Lecture – 05
Methods of undetermined coefficients

Hello friends. Welcome to my lecture on Method of Undetermined Coefficients. This method we will be used to solve second order linear differential equations, which are non-homogenous, that they are of the form $y'' + ay' + by = r(x)$. Now we have already solved the homogenous linear second order differential equations.

(Refer Slide Time: 00:32)

Method of undetermined coefficients

This method is applicable to equations

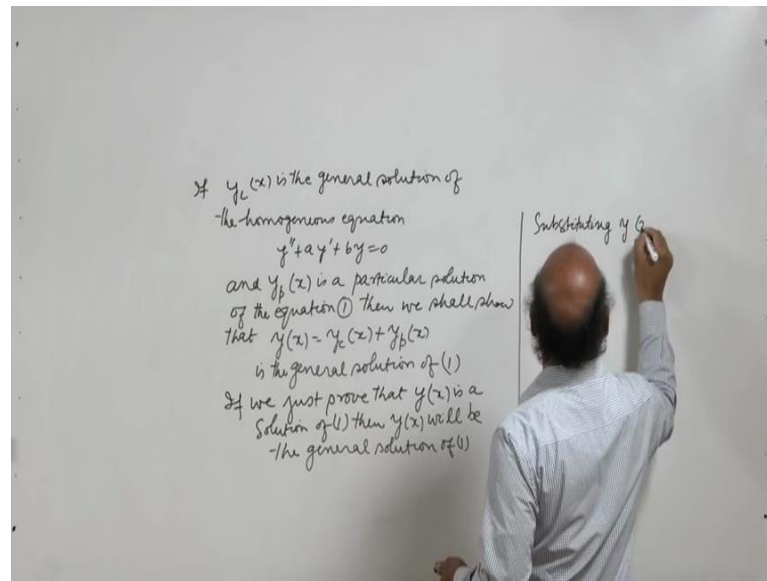

$$y'' + ay' + by = r(x), \quad \dots(1)$$

where, $r(x)$ may be a **polynomial function**, an **exponential function**, a **sine** or **cosine** function or a sum or a product of such functions.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 2

So, let us see how we shall solve this second order non homogenous linear differential equation.

(Refer Slide Time: 00:57)

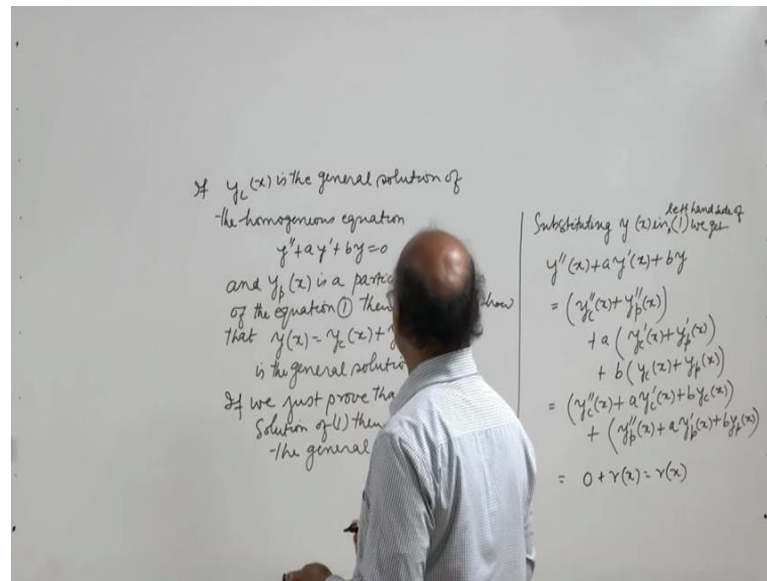

First of all, we shall show that if $y_c(x)$ is the general solution of the homogeneous equation $y'' + ay' + by = 0$ and $y_p(x)$ is a particular solution of the non-homogeneous equation of the equation (1), then we shall see that show that $y(x) = y_c(x) + y_p(x)$ is the general solution of equation (1). So, $y_c(x)$ is the general solution of the homogeneous equation $y'' + ay' + by = 0$ means $y_c(x)$ will contain 2 arbitrary constants.

And we know how to get the solution of this homogeneous equation, $y_p(x)$ is a particular solution of the equation (1) means $y_p(x)$ is a solution of the equation (1), without any arbitrary constants. So, if we can show that $y(x) = y_c(x) + y_p(x)$ is a solution of the equation (1), then $y(x)$ because it contains 2 arbitrary constants, will be the general solution of equation (1), $y(x)$ contains 2 arbitrary constants, because $y_c(x)$ contains 2 arbitrary constants. And $y_p(x)$ is a solution of equation (1) without any arbitrary constants.

So, if we just prove that $y(x)$ is a solution of equation (1), then $y(x)$ will be the general solution of (1). So, let us see when you substitute $y(x) = y_c(x) + y_p(x)$, if it satisfies the equation (1), it will be a solution of equation (1).

