Lecture - 45
Applications of Z – Transforms – I

(Refer Slide Time: 00:37)

Difference equations model processes in which we know relationships between changes or differences rather than rates of change which lead to the differential equations. Thus, these equations arise in those situations where a sequential relation exists at various discrete values of the independent variable.

Recurrence relation obtained in the solution of differential equations by power series or Frobenius method are also difference equations . Numerical solution of differential equations also leads to difference equations.

IT Roorkee | NPTEL ONLINE CERTIFICATION COURSE 2

Hello friends welcome to my lecture on applications of Z-transforms. So, this we will cover in two lectures, this is first lecture on application of Z-transforms. We know that the difference equations model those processes in which we know relationships between changes and or differences rather than the rates of change which leads to the differential equations. Now, these difference equations arise in those situations where sequential relation exists at various discrete values of the independent variable, the recurrence relation that we obtained while solving the difference equation by power series or Frobenius method are also difference equations. Similarly, numerical solution of differential equations also leads to difference equations.

(Refer Slide Time: 01:13).

In control engineering, often the input is in the form of discrete pulse of short duration and the radar tracking devices receive such discrete pulse from the target which is being tracked.

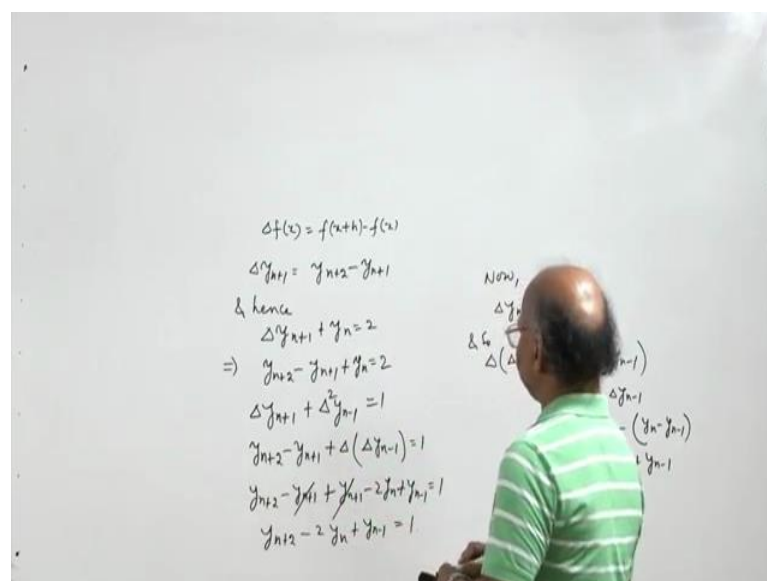

Difference equation:
It is a relation between the differences of an unknown function at one or more general values of the argument.

For example $\Delta y_{n+1} + y_n = 2$... (1)
and $\Delta y_{n+1} + \Delta^2 y_{n-1} = 1$... (2)
are difference equations.

 3

Now, in control engineering, often the input is in the form of discrete pulse of short duration and the radar tracking devices receive such discrete pulse from the target which is being tracked. So, difference equations is a relation between the differences of an unknown function at one or more general values of the argument.

(Refer Slide Time: 01:55)

