Lecture - 51
Parseval's Identity

Welcome on the lecture series on Mathematical Methods and its Applications. So, we were seeing Fourier series and what are various properties of Fourier series? That we have discussed in the last lectures. Now this is Parseval's identity. Now what Parseval identity is? And how it is important to solve few problems on Fourier series? Let us see.

(Refer Slide Time: 00:46)

The slide content is as follows:

Parseval's Identity

The Parseval's identity is given as

$$\int_{-\ell}^{\ell} (f(x))^2 dx = \ell \left\{ \frac{1}{2} a_0^2 + \sum_{n=1}^{\infty} (a_n^2 + b_n^2) \right\},$$

provided the Fourier series for $f(x)$ converges uniformly in $(-\ell, \ell)$.

At the bottom of the slide, there are logos for IIT Roorkee and NPTEL Online Certification Course, and a page number '2'.

Now, it states that the Parseval's identity is given by integral minus 1 to plus 1 f x whole square d x is given by l times a naught square by 2 plus summation a n square b n square, provided Fourier series converges uniformly in minus 1 to 1. Now what is the proof of this identity?

(Refer Slide Time: 01:07)

$$\begin{aligned}
 f(x) &= \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi x}{l} + \sum_{n=1}^{\infty} b_n \sin \frac{n\pi x}{l} \\
 \int_{-l}^l (f(x))^2 dx &= \frac{a_0}{2} \int_{-l}^l f(x) dx + \sum_{n=1}^{\infty} a_n \left(\int_{-l}^l f(x) \cos \frac{2n\pi x}{l} dx \right) + \sum_{n=1}^{\infty} b_n \left(\int_{-l}^l f(x) \sin \frac{2n\pi x}{l} dx \right) \\
 &= \frac{a_0}{2} (l a_0) + \sum_{n=1}^{\infty} a_n (l a_n) + \sum_{n=1}^{\infty} b_n (l b_n) \\
 &= l \frac{a_0^2}{2} + l \sum_{n=1}^{\infty} a_n^2 + l \sum_{n=1}^{\infty} b_n^2 \\
 &= l \left[\frac{a_0^2}{2} + \sum_{n=1}^{\infty} (a_n^2 + b_n^2) \right]
 \end{aligned}$$

$$\begin{aligned}
 a_0 &= \frac{1}{l} \int_{-l}^l f(x) dx \\
 a_n &= \frac{1}{l} \int_{-l}^l f(x) \cos \frac{n\pi x}{l} dx \\
 b_n &= \frac{1}{l} \int_{-l}^l f(x) \sin \frac{n\pi x}{l} dx
 \end{aligned}$$

Now, what is the Fourier series? Expansion of $f(x)$, we know that Fourier series expansion of $f(x)$ is nothing but it is a naught upon 2 plus summation n varying from 1 to infinity $a_n \cos \frac{n\pi x}{l}$ plus summation n varying from 1 to infinity $b_n \sin \frac{n\pi x}{l}$. So, this is how we can expand the function in terms of sin and cosine terms. Now we want to find out in minus 1 to 1 integral, integral minus 1 to 1 $f(x)^2 dx$. So, you simply multiply both sides by $f(x)$ and integrate from minus 1 to plus 1.

So, what we will get? Integral minus 1 to 1 $f(x)^2 dx$ from this side it is nothing a naught upon 2 integral minus 1 to plus 1 $f(x) dx$ plus summation n varying from 1 to infinity a_n because x is only here. So, it is integral minus 1 to plus 1 $f(x) \cos \frac{n\pi x}{l} dx$; this term plus summation n varying from 1 to infinity b_n and integral from minus 1 to plus 1 $f(x) \sin \frac{n\pi x}{l} dx$.

Now if you recall the formulas of a_n and b_n . Now what is a naught? We already know that a naught is nothing but $\frac{1}{l} \int_{-l}^l f(x) dx$, a_n is nothing but $\frac{1}{l} \int_{-l}^l f(x) \cos \frac{n\pi x}{l} dx$ and b_n is nothing but $\frac{1}{l} \int_{-l}^l f(x) \sin \frac{n\pi x}{l} dx$. This we already know. So, what this value is? Integral minus 1 to plus 1 $f(x) dx$, this is nothing but a naught into l . So, this value is nothing but a naught into l plus summation n from 1 to infinity a_n .