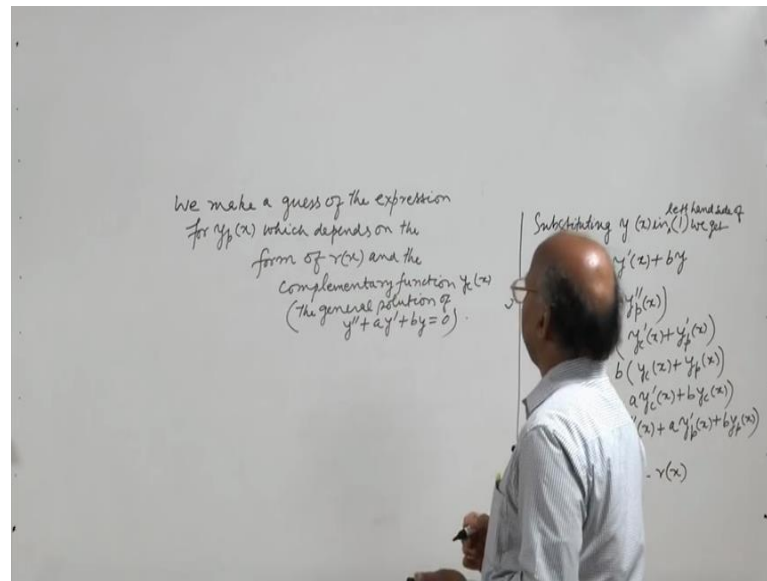

(Refer Slide Time: 04:00)

So, substituting in the left hand side of one, we get $y''(x) + ay'(x) + by(x)$, equal to $y_c''(x) + ay_c'(x) + by_c(x) + a(y_p'(x) + y_p'(x)) + b(y_c(x) + y_p(x))$. We can write it as $y_c''(x) + ay_c'(x) + by_c(x) + a(y_p'(x) + y_p'(x)) + by_p(x)$. Now since $y_c(x)$ is a general solution of $y'' + ay' + by = 0$. So, this first expression is 0. Then we have now $y_p(x)$ is a particular solution of the equation 1, therefore, $y_p''(x) + ay_p'(x) + by_p(x) = r(x)$. And thus we get $y(x)$ is a solution of equation 1. Again I repeat $y(x)$ will therefore, be the general solution of equation 1.

So, if we are having a non-homogenous second order linear differential equation with constant coefficients, then we will now discuss a method by which we can determine this particular solution $y_p(x)$, $y_c(x)$ we know how to determine. So, our now method will determine the value of $y_p(x)$. So, the method that we are going to discuss is called as the method of undetermined coefficients. In this method the by we make an educated guess for $y_p(x)$ the particular solution $y_p(x)$ of the equation 1 which we are looking for.

(Refer Slide Time: 07:08)

So, we make a guess of the expression for $y_p(x)$, which depends on the form of $r(x)$, and the complimentary function. This complimentary function is nothing but the general solution of the associated homogenous equation. Complementary function is nothing but the general solution of. So, I can say $y_c(x)$. So, this is not an arbitrary guess. It is a it is called an educated guess, because it depends on the form of $r(x)$, and also sometimes it depends on the form of the complimentary function $y_c(x)$.

Now, this expression for $y_p(x)$ will contain constants which will be determined by substituting $y_p(x)$ in the equation 1. So, that is why we call this method as method of undetermined coefficients. Now here we have certain detritions. This method can be applied to the second order linear differential equation which are non-homogenous, when $r(x)$ is of the following type. It can be a polynomial function, it can be an exponential function, it can be a sin or cosine function or a sum or products of such functions.

(Refer Slide Time: 09:30)

$r(x)$ is a linear combination of functions of the type
 $P(x) = a_0 + a_1x + a_2x^2 + \dots + a_nx^n$, $P(x)e^{\alpha x}$, $P(x)e^{\alpha x}\cos\beta x$,
 $P(x)e^{\alpha x}\sin\beta x$,
where n is a non negative integer and α and β are real numbers.

We cannot apply this method to (1) if
 $r(x) = \log x$, x^{-1} , $\tan x$, $\sin^{-1}x$, etc.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

Now, or you can take linear combination of the functions which are polynomials or exponential functions or trigonometric functions $\sin x$ cosine x . So, p with p you can take $r(x)$ to be function of the form $p(x)$, or you can take $p(x)$ into e to the power αx , $r(x)$ e to the power $\alpha x \cos \beta x$, $r(x)$ e to the power αx and βx . So, $r(x)$ is a function of this type, where n is non negative integer and α and β are real numbers, then we can apply this method of undetermined coefficients.

Now, if $r(x)$ is of the type $\log x$ $r(x)$ to the power minus 1 or $\frac{1}{x}$ or $\sin^{-1}x$, then this method cannot be applied. So, for second order non homogenous linear differential equations, where $r(x)$ is of those types $\log x$ $\frac{1}{x}$ $\sin^{-1}x$ etcetera, then we will apply the general method which we shall discuss in the next lecture now. So, in the general method, we will be taking care of all the functions $r(x)$ which cannot be handled by the method of undetermined coefficients.

(Refer Slide Time: 10:36)

Such kind of functions will be dealt with in the general method.

Note that the set of functions that consists of **constants**, **polynomials**, **exponentials**, **sines** and **cosines** have the remarkable property that the derivative of the sums and products are again sums and products of similar kinds of functions. It appears reasonable to assume that $y_p(x)$ has the same form as $r(x)$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Now, let us see if you take the constants, polynomials, exponentials, sines or cosines, the remarkable property of those functions is that, the derivatives of the sums and products of such functions are again sums and products of similar kind of functions. So, in order to assume the form of $y_p(x)$, it is reasonable to assume the same form as that of $r(x)$.

Now, let us take an example say $y'' + 4y' - 2y = 2x^2 - 3x + 6$. So, here we can see $r(x)$ is a polynomial in x of degree 2.

(Refer Slide Time: 11:13)

Example:

$$y'' + 4y' - 2y = 2x^2 - 3x + 6.$$

First, we find $y_c(x)$.