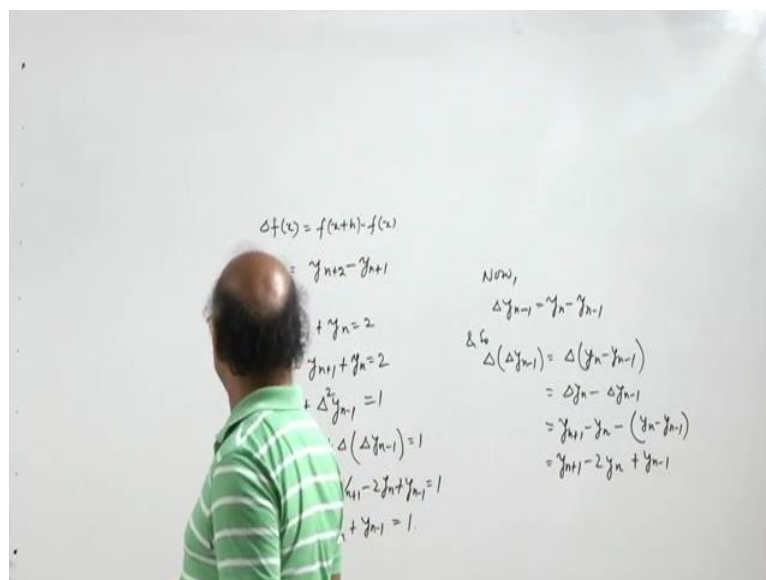

$\Delta f(x) = f(x+h) - f(x)$
 $\Delta^2 y_{n+1} = y_{n+2} - y_{n+1}$
 & hence $\Delta^2 y_{n+1} + y_n = 2$
 $\Rightarrow y_{n+2} - y_{n+1} + y_n = 2$
 $\Delta y_{n+1} + \Delta^2 y_{n-1} = 1$
 $y_{n+2} - y_{n+1} + \Delta(\Delta y_{n-1}) = 1$
 $y_{n+2} - y_{n+1} + y_{n+1} - 2y_n + y_{n-1} = 1$
 $y_{n+2} - 2y_n + y_{n-1} = 1$

Now,
 $\Delta y_n = y_n - y_{n-1}$
 $\Delta(\Delta y_{n-1}) = \Delta(y_n - y_{n-1}) = y_n - y_{n-1} - (y_{n-1} - y_{n-2}) = y_n - 2y_{n-1} + y_{n-2}$

For example, let us consider $\Delta y_{n+1} + y_n = 2$, this Δ is the forward difference, and then you can also consider $\Delta y_{n+1} + \Delta^2 y_{n-1} = 1$; both of these equations are difference equations. These two equations can be put in the following form. We know that $\Delta f(x)$ the forward difference of $f(x)$ is $f(x+h) - f(x)$. So, using this definition Δy_{n+1} will be equal to $y_{n+2} - y_{n+1}$. And hence $\Delta y_{n+1} + y_n = 2$ gives us $y_{n+2} - y_{n+1} + y_n = 2$ which is; so alternately the difference equation 1 can be expressed like this.

And similarly the equations 2, the equations 2 is $\Delta y_{n+1} + \Delta^2 y_{n-1} = 1$. So, here we can write it as Δy_{n+1} is first order forward difference. So, we get $y_{n+2} - y_{n+1}$, and $\Delta^2 y_{n-1}$ here is Δ^2 second order forward difference. So, this will be $\Delta(\Delta y_{n-1}) = 1$.

(Refer Slide Time: 03:24)

Now, Δy_{n-1} is equal to $y_n - y_{n-1}$. And so $\Delta(\Delta y_{n-1})$ is equal to $\Delta(y_n - y_{n-1})$ which is equal to $\Delta y_n - \Delta y_{n-1}$, but Δy_n is $y_{n+1} - y_n$, and here this is $y_{n+1} - y_n - (y_n - y_{n-1})$.

So, we will get $y_{n+1} - 2y_n + y_{n-1}$. So, let us substitute the value here, $y_{n+2} - 2y_{n+1} + y_n$ and then $y_{n+1} - 2y_n + y_{n-1}$ equal to 1. So, this cancels y_{n+1} and we get $y_{n+2} - 2y_n + y_{n-1}$ equal to 1. So, the equations one and two can be alternately written in this forms. So, the equations 1 and 2 can be also written as $y_{n+2} - y_{n+1} + y_n = 2$ and $y_{n+2} - 2y_n + y_{n-1} = 1$. Now, let us discuss how can we determine the order of a difference equation.