Now, this value integral minus 1 to plus 1 of $f(x) \cos n\pi x$ by dx is nothing but a_n into l . So, this is nothing but l into a_n plus summation n varying from 1 to infinity, similarly this value is nothing but b_n into l . So, this is nothing but l into b_n . So, hence this expression will be nothing but l into a_n^2 plus l into b_n^2 plus l times summation n from 1 to infinity a_n^2 plus l times summation n from 1 to infinity b_n^2 . So, this can be rewritten as, l we can take common a_n^2 plus b_n^2 upon 2 plus summation n varying from 1 to infinity a_n^2 plus b_n^2 . So, this identity is called Parseval's identity.

(Refer Slide Time: 04:52)

Corollary 1
 If the half-range cosine series for the function $f(x)$ in $(0, l)$ is

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{l}\right),$$

then the Parseval's formula is given as

$$\int_0^l (f(x))^2 dx = \frac{l}{2} \left(\frac{a_0^2}{2} + a_1^2 + a_2^2 + a_3^2 + \dots \right)$$

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 3

Now, so if we have half range series, which we have discussed in the last lecture; half range Fourier sin or cosine series. Half range cosine series of the function $f(x)$ in the interval 0 to l . So, that can also be using Parseval formula that can also be derived basically, what was Fourier cosine series? If we have a half range, so and we want a even extension of the function, even periodic function that is in the terms of cosine series, cosine terms.

(Refer Slide Time: 05:27)

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi x}{l}$$

$$\int_0^l (f(x))^2 dx = \int_0^l f(x) dx + \sum_{n=1}^{\infty} a_n \int_0^l f(x) \cos \frac{n\pi x}{l} dx$$

$$= \frac{a_0}{2} \left(\frac{a_0 l}{2} \right) + \sum_{n=1}^{\infty} a_n \left(\frac{l a_n}{2} \right)$$

$$= \frac{l}{2} \left[\frac{a_0^2}{2} + \sum_{n=1}^{\infty} a_n^2 \right]$$

$$a_0 = \frac{2}{l} \int_0^l f(x) dx$$

$$a_n = \frac{2}{l} \int_0^l f(x) \cos \frac{n\pi x}{l} dx$$

So, what is the expansion of that function? It is nothing but $f(x)$ equals to $\frac{a_0}{2}$ plus summation n varying from 1 to infinity $a_n \cos n\pi x$ by l . This is how we can write down the function $f(x)$ in terms of cos. We take the even extension of the function. So, what is a_0 here, a_0 is nothing; upon 2 upon l integral 0 to l $f(x) dx$ and what is a_n ? a_n is again 2 upon l integral 0 to l $f(x) \cos n\pi x$ upon l into dx .

So, again we multiply both sides by $f(x)$ integrate from $-l$ to l , so what we will obtain? Integral $-l$ to l $f(x) dx$, $f(x)^2 dx$ is nothing but $\frac{a_0^2}{2}$ upon 2 integral $-l$ to l $f(x) dx$ plus summation n from 1 to infinity a_n integral $-l$ to l $f(x) \cos n\pi x$ upon l into dx . Now this is $\frac{a_0^2}{2}$ upon 2 , now this value it is from 0 to l ; it is from 0 to l . It is not from $-l$ to l because it is half range. So, it is from 0 to l . So, integrate from 0 to l . Now 0 to l this integral is nothing but $\frac{a_0 l}{2}$ upon 2 . So, it is $\frac{a_0 l}{2}$ upon 2 plus summation n from 1 to infinity; it is a_n . It is again l into a_n upon 2 .

So, this is nothing but you can take l by 2 common and it is nothing but $\frac{a_0^2}{2}$ square upon 2 plus summation n from 1 to infinity a_n^2 . So, which is same expression l by 2 , a_n^2 raised to l square by 2 plus summation n square n from 1 to infinity. So, this is how the Parseval identity can be used, when we have a half range cosine series. Similarly, if we have a Fourier, if we have a half range sin series, that is we extend the function considering function as an odd function.

(Refer Slide Time: 07:58)

Corollary 2
If the half-range sine series for the function $f(x)$ in $(0, \ell)$ is

$$f(x) = \sum_{n=1}^{\infty} b_n \sin\left(\frac{n\pi x}{\ell}\right),$$

then the Parseval's formula is given as

$$\int_0^{\ell} (f(x))^2 dx = \frac{\ell}{2} (b_1^2 + b_2^2 + b_3^2 + \dots)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Then Fourier expansion is given by $f(x) = \sum_{n=1}^{\infty} b_n \sin \frac{n\pi x}{\ell}$ and using Parseval identity or the formula we will obtain $\int_0^{\ell} f(x)^2 dx = \frac{\ell}{2} \sum_{n=1}^{\infty} b_n^2$. So, that can also be derived using the same lines, this formula can also be derived.