The auxiliary equation is

$$m^2 + 4m - 2 = 0$$

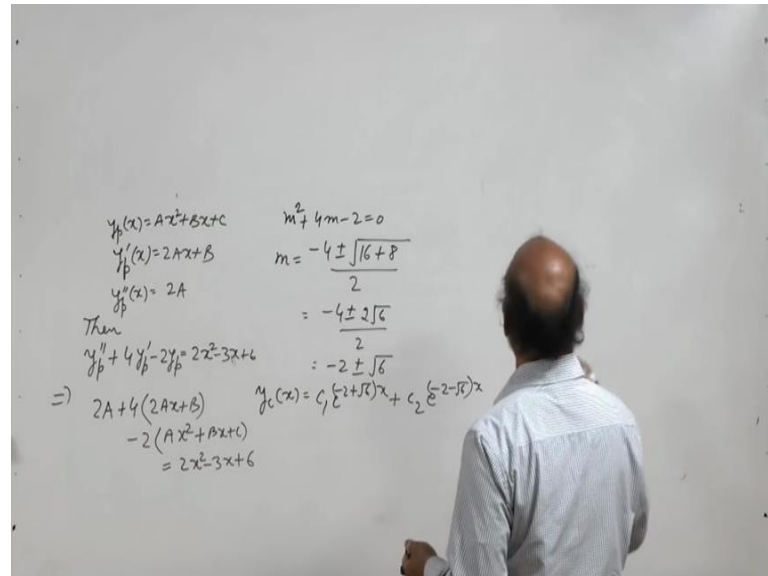

Hence,

$$y_c(x) = c_1 e^{(2+\sqrt{6})x} + c_2 e^{(-2-\sqrt{6})x}.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

Now, first we shall find y_c . So, to find y_c we have to write the auxiliary equation $m^2 + 4m - 2 = 0$, we can find the value of m for this.

(Refer Slide Time: 11:24)

So, this will come out to be minus 4 plus minus. So, m has 2 distinct values minus 2 plus root 6 and minus 2 minus root 6 and therefore, y_c is equal to $c_1 e^{(-2 + \sqrt{6})x} + c_2 e^{(-2 - \sqrt{6})x}$.

Now, since $r(x)$ is equal to $2x^2 - 3x + 6$, which is the polynomial of degree 2.

(Refer Slide Time: 12:25)

Since $r(x) = 2x^2 - 3x + 6$,
 let us assume that

$$y_p = Ax^2 + Bx + C$$
 Substituting y_p into the given differential equation,
 we get an identity, the coefficient of like powers of x must be equal. So $A = -1$, $B = -5/2$ and $C = -9$.
 Thus

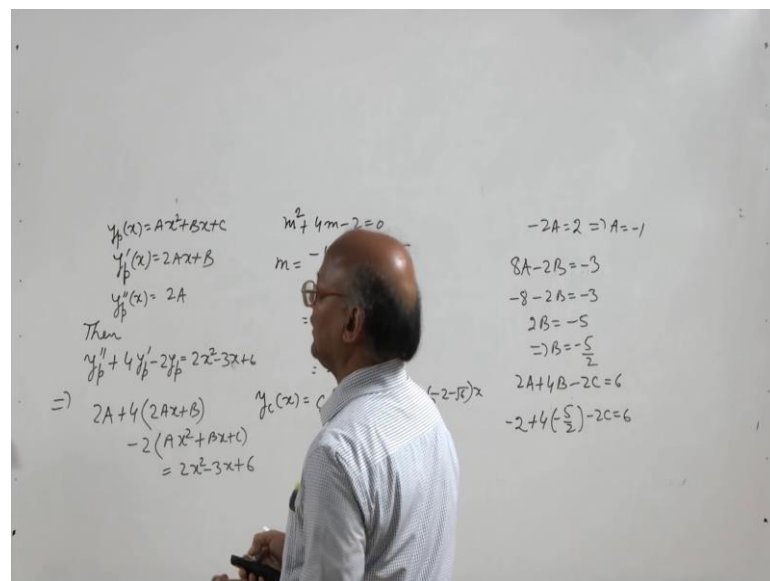

$$y_p(x) = -x^2 - (5/2)x - 9.$$
 The general solution is

$$y = c_1 e^{(-2 + \sqrt{6})x} + c_2 e^{(-2 - \sqrt{6})x} - x^2 - (5/2)x - 9.$$

Let us assume $y_p(x)$ to be equal to $Ax^2 + Bx + C$; a polynomial in x of degree 2 where A, B, C are undetermined coefficients. We shall determine the values of these undetermined coefficients A, B, C by substituting this y_p in to the in the given differential equation, because y_p is a particular solution of the given differential equation. So, it should satisfy that equation. So, let us put y_p equal to $y_p(x) = Ax^2 + Bx + C$. Let us put this value $y_p(x)$ in the given equation, $y'' - 4y' + 2y = 2x^2 - 3x + 6$. So, let us find $y_p''(x) = 2A$.

So, then $y_p'' + 4y_p' - 2y_p = 2x^2 - 3x + 6$ gives us $2A$. Now this equation is valid for all values of x . So, it must be an identity. And therefore, the coefficient of like powers of x must be same. So, if we equate the coefficients of like powers of x , we get the values of the unknown coefficients A, B, C . You can see that here x^2 coefficient x^2 is minus $2A$.

(Refer Slide Time: 14:35)

So, $-2A = 2$, which gives us $A = -1$. When we equate the coefficient of x on both sides we get $8A - 2B = -3$. Putting the value of $A = -1$ we get $-8 - 2B = -3$. So, this will give you $2B = -5$, which gives you $B = -5/2$. And when you equate the coefficients on both sides we get $2A + 4B - 2C = 6$. So, substituting the values of A and B as -1 and $-5/2$, we shall have $C = -9/2$ and thus $y_p(x)$ will be equal to $x^2 - 5/2x - 9/2$.

So, the general solution of this differential equation is the sum of the complimentary function $C_1 e^{(1 + i\sqrt{3})x/2} + C_2 e^{(1 - i\sqrt{3})x/2}$ and then $\frac{x^2}{2} - 9x$. Now let us take another example, $y'' - y' + y = \sin 3x$.

