \frac{1}{2p} - \frac{1}{2} \frac{p}{p^2 + 4}$$

$$\mathcal{L}\{e^t \sin^2 t\} = \frac{1}{2(p-1)} - \frac{p-1}{2[(p-1)^2 + 4]}$$

$$\mathcal{L}\{t e^t \sin^2 t\} = -\frac{d}{dp} \left[\frac{1}{2(p-1)} - \frac{p-1}{2[(p-1)^2 + 4]} \right]$$

So, we have to find out Laplace of this. So, how to find Laplace of this? Laplace of this, for Laplace of this first find this is $f \cdot t$. So, by this property this is nothing, but $F(p)$ by p that is Laplace of $t e^{kt}$ power t into $\sin^2 t$ by p , because this is $f \cdot t$. So, by using this property, by using this property Laplace of $f \cdot t$ will be here divided by p . So, this is why we have p here, and this Laplace we can easily find out, because Laplace of $t e^{kt}$ power t $\sin^2 t$. First find Laplace of $t \sin^2 t$, apply a shifting property of e^{kt} power t , and for t we already know that Laplace of $t f(t)$ is minus of $F'(p)$. So, it is nothing, but. So, what is Laplace of $\sin^2 t$ first? Laplace of $1 - \cos 2t$ by 2 . So, it is $\frac{1}{2p} - \frac{1}{2} \frac{p}{p^2 + 4}$, and Laplace of e^{kt} power $t \sin^2 t$ will be nothing, but you replace p by $p - 1$ using shifting property, so $\frac{1}{2(p-1)} - \frac{p-1}{2[(p-1)^2 + 4]}$ minus $p - 1$ upon 2 into $p - 1$ whole square plus 4 .

And for Laplace transform of $t e^{kt}$ power $t \sin^2 t$, you simply take minus of d by dp of this f , this f is, you take d by dp of this f . So, you can differentiate it respect to p and you can find out the final answer. So, that divided by p will be the Laplace transform of this expression. So, in the first expression it is, here we have a Laplace transform of this. Now, how to find out Laplace transform of this expression? So, that is also we can find.

(Refer Slide Time: 24:33)

The image shows handwritten mathematical derivations for Laplace transforms. The main result at the top is:

$$\mathcal{L} \left\{ \int_0^t \frac{e^{-t} \sin t}{t} dt \right\} = \frac{\frac{\pi}{2} - \tan^{-1}(p+1)}{p}$$

Below this, several other transforms are derived:

- $\mathcal{L} \{ e^{-t} \sin t \} = \frac{1}{(p+1)^2 + 1}$
- $\mathcal{L} \{ t e^t \sin^2 t \}$ (written but not fully derived)
- $\mathcal{L} \left\{ \frac{e^{-t} \sin t}{t} \right\} = \int_p^\infty \left(\frac{1}{(u+1)^2 + 1} \right) du$
- $\mathcal{L} \{ \sin^2 t \} = \mathcal{L} \left\{ \frac{1 - \cos 2t}{2} \right\} = \frac{1}{2p} - \frac{1}{2} \frac{p}{p^2 + 4}$
- $\mathcal{L} \{ e^t \sin^2 t \} = \frac{1}{2(p-1)} - \frac{p-1}{2[(p-1)^2 + 4]}$
- $\mathcal{L} \{ t e^t \sin^2 t \} = -\frac{d}{dp} \left[\frac{1}{2(p-1)} - \frac{p-1}{2[(p-1)^2 + 4]} \right]$

The integral derivation uses the substitution $u+1 = z$ and $du = dz$, leading to $\int_{p+1}^\infty \frac{1}{z^2 + 1} dz = \left[\tan^{-1} z \right]_{p+1}^\infty = \frac{\pi}{2} - \tan^{-1}(p+1)$.