(Refer Slide Time: 05:01)

Equations (1) and (2) may also be written as

$$y_{n+2} - y_{n+1} + y_n = 2 \quad \dots(3)$$

and

$$y_{n+2} - 2y_n + y_{n-1} = 1 \quad \dots(4)$$

Order of a difference equation:
It is the difference between the largest and the smallest argument occurring in the difference equation divided by the unit of increment .
Thus equation (3) is of second order while (4) is of order 3.

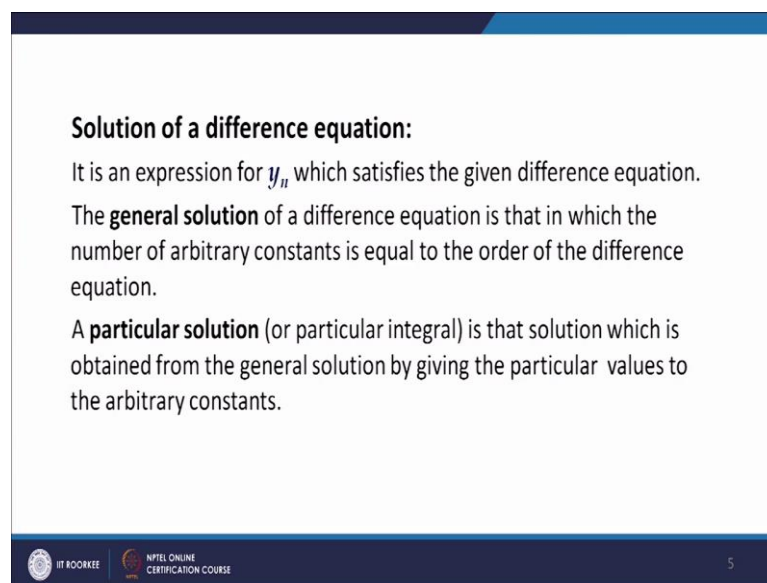

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So, the order of a difference equation defined as the difference between the largest and the smallest argument occurring in the difference equation divided by the unit of increment. So, let us see here this equation, which is alternate form of the first equation number one and this one; and this equation, which is the alternate form of this equation. So, here we see that the largest argument is $n+2$. So, let me call it as equation number three this is equation number 3 and this is equation number 4. So, in 3 largest argument is $n+2$ and then the smallest argument is n divided by the unit of increment, unit of increment is 1 we have $n, n+1, n+2$, so this is 2.

So, this is of second order. And here the largest argument is $n+2$, the smallest argument is $n-1$ divided by the unit of increment is 1. So, we get here 3. So,

equation 1 is of second order, while equation 2 is of third order or we can say equation 3 is of second order and equation 4 is of order three. Now solution of difference equation, so when we have a difference equation the solution is defined as an expression for y_n which satisfies the given difference equation. The general solution of a difference equation is that in which the number of arbitrary constant is equals to the order of the difference equations.

(Refer Slide Time: 06:47)

Solution of a difference equation:

It is an expression for y_n which satisfies the given difference equation.

The **general solution** of a difference equation is that in which the number of arbitrary constants is equal to the order of the difference equation.

A **particular solution** (or particular integral) is that solution which is obtained from the general solution by giving the particular values to the arbitrary constants.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

So, suppose we want to call this difference equation 3, then its general solution must involve two arbitrary constant because here there are where the order of the difference equation is 2. Similarly, the equation 4 is of order three, so the general solution must involve three arbitrary constants. So, general solution will be that solution of the difference equation in which the number of arbitrary constants is equal to the order of the difference equation. Now, particular solution of the difference equation will be obtained from the general solution by assigning arbitrary by assigning the particular values to the arbitrary constants.

(Refer Slide Time: 07:41)

Now, we shall discuss linear difference equations with constant coefficients.

Linear difference equations: it is defined as an equation in which y_{n+1} , y_{n+2} , ... etc. occur to the first degree only and separately.