(Refer Slide Time: 16:20)

Example:

$$y'' - y' + y = \sin 3x.$$

The auxiliary equation is $m^2 - m + 1 = 0$

$$m = \frac{1 \pm i\sqrt{3}}{2}$$

$$y_c = e^{\frac{x}{2}} \left(c_1 \cos \frac{\sqrt{3}}{2} x + c_2 \sin \frac{\sqrt{3}}{2} x \right).$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 7

Here the auxiliary equation is $m^2 - m + 1 = 0$. You can find the values of m they are $\frac{1 \pm i\sqrt{3}}{2}$. So, we can write the complimentary function, because these are complex roots. So, $e^{\alpha x}$ that is $e^{\frac{x}{2}}$ into $c_1 \cos \theta x + c_2 \sin \theta x$ where θ is $\frac{\sqrt{3}}{2}$. So, $c_1 \cos \frac{\sqrt{3}}{2} x + c_2 \sin \frac{\sqrt{3}}{2} x$.

Now, let us make an guess for $y_p(x)$. So, the natural guess when you look at the form of $r(x)$ is equal to $\sin 3x$. So, natural guess for the $y_p(x)$ would be that we write $A \sin 3x$, but then when you differentiate $\sin 3x$ it produces $3 \cos 3x$.

(Refer Slide Time: 17:08)

A natural first guess for $y_p(x)$ would be $y_p(x) = A \sin 3x$ but since successive differentiation of $\sin 3x$ produce both $\sin 3x$ and $\cos 3x$.

We should assume $y_p(x) = A \cos 3x + B \sin 3x$
 i.e., a form which includes both $\sin 3x$ and $\cos 3x$.

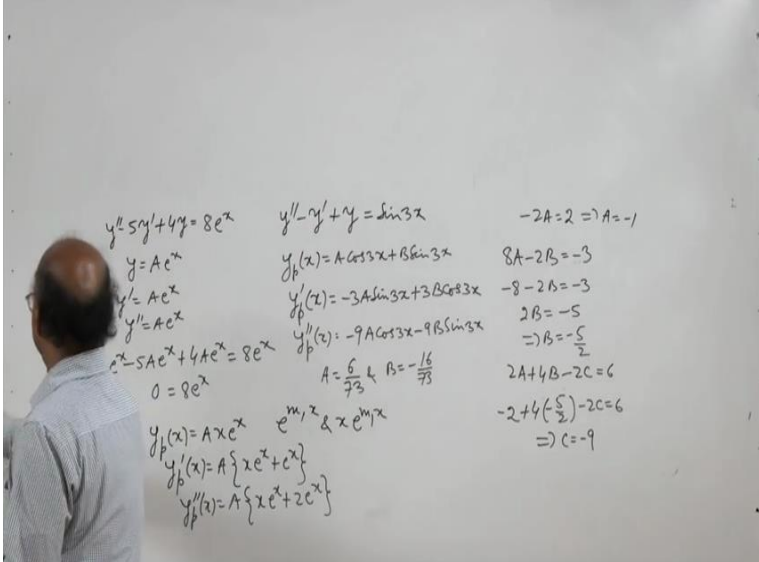

Substituting $y_p(x)$ into the given differential equation, we get

$$A = \frac{6}{73}, \text{ and } B = -\frac{16}{73}.$$

8

And then when you differentiated again you get $\sin 3x$. So, the differentiation of $\sin 3x$ produces both $\sin 3x$ and $\cos 3x$, and therefore, what we should do is we should assume $y_p(x)$ to be a linear combination of $\sin 3x$ and $\cos 3x$ functions. So, let us assume $y_p(x)$ to be having both the functions $\sin 3x$ and $\cos 3x$ that is $A \cos 3x$ plus $B \sin 3x$.

(Refer Slide Time: 17:44)

$y'' - 4y' + 4y = 8e^x$
 $y = Ae^{2x}$
 $y' = 2Ae^{2x}$
 $y'' = 4Ae^{2x}$
 $4Ae^{2x} - 8Ae^{2x} + 4Ae^{2x} = 8e^x$
 $0 = 8e^x$

$y'' - 4y' + 4y = \sin 3x$
 $y_p(x) = A \cos 3x + B \sin 3x$
 $y_p'(x) = -3A \sin 3x + 3B \cos 3x$
 $y_p''(x) = -9A \cos 3x - 9B \sin 3x$
 $A = \frac{6}{73}, B = -\frac{16}{73}$

$-2A = 2 \Rightarrow A = -1$
 $8A - 2B = -3$
 $-8 - 2B = -3$
 $2B = -5$
 $\Rightarrow B = -\frac{5}{2}$
 $2A + 4B - 2C = 6$
 $-2 + 4(-\frac{5}{2}) - 2C = 6$
 $\Rightarrow C = -9$

Now, then you substitute this $y_p(x)$ in the given differential equation, the given differential equation is $y'' - 4y' + 4y = \sin 3x$. So, if you take $y_p(x)$ equal to $A \cos 3x$ plus $B \sin 3x$. And then put it in the given differential equation,

what you will get is unequating the coefficients of $\sin 3x$ and $\cos 3x$ both sides, we shall get a to be $\frac{6}{73}$ and B to be $-\frac{16}{73}$.

So, we can find y_p here this is $-\frac{6}{73} \cos 3x + \frac{16}{73} \sin 3x$. We differentiate it again should will give you $-\frac{18}{73} \sin 3x + \frac{48}{73} \cos 3x$. Now substitute the values of y_p , y_p' , y_p'' in this differential equation, and equate the coefficient of $\sin 3x$ and $\cos 3x$ both sides, we shall get a equal to $\frac{6}{73}$ and B equal to $-\frac{16}{73}$.