(Refer Slide Time: 08:22)

Root mean square value
The root mean square (rms) value of the function $f(x)$ in an interval (a, b) is defined by

$$[f(x)]_{rms} = \sqrt{\frac{\int_a^b [f(x)]^2 dx}{b-a}}$$

It is also known as the effective value of the function.
It has applications in the theory of mechanical vibrations and in electric circuit theory.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

Now, next is root mean square value. The root mean square value of the function $f(x)$ in the interval a to b is given by $[f(x)]_{rms} = \sqrt{\frac{\int_a^b f(x)^2 dx}{b-a}}$. Under root of the entire expression, it is also known as the

effective value of the function and it has application in theory of mechanical vibrations and in electrical circuits' theory, this root mean square value. Now let us solve few problems based on Parseval identity.

(Refer Slide Time: 08:49)

Problem

Apply Parseval's identity to the function

$$f(x) = x, \quad -\pi \leq x \leq \pi, \quad f(x+2\pi) = f(x),$$

and hence deduce that

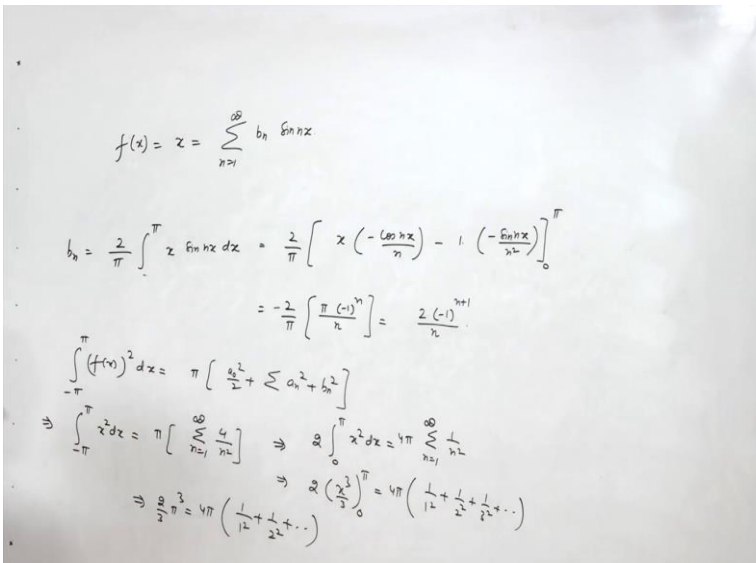

$$\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \dots + \frac{1}{n^2} + \dots = \frac{\pi^2}{6}.$$

6

Now, apply Parseval identity to the function this and deduce that this equal to this. So, this series we have to find out using Parseval identity.

So, now $f(x) = x$ is an odd function, $f(x) = x$ from minus π to plus π is an odd function. It will contain only sin terms, sin series a naught and a_n are 0.

(Refer Slide Time: 09:15)

$$f(x) = x = \sum_{n=1}^{\infty} b_n \sin nx$$

$$b_n = \frac{2}{\pi} \int_{-\pi}^{\pi} x \sin nx \, dx = \frac{2}{\pi} \left[x \left(-\frac{\cos nx}{n} \right) - \int \left(-\frac{\sin nx}{n} \right) dx \right]_0^{\pi}$$

$$= -\frac{2}{\pi} \left[\frac{\pi (-1)^n}{n} \right] = \frac{2 (-1)^{n+1}}{n}$$

$$\int_{-\pi}^{\pi} (f(x))^2 \, dx = \pi \left[\frac{a_0^2}{2} + \sum_{n=1}^{\infty} (a_n^2 + b_n^2) \right]$$

$$\Rightarrow \int_{-\pi}^{\pi} x^2 \, dx = \pi \left[\sum_{n=1}^{\infty} \left(\frac{2}{n} \right)^2 \right] \Rightarrow \int_0^{\pi} x^2 \, dx = 4\pi \sum_{n=1}^{\infty} \frac{1}{n^2}$$

$$\Rightarrow \frac{2}{3} \pi^3 = 4\pi \left(\frac{1}{1^2} + \frac{1}{2^2} + \dots \right)$$

So, the $f(x)$ which is equal to x will be nothing but $\sum_{n=1}^{\infty} b_n \sin nx$ because l is π . So, what will be b_n ? b_n will be given by $\frac{2}{\pi} \int_0^{\pi} x \sin nx \, dx$, $f(x) \sin nx$ by l into dx . Now you integrate this, it is $\frac{2}{\pi}$ first as it is integration of second which is $-\cos nx$ upon n minus derivative of first into integration of second and 0 to π .