It is of the form

$$y_{n+k} + a_1 y_{n+k-1} + a_2 y_{n+k-2} + \dots + a_k y_n = f(n) \quad \dots(1)$$

where a_1, a_2, \dots, a_k are constants.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

Let us now discuss how we can solve linear difference equation with constant coefficients. A linear difference equation is defined as an equation in which y_{n+1} , y_{n+2} etcetera that is all y_n plus all the sequences arguments y_{n+1} , y_{n+2} and so on, they occur in the first degree and they occur separately. Like linear difference equation with constant coefficients in general will be of this form $y_{n+k} + a_1 y_{n+k-1} + a_2 y_{n+k-2} + \dots + a_k y_n = f(n)$ where a_1, a_2, a_k are constants. So, here you can see this is k th order difference equation because $n+k$ is the highest or the largest argument and n is the smallest argument. So, $n+k$ minus n divided by one unit of increment is 1. So, it is k th order difference equation, and it is a linear difference equation because y_n , y_{n+k} , y_{n+k-1} and so on y_n they all occur in first degree and separately.

(Refer Slide Time: 08:50)

Properties:

If $u_1(n), u_2(n), \dots, u_k(n)$ be k independent solutions of the equation $y_{n+k} + a_1 y_{n+k-1} + \dots + a_k y_n = 0$,

then $U_n = c_1 u_1(n) + c_2 u_2(n) + \dots + c_k u_k(n)$,
is called **complete solution**.

If V_n is a particular solution of equation (1), then the complete solution of (1) is $y_n = U_n + V_n$.

The part U_n is called the complementary function and the part V_n is called the particular integral.

7

Now, if u_1, u_2, \dots, u_k are k independent solutions of this equation $y_{n+k} + a_1 y_{n+k-1} + \dots + a_k y_n = 0$. So, here we say that k is the order of the difference equation, k is the order of the difference equation. So, let us consider the corresponding homogeneous part. So, $y_{n+k} + a_1 y_{n+k-1} + \dots + a_k y_n = 0$, if u_1, u_2, \dots, u_k are k independent solutions of this homogeneous equation then their linear combination $c_1 u_1 + c_2 u_2 + \dots + c_k u_k$ is called the complete solution of this homogeneous equation. Let us, denoted by say U_n . If V_n is a particular solution of equation (1), if V_n is a particular solution of this non-homogeneous equation then the complete solution of equation (1) will be given by $y_n = U_n + V_n$, where U_n is called the complementary function, and V_n is called the particular integral. Now thus the general solution of the difference equation (1) is the sum of the two that is complementary function and the particular integral.

(Refer Slide Time: 10:02)

Thus, the general solution of (1) is

$$y_n = C.F + P.I.$$

The solution of (1) can be obtained by a classical approach similar to the one used for solving linear non-homogeneous differential equations with constant coefficients .

Here we shall solve equation (1) by using Z- transforms.

IT ROORKEE

NPTEL ONLINE
CERTIFICATION COURSE

8

The solution of one equation one solution of one can be obtained by the classical approach like we just has been solve the linear differential equations with constant coefficients. So, these linear difference equations with constant coefficient can be solved in a analogous manner by the classical approach, but here we will solve them by using the Z-transforms. So, we are solving these linear non-homogeneous difference equations with by using Z-transforms.