(Refer Slide Time: 19:10)

Hence
$$y_p(x) = \frac{6}{73} \cos 3x - \frac{16}{73} \sin 3x .$$

and so the general solution is

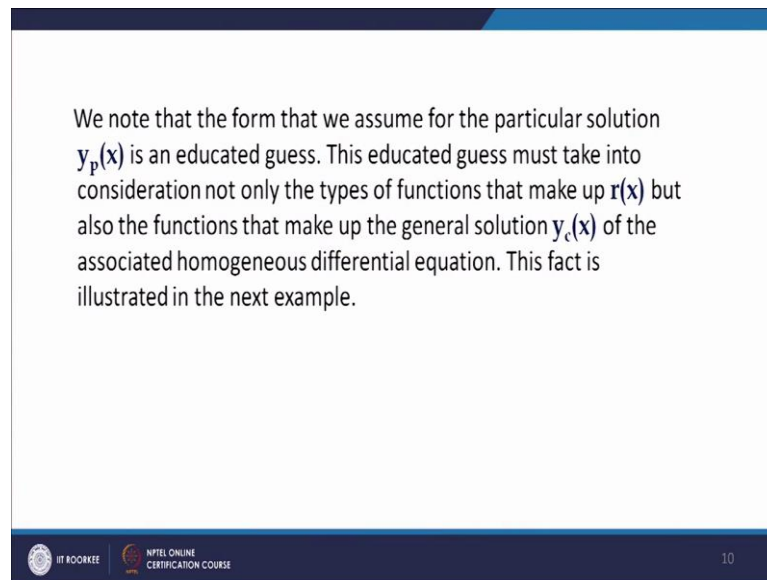

$$y(x) = e^{\frac{x}{2}} \left(c_1 \cos \frac{\sqrt{3}}{2} x + c_2 \sin \frac{\sqrt{3}}{2} x \right) + \frac{6}{73} \cos 3x - \frac{16}{73} \sin 3x$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

So, we will get y_p to be equal to $-\frac{6}{73} \cos 3x + \frac{16}{73} \sin 3x$. And thus the general solution y is the sum of the complementary function. This is the complimentary function plus the particular integral. The particular solution of the equation 1 is also called as particular integral; so $\frac{6}{73} \cos 3x - \frac{16}{73} \sin 3x$.

(Refer Slide Time: 19:43)

We note that the form that we assume for the particular solution $y_p(x)$ is an educated guess. This educated guess must take into consideration not only the types of functions that make up $r(x)$ but also the functions that make up the general solution $y_c(x)$ of the associated homogeneous differential equation. This fact is illustrated in the next example.

Now, now let us look at this comment. Here the as I said in the beginning $y_p(x)$ is not an arbitrary. It is not guessed arbitrary, it is an educated guess, because it depends on the form of $r(x)$, the functions that make up $r(x)$, as well as the functions that make up the complimentary function, which is the solution of the associated homogenous linear differential equation, that is $y'' + ay' + by = 0$ let us see how it depends on the complimentary function. We have seen that the function $y_p(x)$ depends on the form of $r(x)$, in the next example we shall see how $y_p(x)$ depends on the form of the complimentary function.

(Refer Slide Time: 20:23)

Example. $y'' - 5y' + 4y = 8e^x$.

The auxiliary equation is

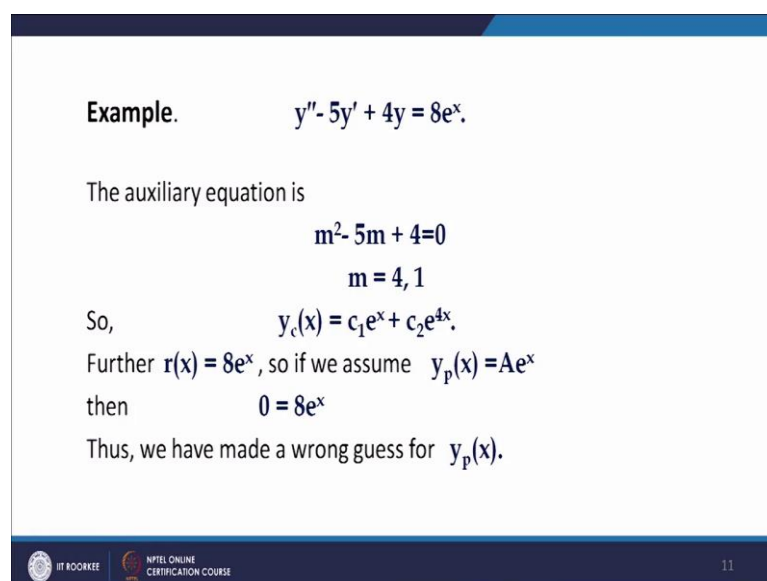

$$m^2 - 5m + 4 = 0$$
$$m = 4, 1$$

So, $y_c(x) = c_1e^x + c_2e^{4x}$.

Further $r(x) = 8e^x$, so if we assume $y_p(x) = Ae^x$

then $0 = 8e^x$

Thus, we have made a wrong guess for $y_p(x)$.

So, let us take up this this problem, $y'' - 5y' + 4y = 8e^{4x}$. Here we can write the auxiliary equation as $m^2 - 5m + 4 = 0$. So, we get 2 values of m which are 4 and 1 they are distinct values. So, the complementary function we can write easily, $y_c(x) = c_1 e^{4x} + c_2 e^x$.