So, applying integration by parts, we obtain this. Now we take the limits, it is $\frac{2}{\pi}$ negative will come outside. It is 0 , when x is π or 0 and when x is π it is nothing but π into $-\frac{1}{n}$ to power n upon n and when x is 0 , it is 0 . So, it is nothing but $\frac{2}{\pi} \left[-\frac{\cos nx}{n} + x \frac{\sin nx}{n} \right]_0^{\pi}$. So, this will be b_n . Now what is Parseval's identity? It is integration from $-\pi$ to π , $f(x)^2 dx$ will be equal to l times, l is π here π times a_0^2 upon 2 plus $\sum_{n=1}^{\infty} (a_n^2 + b_n^2)$. So, this is basically Parseval's identity. So, this is equal to, now this implies $-\pi$ to π this is $x^2 dx$ this is equal to x^3 because $f(x)$ is x and π a naught is 0 , a_n is 0 only b_n is here and b_n value is this when you square this it is $\sum_{n=1}^{\infty} b_n^2$. It is $\frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1}{n^2}$, when you take b_n^2 .

So, this implies, now it is an even function it is nothing but $2 \int_0^{\pi} x^2 dx$ which is equal to $\frac{2}{3} x^3$ from 0 to π will come out, $\sum_{n=1}^{\infty} \frac{1}{n^2}$ from 1 to infinity. So, this further implies $\frac{2}{3} \pi^3$ from 0 to π and it is $\frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1}{n^2}$. It is 1 by 1^2 plus 1 by 2^2 plus 1 by 3^2 and so on. So, this implies $\frac{2}{3} \pi^3$ is equal to $\frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1}{n^2}$ into this expression. So, therefore, this value is nothing but when you simplify this it is nothing but $\frac{\pi^2}{6}$ when you simplify this. So, this expression is nothing but $\frac{\pi^2}{6}$. So, hence using Parseval identity, we can easily find out the value of the series.

(Refer Slide Time: 13:07)

Problem

Using Parseval's identity to the function

$$f(x) = x^2, \quad -\pi \leq x \leq \pi, \quad f(x + 2\pi) = f(x),$$

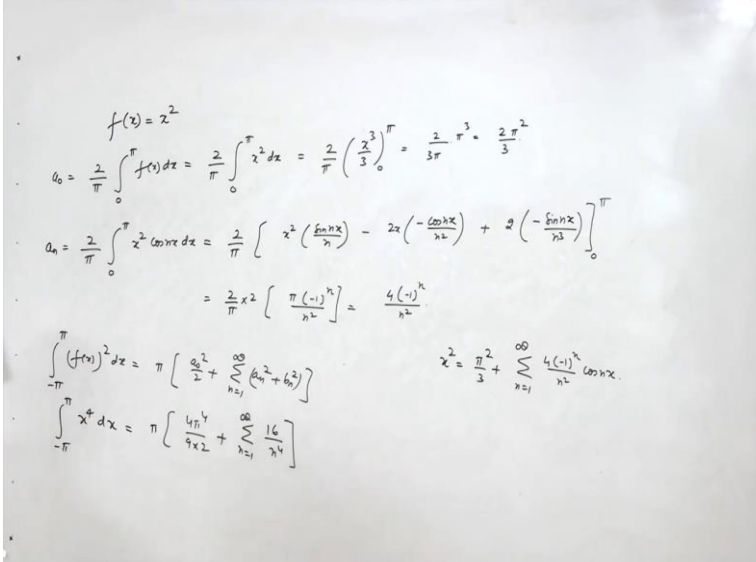

show that

$$\frac{1}{1^4} + \frac{1}{2^4} + \frac{1}{3^4} + \frac{1}{4^4} + \dots = \frac{\pi^4}{90}.$$

Now, the next problem is $f(x)$ equal to x square, it is an even function and when we apply Parseval identity for this problem, it is an even function; that means, it will contain only cosine terms. So, b_n will be 0.