(Refer Slide Time: 10:41)

$4u_n - u_{n+2} = 0$, with $u_0 = 0$ and $u_1 = 2$.
 2nd order difference equation
 Taking Z-transform of (1) we have
 $4z(u_n) - z^2(u_{n+2}) = z(0) = 0$
 $4U(z) - z^2(U(z) - u_0 - \frac{u_1}{z}) = 0$
 $4U(z) - z^2(U(z) - 0 - \frac{2}{z}) = 0$

Thus,
 $U(z) = \frac{1}{2} \left[\frac{z}{z-2} - \frac{z}{z+2} \right]$
 Hence
 $u_n = z^{-1}(U(z))$
 $= \frac{1}{2} \left[z^{-1} \left(\frac{z}{z-2} \right) - z^{-1} \left(\frac{z}{z+2} \right) \right]$

$(4-z^2)U(z) + 2z = 0$
 or $U(z) = \frac{2z}{z^2-4}$
 or $\frac{U(z)}{z} = \frac{2}{z^2-4} = \frac{2}{(z-2)(z+2)}$
 $= \frac{2}{4} \left[\frac{1}{z-2} - \frac{1}{z+2} \right]$
 $= \frac{1}{2} \left[\frac{1}{z-2} - \frac{1}{z+2} \right]$

Let us see how we do this. So, suppose we consider, so let us consider $4U_n - U_{n+2} = 0$ with $u_0 = 0$, and $u_1 = 2$. So, we are given this difference equation. You can see the largest argument here is $n + 2$, the smallest argument is n . So, and the unit of increment is 1. So it is the second order difference equation second order difference equation. And they are given two initial conditions the conditions are $u_0 = 0$, so $u_1 = 2$. So, we will get with these two initial conditions we shall get a particular solution of this difference equation.

So, what we do in order to solve this difference equation what we do is we take the Z-transforms of both the sides of the difference equation and then solve this solve the resulting equation for the value of $U(z)$, where $U(z)$ is the Z-transform of this sequence U_n . And then we divide $U(z)$ by z and break $U(z)$ by z into partial fractions in such a way that when we write the corresponding expression for a $U(z)$, it comes in terms of the known Z-transforms, so that while inverting $U(z)$ we get the sequence U_n easily.

So, let us take the Z-transform, taking Z-transforms of both the sides, let me call it equation 1. So, this equation 1, so taking Z-transform of equation 1, we have 4 times z is a linear property. So, 4 times z of U_n minus z of U_{n+2} equal to z of 0 which is 0. So, now, 4 z of U_n is four of $U(z)$, $U(z)$ is the Z-transform this sequence U_n . And here

while writing Z-transform of U_{n+2} , let us recall the shifting to the left shifting of U_n to the left. So, we know that Z-transform of U_{n+k} where k is greater than 0 is equal to z^{-k} times the Z-transform of U_n and then we have $z^{-1}U_n - z^{-2}U_{n-1} + z^{-3}U_{n-2} - \dots + (-1)^{k-1}z^{-k}U_{n-k+1}$.

So, let us apply this formula. So, $z^2 U_n - z U_{n-1} + U_{n-2} = 0$. Let us make use of the given conditions $U_0 = 0$, $U_1 = 2$. So, $4z^2 - z^2 U_n - z^2 U_{n-1} + z^2 U_{n-2} = 0$. So, the coefficient of z^n is $4 - z^2$ and then we get $z^2 U_n - z U_{n-1} + U_{n-2} = 0$. We can write it as $z^2 U_n = z U_{n-1} - U_{n-2}$. Now let us write $z^2 U_n$ by z we break $z^2 U_n$ into partial fraction. So, $\frac{2}{z^2 - 4}$ which is $\frac{2}{z-2} - \frac{2}{z+2}$. The partial fraction of this expression is $\frac{1}{z-2} - \frac{1}{z+2}$ divided by 2. So, this is $\frac{1}{2} \left(\frac{1}{z-2} - \frac{1}{z+2} \right)$.

Now, we can write $z^2 U_n$ from here. So, $z^2 U_n = \frac{1}{2} \left(\frac{z}{z-2} - \frac{z}{z+2} \right)$. And hence U_n which is z^{-2} inverse of $z^2 U_n$ is equal to $\frac{1}{2} \left(\frac{z^{-1}}{z-2} - \frac{z^{-1}}{z+2} \right)$. Let us recall that Z-transform of a^n is $\frac{z}{z-a}$ provided $|z| > |a|$. So, $z^{-1} \frac{z}{z-2}$ will be 2^{-n} . So, here we have $\frac{1}{2} (2^{-n} - (-2)^{-n})$ and for this $|z|$ must be greater than 2 and then from here we get $U_n = \frac{1}{2} (2^{-n} - (-2)^{-n})$.