Now, when we look at the form of $r(x)$, $r(x)$ is $8e^{4x}$, and successive differentiation of e^{4x} produce e^{4x} . So, we can assume $y_p(x)$ to be equal to Ae^{4x} , but when you put $y_p(x) = Ae^{4x}$ in this equation in the given differential equation, $y'' - 5y' + 4y = 8e^{4x}$. Let us see what happens, y we are taking as Ae^{4x} . So, let us find y' it is $4Ae^{4x}$. Let us find y'' it is again $16Ae^{4x}$. So, $16Ae^{4x} - 5(4Ae^{4x}) + 4(Ae^{4x}) = 8e^{4x}$ now this is $16Ae^{4x} - 20Ae^{4x} + 4Ae^{4x} = 8e^{4x}$. So, this is $0 = 8e^{4x}$, which is not correct of course, because e^{4x} is never 0. So, thus we have made a wrong guess for $y_p(x)$. So, what should be the form of $y_p(x)$.

(Refer Slide Time: 21:59)

Let us examine the function

$$y_c(x) = c_1 e^{4x} + c_2 e^x,$$

It follows that e^x is a solution of $y'' - 5y' + 4y = 0$ and so Ae^x when substituted into the given differential equation produces zero on left side.

What should therefore be the form of $y_p(x)$?

Let us recall the case of repeated real roots of the homogeneous linear differential equations with constant coefficients. By this case let us see whether $y_p(x) = Axe^x$ can be assumed.

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 12

Now, let us look at the complimentary function. The complimentary function is $c_1 e^{4x} + c_2 e^x$. And therefore, e^{4x} and e^x are both solutions of the associated homogenous linear differential equation of

5 A e to the power x equal to 8 e to the power x. So, we get minus 3 A e to the power x is never 0, for any x. So, we can divide by e to the power x, and we get the value of A x minus 8 by 3, and thus y p x we get as minus 8 by 3 x, e to the power x. So, the general solution therefore, is given by c 1 y equal to c 1 e to the power e x plus c 2 e to the power 4 x minus 8 by 3 x e to the power x.

(Refer Slide Time: 25:27)

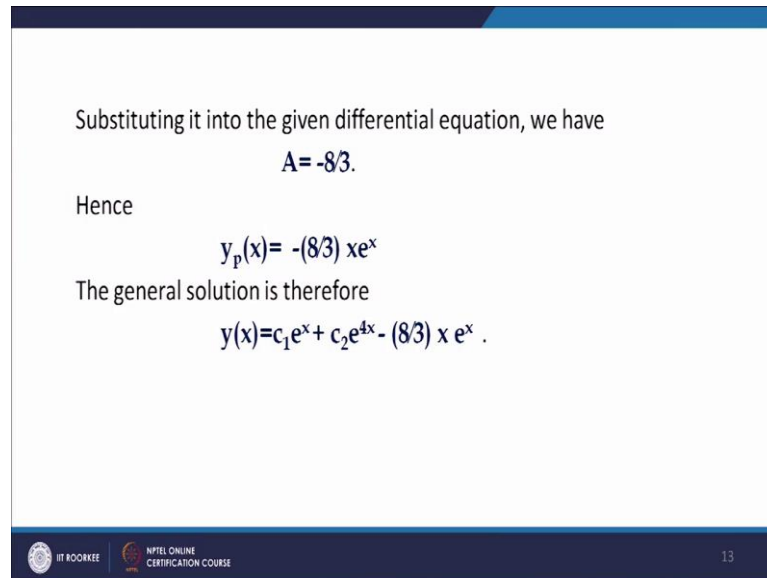

Substituting it into the given differential equation, we have

$$A = -\frac{8}{3}$$

Hence

$$y_p(x) = -\frac{8}{3} x e^x$$

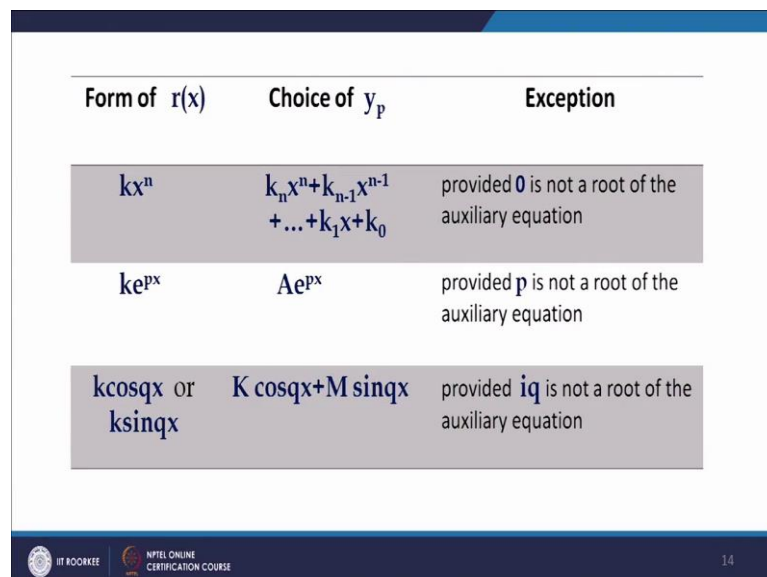

The general solution is therefore

$$y(x) = c_1 e^x + c_2 e^{4x} - \frac{8}{3} x e^x$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

(Refer Slide Time: 25:35)

Form of $r(x)$	Choice of y_p	Exception
kx^n	$k_n x^n + k_{n-1} x^{n-1} + \dots + k_1 x + k_0$	provided 0 is not a root of the auxiliary equation
ke^{px}	Ae^{px}	provided p is not a root of the auxiliary equation
$k \cos qx$ or $k \sin qx$	$K \cos qx + M \sin qx$	provided iq is not a root of the auxiliary equation

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

In this slide we have listed the choice of y p x depending on the choice of r x. So, if in the first column we have given the form of r x in the second column we have given the

choice of $y_p(x)$, provided we have these exceptions. So, suppose $r(x)$ is of the form kx^n to the power n , then where k is a constant. Then we shall make the choice of $y_p(x)$ to be a polynomial in x of degree n that is $k_n x^n + k_{n-1} x^{n-1} + \dots + k_1 x + k_0$. This will be the choice of $y_p(x)$, provided 0 is not a root of the auxiliary equation. If 0 is the root of the auxiliary equation what we have to do, we shall see next.