(Refer Slide Time: 13:16)

$f(x) = x^2$
 $a_0 = \frac{2}{\pi} \int_0^{\pi} f(x) dx = \frac{2}{\pi} \int_0^{\pi} x^2 dx = \frac{2}{\pi} \left(\frac{x^3}{3} \right)_0^{\pi} = \frac{2}{3\pi} \pi^3 = \frac{2\pi^2}{3}$
 $a_n = \frac{2}{\pi} \int_0^{\pi} x^2 \cos nx dx = \frac{2}{\pi} \left[x^2 \left(\frac{\sin nx}{n} \right) - 2x \left(-\frac{\cos nx}{n^2} \right) + 2 \left(\frac{-\sin nx}{n^3} \right) \right]_0^{\pi}$
 $= \frac{2}{\pi} x^2 \left[\frac{\pi (-1)^{n^2}}{n^2} \right] = \frac{4(-1)^n}{n^2}$
 $\int_{-\pi}^{\pi} (f(x))^2 dx = \pi \left[\frac{a_0^2}{2} + \sum_{n=1}^{\infty} (a_n^2 + b_n^2) \right]$
 $\int_{-\pi}^{\pi} x^4 dx = \pi \left[\frac{4\pi^4}{9 \times 2} + \sum_{n=1}^{\infty} \frac{16}{n^4} \right]$
 $x^2 = \frac{\pi^2}{3} + \sum_{n=1}^{\infty} \frac{4(-1)^n}{n^2} \cos nx$

So, what will be function $f(x)$? $f(x)$ is x square. So, first let us compute a naught, a naught will be nothing but $\frac{2}{\pi}$ upon π integral 0 to π $f(x) dx$ which is nothing but $\frac{2}{\pi}$ upon π integral 0 to π x square dx which is equals to $\frac{2}{\pi}$ upon π , integration is x cube by 3 from 0 to π . So, it is $\frac{2}{\pi}$ upon 3π into π cube, which is $\frac{2\pi^2}{3}$ upon 3 . So, this is a naught.

Now, a n is 2 upon pi integral 0 to pi, f x cos n x d x. Now you integrate by parts, it is 2 upon pi, it is x square sin n x upon n minus 2 x minus cos n x upon n square minus minus plus 2 into minus sin n x upon n cube from 0 to pi. Now sin terms will be 0, when x is 0 or x is pi. So, only this term is remaining and it is also 0, when x is 0. So, it is nothing but 2 upon pi, 2 this will also come out and it is nothing but pi into minus 1 to power n upon n square. So, this is nothing but 4 into minus 1 to power n upon n square. So, this will be a n.

So, we can easily find out the Fourier series of this f x, which is nothing but we already know it is nothing but x square is nothing but a naught upon 2, that is pi square upon 3 plus summation n from 1 to infinity; a n is this value which is 4 minus 1 to power n upon n square into cos n x. So, this will be the Fourier series of this function x square. Now if we apply Parseval identity for this problem. So, what will be that? It will be minus pi to pi f x whole square d x will be equals to 1 times a naught square upon 2 plus summation a n square plus b n square, n varying from 1 to infinity.

Now, this b n is 0 because it is an even function. So, this is nothing but minus pi to plus pi x to power 4 d x and it is pi times a naught square upon 2, a naught square is 4 pi to power 4 upon 9 into 2 plus n square, n square is 16 upon n to power 4; n is varying from 1 to infinity. Now when you simplify this, what we will get?

(Refer Slide Time: 16:45)

$$2 \left[\frac{x^2}{5} \right]_0^\pi = \frac{2\pi^2}{9} + 16\pi \sum \frac{1}{n^4}$$

$$\frac{2\pi^2}{5} - \frac{2\pi^2}{9} = 16\pi \sum \frac{1}{n^4}$$

$$\Rightarrow 2\pi^2 \left(\frac{2}{45} \right) = 16\pi \sum \frac{1}{n^4} \Rightarrow \frac{\pi^4}{90} = \sum \frac{1}{n^4}$$

$$\int_{-\pi}^{\pi} (f(x))^2 dx = \pi \left[\frac{a_0^2}{2} + \sum_{n=1}^{\infty} (a_n^2 + b_n^2) \right]$$

$$\int_{-\pi}^{\pi} x^4 dx = \pi \left[\frac{4\pi^4}{4 \times 2} + \sum_{n=1}^{\infty} \frac{16}{n^4} \right]$$

So now using Parseval identity in this expression we obtain this, now if you simplify this, this is an even function; it is 2 times x to power 5 upon 5 from 0 to pi, which is equal to, it is 2 pi to power 5 upon 9 plus 16 pi into summation 1 by n to power 4.