So, first we will find Laplace transform of an integral part and t into $f(t)$ will be we use minus of $F(p)$; that property. So, how to find Laplace of integral 0 to t e^{kt} power minus $t \sin t$ by t , so it involves so many things. First we have to find out Laplace of $\sin t$ $\sin t$ is 1 upon p square plus 1 . For e^{kt} power minus t we have to apply shifting property you replace p by p minus, you replace p by a p plus 1 because a here is minus 1 .

So, Laplace of e^{kt} power minus $t \sin t$ will be nothing, but 1 upon p plus 1 whole square plus 1 , because Laplace of e^{kt} power a t $f(t)$ is $f(p-a)$, and here a is minus 1 and for Laplace of e^{kt} power minus $t \sin t$ by t . So, it is $f(t)$ by t , and for $f(t)$ by t we are having for Laplace of $f(t)$ by t . What we have? We have Laplace of $f(t)$ by t , it is p to infinity $f(u)$ du Laplace of $f(t)$ by t is nothing, but p to infinity $f(u)$ du . So, this we can easily integrate. The integration of this will be you can take $u+1$ as some z . So, this is du equal to dz . So, this is nothing, but when this is p , it is $p+1$ and when it this is infinity, this is infinity 1 upon t square plus 1 into dt for dz , sorry it is z square it is z square and dz which is nothing, but $\tan^{-1} z$ infinity plus 1 to infinity, and it is $\frac{\pi}{2}$ minus \tan^{-1} of $p+1$.

So, we have find Laplace of this. Now for 0 to t it is nothing, but $F(p)$ by p where $F(p)$ is nothing, but Laplace transform of $f(t)$, here $f(t)$ is a entire expression. So, Laplace transform of $f(t)$ is this. So, this is a $F(p)$ this is $F(p)$. So, what is Laplace transform of this? This is nothing, but $\frac{\pi}{2}$ minus $\tan^{-1} p+1$ upon p , this property we use. Now

$\int_0^t \int_0^t t \sin t \, dt \, dt$ is 1 by p F p . Now for the last problem for the third problem of this slide we have to take, use this property 2 types $\int_0^t \int_0^t t \sin t$. So, first we will find Laplace transform of this expression, and then take this as a $f(t)$ find out Laplace transform of entire expression. So, basically we have to use this property, this property 2 types. So, you can try this problem. Now we can also find Laplace inverse, Laplace inverse of some problems where we have division by p . So, how can we solve the last problem of this slide? Now here we have integral 2 times $\int_0^t \int_0^t t \sin t \, dt \, dt$, where 2 times integral. So, we have to use this property 2 times. So, how can we use this property 2 times? This is what, this is Laplace transform of $\int_0^t \int_0^t t \sin t \, dt \, dt$.

(Refer Slide Time: 28:44)

$$\begin{aligned}
 \mathcal{L}\left\{ \int_0^t \left(\int_0^t t \sin t \, dt \right) dt \right\} &= \frac{\mathcal{L}\left\{ \int_0^t t \sin t \, dt \right\}}{p} \\
 &= \frac{\mathcal{L}\{ t \sin t \}}{p^2}
 \end{aligned}$$

So, first we can find out Laplace transform of this $f(t)$, this is nothing, but $F(p)$ by p where $F(p)$ will Laplace transform of $t \sin t$. So, for $t \sin t$, you can easily find out, you can first find out Laplace of $\sin t$ and using Laplace transform of $t f(t)$ is minus F' dash p . We can find out Laplace transform of $t \sin t$ then this is Laplace of this is $F(p)$ again we will use $\int_0^t f(t) \, dt$ and the same property $F(p)$ by p we can find out Laplace transform of this entire expression.