Now, in the next slide, when $r(x)$ is $k e^{px}$ to the power p , then we shall choose $y_p(x)$ to be $A e^{px}$ to the power p provided p is not a root of the auxiliary equation, like in the previous example we have seen that, $r(x)$ here the m equal to 1 m equal to m equal to was a root of the auxiliary equation. So, the choice of $A e^{px}$ did not was not a correct choice. So, so this is an exceptional case. So, when p is not root of the auxiliary equation, we will make a choice of our $y_p(x)$ as $A e^{px}$. If $r(x)$ is $k \cos qx$ or $k \sin qx$, then the choice of $y_p(x)$ will be taken as $k \cos qx + m \sin qx$, provided $i q$ is not a root of the auxiliary equation.

Now these are the exceptional cases. When 0 is a root of the auxiliary equation or $i q$ is the root of auxiliary equation, what choice of $y_p(x)$ we will have to make it is given in the next slide.

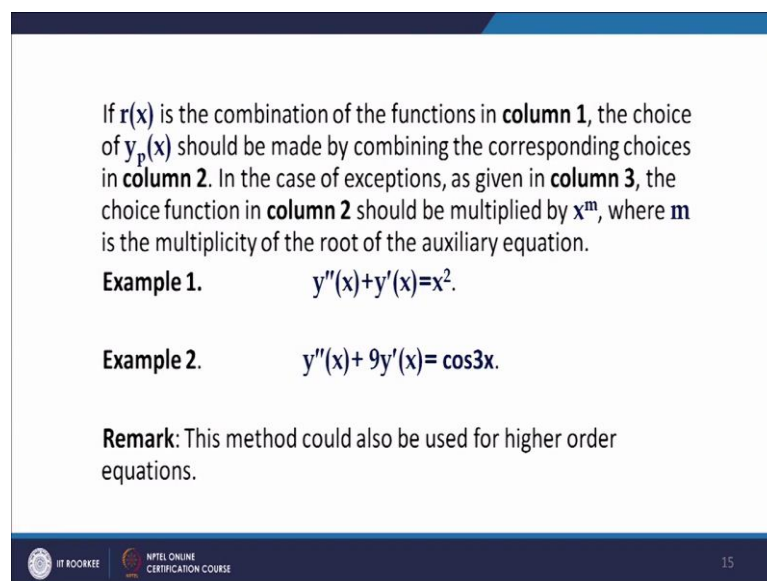

(Refer Slide Time: 27:39)

If $r(x)$ is the combination of the functions in **column 1**, the choice of $y_p(x)$ should be made by combining the corresponding choices in **column 2**. In the case of exceptions, as given in **column 3**, the choice function in **column 2** should be multiplied by x^m , where m is the multiplicity of the root of the auxiliary equation.

Example 1. $y''(x) + y'(x) = x^2.$

Example 2. $y''(x) + 9y'(x) = \cos 3x.$

Remark: This method could also be used for higher order equations.

The slide content is presented in a white box with a blue header and footer. The footer contains the logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, along with the page number 15.

So, here let us see if $r(x)$ is a combination of the functions in column 1, if $r(x)$ is the combination of functions given in the column 1, then the choice of $y_p(x)$ should be made

by combining the corresponding choices in column 2. In the case of exceptions as given in column 3, the choice function in column 2 should be multiplied by x to the power m . Let us see now we have seen that m equal to 1, p equal to 1 was a root of the auxiliary equation here, p equal to 1 was a root of the auxiliary equation here.

(Refer Slide Time: 28:20)

Example. $y'' - 5y' + 4y = 8e^x$.

The auxiliary equation is

$$m^2 - 5m + 4 = 0$$

$$m = 4, 1$$

So, $y_c(x) = c_1 e^x + c_2 e^{4x}$.

Further $r(x) = 8e^x$, so if we assume $y_p(x) = Ae^x$

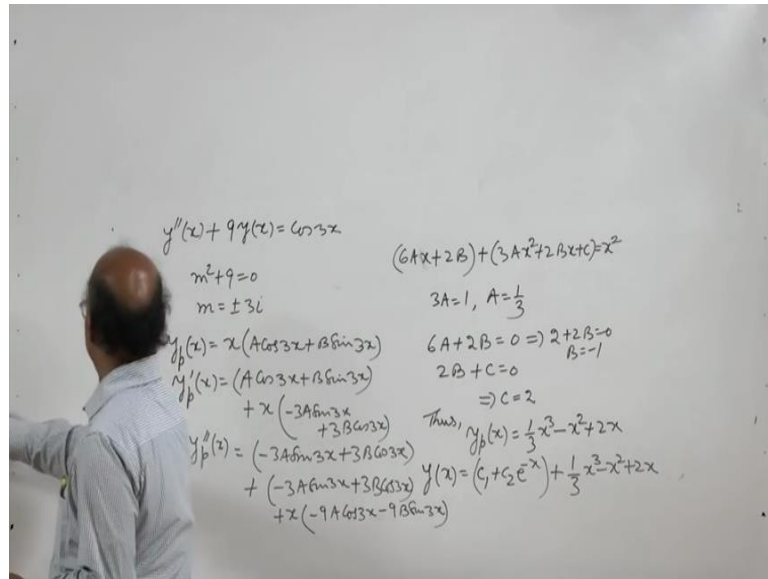

then $0 = 8e^x$

Thus, we have made a wrong guess for $y_p(x)$.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 11

So, we had to consider and it occurred once it is multiplicity is 1. So, we had to multiply e to the power x by x . We had to assume $y_p(x) = Ax e^x$. So, in the case of exceptions as given in column 3 the choice function column 2 should be multiplied by x to the power m , where m is the multiplicity of the root of the auxiliary equation.