Now, this is nothing but 2 upon 5 pi to power 5 minus 2 upon 9 pi to power 5, which is equals to 16 pi into summation 1 by n to power 4. So, this implies, it is 2 upon, 2 this is common. So, it is nothing but 4 upon 45, which is equals to 16 pi into summation 1 by n to power 4. So, this implies it is nothing but pi to power 4 upon 90 will be equals to summation 1 by n to power 4. So, hence we have proved this, that summation one by n to power 4 is nothing but pi k to power 4 upon 90. So, this is how we can apply Parseval identity in this problem, to solve this equation.

(Refer Slide Time: 18:12)

Problem

For the function, $f(x) = x + x^2$, $-\pi \leq x \leq \pi$, $f(x + 2\pi) = f(x)$, apply Parseval's identity to evaluate the value of

$$\sum_{n=1}^{\infty} \left(\frac{4}{n^4} + \frac{1}{n^2} \right).$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

Now, let us try one more problem, which is neither even nor odd. It is x plus x square and we have to apply Parseval identity to find out the value of this expression. So, again we can apply Parseval identity in this problem. Let us see.

(Refer Slide Time: 18:29)

$$\begin{aligned}
 f(x) &= x + x^2 \\
 a_0 &= \frac{1}{\pi} \int_{-\pi}^{\pi} (x + x^2) dx = \frac{2}{\pi} \int_0^{\pi} x^2 dx = \frac{2}{\pi} \left(\frac{x^3}{3} \right)_0^{\pi} \\
 &= \frac{2}{3\pi} \pi^3 = \frac{2\pi^2}{3} \\
 a_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} (x + x^2) \cos nx dx = \frac{2}{\pi} \int_0^{\pi} x^2 \cos nx dx \\
 &= \frac{2}{\pi} \left[x^2 \left(\frac{\sin nx}{n} \right) - 2x \left(-\frac{\cos nx}{n^2} \right) + 2 \left(-\frac{\sin nx}{n^3} \right) \right]_0^{\pi} \\
 &= \frac{4\pi}{\pi n^2} [(-1)^n] - \frac{4}{n^2} (-1)^n \\
 b_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} (x + x^2) \sin nx dx = \frac{2}{\pi} \int_0^{\pi} x \sin nx dx = \frac{2}{\pi} \left[x \left(-\frac{\cos nx}{n} \right) - 1 \left(-\frac{\sin nx}{n^2} \right) \right]_0^{\pi} \\
 &= -\frac{2\pi}{\pi n} [(-1)^n] = -\frac{2}{n} (-1)^{n+1}
 \end{aligned}$$

So, what will be $f(x)$? What is $f(x)$? $f(x)$ is x plus x square. So, it will contain all terms sine terms, cosine terms it will contain all the terms. So, we have to find a constant a_n and b_n . So, what will be a constant? a constant will be nothing but $\frac{1}{\pi} \int_{-\pi}^{\pi} (x + x^2) dx$. So, this x is an odd function. So, this integral will be 0, only this will be left. So, it is $\frac{2}{\pi} \int_0^{\pi} x^2 dx$.

So, this is nothing but $x^2 dx$. So, it is nothing but $\frac{2}{\pi} \int_0^{\pi} x^2 dx$, it is x^3 upon 3; 0 to π , which is equals to $\frac{2}{\pi} \int_0^{\pi} x^2 dx$, which is $\frac{2}{\pi} \left(\frac{x^3}{3} \right)_0^{\pi}$, which is $\frac{2}{3\pi} \pi^3$, which is $\frac{2\pi^2}{3}$. So, this is a constant. Now what will be a_n ? a_n is $\frac{1}{\pi} \int_{-\pi}^{\pi} (x + x^2) \cos nx dx$. Now $x \cos nx$ is an odd function with respect to x it is 0 and $x^2 \cos nx$ is an even function. So it will be $\frac{2}{\pi} \int_0^{\pi} x^2 \cos nx dx$.