So, here also $|z|$ must be greater than 2. So, $|z|$ must be greater than 2 for this to be true. So, $\frac{1}{2} (2^{-n} - (-2)^{-n})$ we can simplify it further to $\frac{1}{2} (2^{-n} - (-1)^n 2^{-n})$ and then I can write it as $\frac{1}{2} (1 - (-1)^n)$. I can take from here. So, $U_n = \frac{1}{2} (1 - (-1)^n)$. So, this is the sequence $U_n = \frac{1}{2} (1 - (-1)^n)$ which is the solution of example 1.

(Refer Slide Time: 17:38)

$$u_{n+2} + 4u_{n+1} + 3u_n = 3^n, \quad u_0 = 0, u_1 = 1$$

$$z^2(u_{n+2}) + 4z(u_{n+1}) + 3z(u_n) = z(3^n)$$

$$z^2\left[u(z) - u_0 - \frac{u_1}{z}\right] + 4z\left[u(z) - u_0\right] + 3u(z) = \frac{z}{z-3}, \quad |z| > 3$$

$$z^2\left[u(z) - 0 - \frac{1}{z}\right] + 4z\left[u(z) - 0\right] + 3u(z) = \frac{z}{z-3}$$

$$(z^2 + 4z + 3)u(z) = \frac{z}{z-3} + \frac{1}{z} = \frac{z^2 - 2z}{z-3}$$

$$\text{Thus } \frac{u(z)}{z} = \frac{(z-2)}{(z-3)(z+1)(z+3)} = \frac{A}{z-3} + \frac{B}{z+1} + \frac{C}{z+3}$$

$$A = \frac{(z-2)}{(z+1)(z+3)} \Big|_{z=3} = \frac{1}{24}$$

$$B = \frac{(z-2)}{(z-3)(z+3)} \Big|_{z=-1} = \frac{-3}{(-4)(2)} = \frac{3}{8}$$

$$C = \frac{(z-2)}{(z-3)(z+1)} \Big|_{z=-3} = \frac{-5}{(-6)(2)} = \frac{5}{12}$$

Now let us take the example 2. So, here we have this sequence $U_{n+2} + 4U_{n+1} + 3U_n = 3^n$. Again let us see $n+2$ is the largest argument and n is the smallest argument here. So, $n+2$ minus n divided by the unit of increment is 1, this means the order of this difference equation is $n+2$ minus n divided by 1, so that is 2, this is the order of the difference equation. So, this is second order difference equation. Let us solve this. Here we are given the initial conditions u_0 equal to 0, and u_1 equal to 1. So, the general solution of this difference equation will involve two arbitrary constants, to determine two arbitrary constants we are given two conditions u_0 equal to 0 and u_1 equal to 1. So, this will give us a particular solution of the difference equation.