(Refer Slide Time: 28:51)

Now, let us take the example $y'' + 9y = \cos 3x$. Let us see what do we how do we, choose $r(x)$, $y_p(x)$ here; so $y'' + 9y = \cos 3x$. So, auxiliary equation here is $m^2 + 9 = 0$. So, $m = 0$ and $\pm 3i$. And therefore, complimentary function $y_c(x)$ is equal to $C_1 e^{0x} + C_2 e^{2ix} + 2e^{-2ix}$. Or we can say $C_1 + C_2 e^{2ix} + 2e^{-2ix}$. Now let us look at the table 0 is a root of the auxiliary equation.

So, this is an exceptional case. So, in this case 0 occurs once and therefore, we have to multiply $y_p(x)$. So, the $y_p(x)$, because $r(x)$ is equal to x^2 here, $r(x)$ is given to be x^2 here. So, natural choice of $y_p(x)$ should have been $Ax^2 + Bx + C$, but in this exceptional case we will multiply $Ax^2 + Bx + C$ by x . Because 0 is the root of the auxiliary equation and it occurs once. So, we have to multiply the choice $Ax^2 + Bx + C$ by x with this choice of $y_p(x)$ when you when you substitute this $y_p(x)$ into the given differential equation, what you will have. So, these x^3 .

So, $3Ax^2 + 2Bx + C$ and then $y_p''(x)$ you will get as $6Ax + 2B$. So, let us put these values of $y_p(x)$ and the derivatives in the given differential equation. So, $6Ax + 2B + (3Ax^2 + 2Bx + C) = x^2$. So, what do we notice is that. So, we notice that the coefficient of x^2 is an identity it is true for all values of x . So, we should equate the corresponding powers of like powers of x . So, $3A = 1$. So,

we get a equal to $\frac{1}{3}$. Then we have to look at the coefficient of x here. So, $6a + 2B$ equal to 0 . Because there is no coefficient of x , there it is 0 and then we have $2B + C$ equal to 0 .

So, substituting a equal to $\frac{1}{3}$ here, this will give you $6a$ equal to 2 . $2 + 2B$ equal to 0 which will give you B equal to -1 . And B equal to -1 , then gives you C equal to 2 . So, thus $y_p(x)$ is equal to Ax^3 , A is equal to $\frac{1}{3}$. So, $\frac{1}{3}x^3$ and then Bx^2 Bx^2 means $-x^2$ and then we have Cx . So, $2x$. So, the general solution is $y(x) = y_c(x)$, $y_c(x)$ is $c_1 e^{-x} + c_2 e^{2x}$, e^{-x} to the power $-x$ this is $y_c(x) + y_p(x)$. So, this is the general solution of the given differential equation.

We can have one more example $y'' + 9y = \cos 3x$ which will take care of the other exceptional case. Where $i\sqrt{3}$ this exceptional case $i\sqrt{3}$ is not a root of the auxiliary equation. So, let us discuss now another example $y'' + 9y = \cos 3x$. In this case we have the auxiliary equation as $m^2 + 9 = 0$. So, $m = \pm 3i$.

Now this is an exceptional case, because in the $r(x)$ here is $\cos 3x$ and we see that $r(x)$ is equal to $\cos 3x$, and $i\sqrt{3}$ is a root of the auxiliary equation. So, what we see that $i\sqrt{3}$ occurs once here therefore, $y_p(x)$ will be assumed as $x(A \cos 3x + B \sin 3x)$. So, if you assume $y_p(x)$ to be equal to this, then $y_p'(x)$ will be equal to $A \cos 3x + B \sin 3x + x(-3A \sin 3x + 3B \cos 3x)$. And then $y_p''(x)$ will be equal to $-3A \sin 3x + 3B \cos 3x + x(-9A \cos 3x - 9B \sin 3x)$.

So, when you put these values in the given differential equation, let us see what we get. So, $y'' + 9y = \cos 3x$.

(Refer Slide Time: 35:12)

Now, this is minus 3 sin 3 x minus 3 A sin 3 x. So, minus 6 A sin 3 x and we get 3 B cos 3 B cos 3 x 6 B cos 3 x. And then x times minus 9 A cos 3 x minus 9 B sin 3 x. So, this is y p double dash plus 9 times y A y p x. So, y p x is x times A cos 3 x, plus B sin 3 x, equal to cos 3 x. Now 9 x into A cos 3 x will cancel with minus 9 A into x cos 3 x. 9 x B sin 3 x will cancel with minus 9 B sin 3 x.

So, this and this cancel now equating the coefficients of sin 3 x and cos 3 x both sides, we get a equal to 0 and B equal to 1 by 6. And therefore, y p x equal to x times a 0 B is 1 by 6. So, x by 6 sin 3 x. And thus, general solution y x is equal to y c x plus y p x, which is equal to now y c x here is some constant c 1 cos 3 x plus c 2 sin 3 x. So, this will be c 1 cos 3 x plus c 2 sin 3 x, plus x y 6, sin 3 x. So, this is how we shall solve this equation.

Now in my next lecture we shall discuss the general method for obtaining the general solution of second order no non homogenous linear differential equation.

Thank you.