Again we will apply integration by parts to solve this. It is $\frac{2}{\pi} \int_0^{\pi} x^2 \cos nx dx$ integration of this is $\frac{\sin nx}{n}$ minus derivative of this, integration of this plus 2 integration of this from 0 to π . So, only one term is left which is nothing but $\frac{4}{\pi n^2} [(-1)^n]$ and it is nothing but when x is π , so it is π times minus 1 to power n . It is $\frac{4}{\pi n^2} [(-1)^n]$, π cancels out; it is $\frac{4}{n^2} [(-1)^n]$. So, this will be a_n .

Now, let us compute b_n , b_n is nothing but $\frac{1}{\pi} \int_{-\pi}^{\pi} (x + x^2) \sin nx dx$, x plus x square sorry it is $f(x)$ plus x square, so it is x plus x square. Now $x \sin nx$ is an even function and $x^2 \sin nx$ is an odd function. So $x^2 \sin nx$ will

be 0, it will be 2 upon pi integral 0 to pi x sin n x. So, again we will apply integration by parts here. So it is nothing but 2 upon pi x into minus cos n x upon n minus derivative of first integration of second minus sin n x upon n square and it is from 0 to pi. So, it is nothing but 1 upon pi minus will come out, n will come out and it is nothing but pi times minus 1 to power n. So, pi, pi cancel out it is nothing but 2 upon n minus 1 to power n plus 1. So, this expression will be here.

So, we got the values of a naught a n and b n. We can directly apply Parseval identity to find out the value of this expression. So, what is Parseval identity now? So, let us note down the values of a naught, a naught we obtained 2 pi upon square upon 3, a n we obtained as 4 upon n square minus 1 to power n and b n we obtained as 2 upon n minus 1 to power n plus 1. So, these values we have obtained, now we can apply Parseval's identity.

(Refer Slide Time: 22:32)

The image shows handwritten mathematical work on a whiteboard. It includes the following equations:

$$\int_{-\pi}^{\pi} (x+x^2)^2 dx = \pi \left[\frac{4x^4}{9} + \sum \left(\frac{4}{n^4} + \frac{4}{n^2} \right) \right]$$

$$\Rightarrow \int_{-\pi}^{\pi} (x^2 + 2x^3 + x^4) dx = \frac{2\pi^5}{9} + 4\pi \sum \left(\frac{4}{n^4} + \frac{1}{n^2} \right)$$

$$2 \left[\frac{x^3}{3} + \frac{2x^5}{5} \right]_{-\pi}^{\pi} = \frac{2\pi^5}{9} + 4\pi \sum \left(\frac{4}{n^4} + \frac{1}{n^2} \right)$$

$$\Rightarrow \left(2 \left[\frac{\pi^3}{3} + \frac{2\pi^5}{5} \right] - \frac{2\pi^5}{9} \right) \frac{1}{4\pi} = \sum \left(\frac{4}{n^4} + \frac{1}{n^2} \right)$$

On the right side of the whiteboard, the Fourier coefficients are listed:

$$a_0 = \frac{2\pi^2}{3}$$

$$a_n = \frac{4}{n^2} (-1)^n$$

$$b_n = \frac{2}{n} (-1)^{n+1}$$

So, this is integral minus 1 to plus 1, f x square; f x whole square d x which is equals to 1 into a naught square upon 2, that is 4 pi to power 4 upon 9 into 2 plus summation; summation a n square, that is 16 upon n to power 4 plus b n square 4 upon n square.

So, this implies. So, first we simplify this. So, this integral is nothing but minus pi to pi, it is x square plus x to power 4 plus 2 x cube whole into d x plus it is which is equal to it is 2 pi to power 5 upon 9 plus 4 pi and summation 4 upon n to power 4 plus 1 by n

square. So, this is the required expression which you want to find out, required expression. So we can easily simplify now. It is an even function and odd function.

So, this will be 0 and it is 2 times it is x^3 upon $3 + x^5$ upon 5 from 0 to π and it is equal to $2\pi^5$ plus $9\pi^4$ into summation 4 upon n to power 4 plus 1 by n^2 . So, this implies 2 into it is π^3 by $3 + \pi^5$ by 5 minus $2\pi^5$ upon 9 and whole divided by 1 upon 4π I mean 4π is equal to summation 4 upon n^2 plus 1 upon here, $4 + 1$ upon n^2 . So, we can simplify this value, on simplify we will get the value of this expression.

So, this is how one can apply a Parseval identity to find out the value of some series expansion, using Fourier transforms, using Fourier series sorry.

Thank you very much.