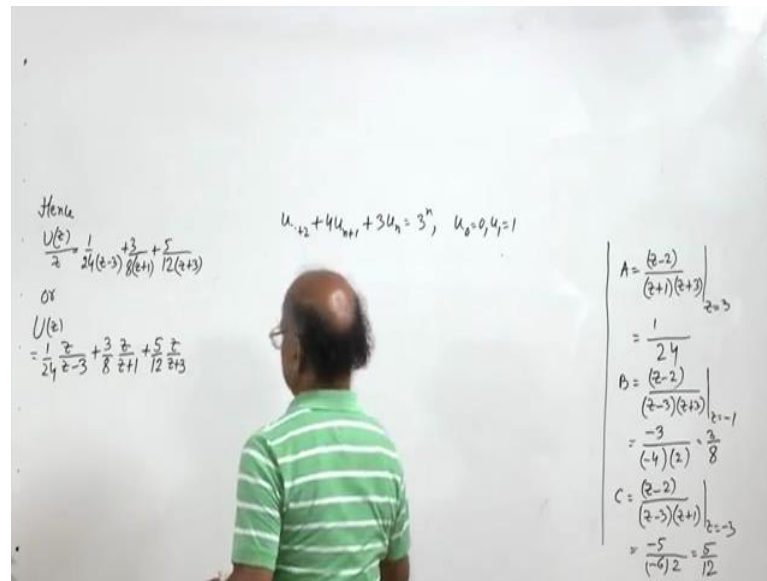

Now, let us take Z-transform here. So, Z-transform is a linear operation. So, z of $U_{n+2} + 4z$ of $U_{n+1} + 3z$ of $U_n = Z$ -transform of 3^n . Now again let us apply this shifting of U_n to the left. So, z of U_{n+2} will be $z^2 u(z)$, where $u(z)$ is Z-transform of the U_n sequence minus u_0 minus u_1 by z plus 4 times z of U_{n+1} will be z times $u(z)$ minus u_0 plus 3 times Z-transform of U_n is $u(z)$ equal to z over $z-3$ provided $\text{mod of } z > 3$.

Now, let us use the values of u_0 and u_1 which are given to us, u_0 is given to be 0. So, $u(z) - 0 - u_1 = \frac{1}{z+4} - \frac{1}{z+3}$. Let us collect the coefficient of $u(z)$. So, $z^2 + 4z + 3$ into $u(z)$ we have, and then we have z^2 by z , so $z - z$ when goes to the other side becomes $+z$, so $\frac{z}{z+3} + z$. And this will give you $z^2 - 2z$ divided by $z+3$.

Now, let us find $u(z)$ by z from here. So, then $u(z)$ by z , it will be equal to $\frac{z-2}{z+3}$ into $z^2 + 4z + 3$, if you factorize you get $(z+1)(z+3)$. So, $\frac{z-2}{(z+1)(z+3)}$, now, we have to break this $u(z)$ by z into partial fractions and then determine the inverse Z-transform. So, $u(z)$ by z , so let us write it as $\frac{a}{z+3} + \frac{b}{z+1}$. The values of a, b, c can be obtained, now a is equal to $\frac{z-2}{z+1}$ evaluated at $z = -3$. So, this will be equal to $\frac{-3-2}{-3+1} = \frac{-5}{-2} = \frac{5}{2}$ and $\frac{3+1}{3+3} = \frac{4}{6} = \frac{2}{3}$. So, it is $\frac{5}{2} + \frac{2}{3}$.