So, basically this expression will be nothing, but Laplace transform of $\int_0^t \int_0^t t \sin t \, dt \, dt$ upon p the same on to say, and again for Laplace transform of this this is nothing, but Laplace transform of $t \sin t$ upon p square. So, this will be the basically the final

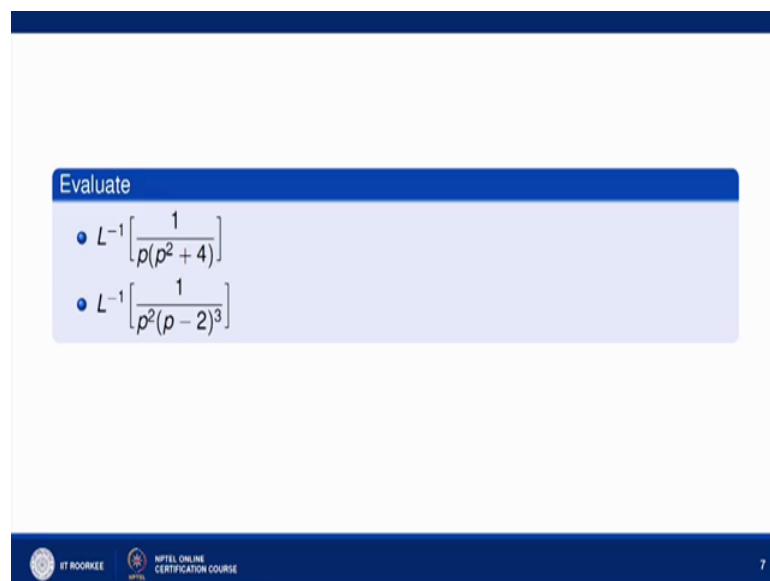

expression for this problem. Now how can you find out Laplace inverse of some problems, where we have division by p F p by p types?

(Refer Slide Time: 30:19)

So, how can you find out? This is Laplace transform of, now F p by p is what - it is 0 to t f t dt f u d u, where Laplace transform of f u is F p. So, here we have Laplace inverse of this expression. So, F p is 1 upon p square plus 4.

(Refer Slide Time: 30:38)

So, Laplace inverse of F p will be nothing, but 1 by 2 sin 2 t. So, if we put it here. So, Laplace inverse of 1 upon p into p square plus 4 will be nothing, but 0 to t. Now this is f t

the Laplace inverse of this $F(p)$. So, this is nothing, but $\frac{1}{2} \int_0^t \sin 2u \, du$. So, this we can easily integrate $\frac{1}{2} \int_0^t \sin 2u$ this minus $\frac{1}{2} \cos 2u$ by $\frac{1}{2}$ minus $\frac{1}{2} \cos 2u$ by $\frac{1}{2}$ from 0 to t . So, solving this we can easily find out Laplace inverse of the first problem. Now, for the second problem, we have to use this property again 2 times, because we have $\frac{1}{p^2}$. We have 2 ways we can use partial fraction also but it is better if you use division by p concept, because that is less time consuming, and it is simple to solve also. What is Laplace inverse of $\frac{1}{(p-2)^3}$?

(Refer Slide Time: 32:00)

The image shows a whiteboard with handwritten mathematical derivations. The first equation is the general Laplace inverse formula: $L^{-1}\left\{\frac{F(p)}{p}\right\} = \int_0^t f(u) \, du$. The second equation shows the Laplace inverse of $\frac{1}{(p-2)^2}$ as $e^{2t} L^{-1}\left\{\frac{1}{p^2}\right\} = e^{2t} \frac{t^2}{2}$. The third equation shows the Laplace inverse of $\frac{1}{p(p-1)^2}$ as $\int_0^t \frac{u^2}{2} e^{-2u} \, du$.

So, that is nothing, but e^{2t} Laplace inverse of $\frac{1}{p^2}$ and for $\frac{1}{p^2}$. It is factorial it is t^k power $p-n+1$ and it is 2. So, it is factorial 2 upon factorial 2, and Laplace inverse of first division by p is nothing, but $\int_0^t f(u) \, du$. And again division by p , so we have to integrate once again 0 to t of this entire expression; so that will give us a final answer.

Thank you very much.