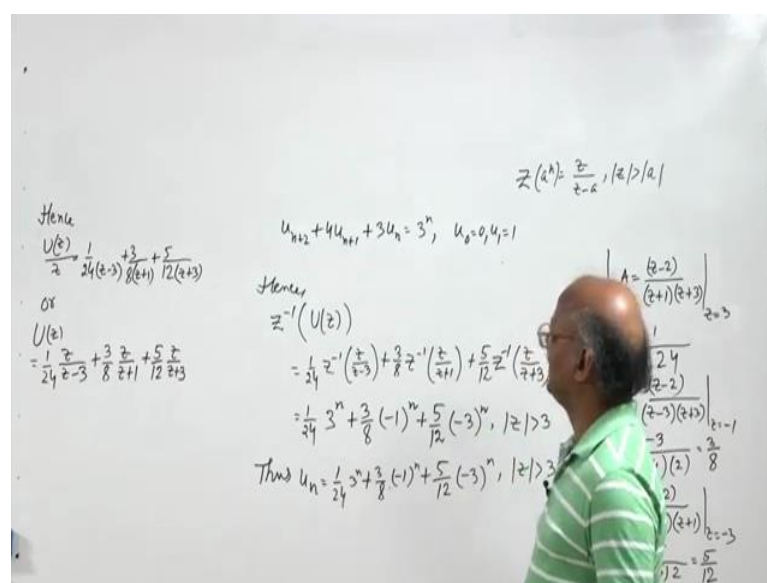

B will be equal to $\frac{z-2}{z+3}$ evaluated at $z = 1$ minus $\frac{z-2}{z+1}$ evaluated at $z = -3$. So, we get this $\frac{1-2}{1+3} - \frac{-3-2}{-3+1} = \frac{-1}{4} - \frac{-5}{-2} = \frac{-1}{4} - \frac{5}{2} = \frac{-1-10}{4} = \frac{-11}{4}$. So, $\frac{3}{8}$ and c we will have as $\frac{z-2}{z+3}$ into $z+1$ evaluated as $z = -3$. So, this will be $\frac{-3-2}{-3+3}$. And here we will have $\frac{-3-2}{-3+3} = \frac{-5}{0}$ which is undefined. So, $\frac{3}{8}$ and $\frac{-11}{4}$.

(Refer Slide Time: 23:54)

And hence $u(z)$ by z is equal to $\frac{1}{24} \frac{z}{z-3}$, $\frac{3}{8} \frac{z}{z+1}$ and then we have $\frac{5}{12} \frac{z}{z+3}$. Now, we can multiply by z . So, this gives $u(z)$ is equal to $\frac{1}{24} \frac{z}{z-3} + \frac{3}{8} \frac{z}{z+1} + \frac{5}{12} \frac{z}{z+3}$. Now we can easily invert this.

(Refer Slide Time: 25:09)

So, let us take the inverse Z-transform. So, this was U_n plus 2 here. So, z then hence z inverse of $u z$ is equal to 1 by $24 z$ inverse of z over z minus 3 plus 3 by $8 z$ inverse of z over z plus 1 and then we have 5 by $12 z$ inverse of z over z plus 3 . Again let us recall that z^{-a} is equal to z^{-a} where $\text{mod of } z \text{ is greater than } a$, let us apply this formula. So, z^{-3} , so this is 1 by $24 z^3$ to the power n , where $\text{mod of } z \text{ is greater than } 3$ and then 3 by 8 here minus 1 to the power a is minus 1 and here $\text{mod of } z \text{ is greater than } 1$. So, $\text{mod of } z \text{ is greater than } 3$ here, here $\text{mod of } z \text{ is greater than } 1$, then 5 by 12 minus 3 to the power n . So, here a is minus 3 and therefore, $\text{mod of } z \text{ is greater than } 3$. So, the common reason is $\text{mod of } z \text{ is greater than } 3$ and z^{-a} is U_n . So, thus U_n is 1 by $24 z^3$ to the power n plus 3 by 8 minus 1 to the power n plus 5 by 12 minus 3 to the power n where $\text{mod of } z \text{ is greater than } 3$.

So, this is the answer to this difference equation by taking Z-transform, Z-transform takes care of the initial conditions, we do not have to use initial conditions after we have found this solution like we do in this classical approach. So, here this how we apply the transform techniques, first we take the Z-transform of the given difference equation. Collect the coefficient of $u z$, rest of the terms be tend to the right side divide by the coefficient of $u z$, and then break then you write $u z$ by z then these expression of $u z$ by z is then broken in to partial fractions. In such a way that, we while multiplying by z , we get the expressions in terms of the Z-transform of known Z-transforms. So, that while inverting we get easily the sequence U_n . So, U_n here can be obtained like this.

In our next lecture, we shall discuss some more problems, where we will have to be very careful while writing $u z$ by z because there in the problems the expressions, we will have to arrange of $u z$ by z , so that while inverting we get the sequence even very easily. So, we will do that in the next lecture. With that, I would like to conclude my lecture.

Thank you very much for your attention.
