Lecture - 59
Applications of Fourier transforms to BVP – II

So, welcome to the lecture series on Mathematical Methods and the Applications. So, in the last lecture we have deal applications of Fourier series that how Fourier series we can apply to boundary value problems. Now in this lecture we will see applications of Fourier integrals and Fourier transforms. However, the main heading is applications to Fourier transforms, but in this we will see applications of Fourier series, Fourier transforms and Fourier integrals.

Now, take this equation Heat Equation this is a use of Fourier integrals, consider heat equation this.

(Refer Slide Time: 00:59)

Heat Equation: Use of Fourier Integrals

Consider the heat equation

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}, \quad (1)$$

in a bar that extends to infinity on both sides.
In this case, we do not have any boundary conditions, but only the initial condition

$$u(x, 0) = f(x), \quad -\infty < x < \infty,$$

where $f(x)$ is the given initial temperature of the bar.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

Now, the heat equation is given by $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$. Suppose this is the heat equation.

(Refer Slide Time: 01:04)

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2} \quad u(x,0) = f(x), \quad -\infty < x < \infty.$$

$$u(x,t) = F(x) G(t)$$

$$\frac{\partial u}{\partial t} = F(x) G'(t)$$

$$\frac{\partial^2 u}{\partial x^2} = F''(x) G(t)$$

$$F(x) G'(t) = c^2 F''(x) G(t) \Rightarrow \frac{F''}{F} = \frac{1}{c^2} \frac{G'}{G} = K.$$

$$K = -\beta^2, \quad F'' = -\beta^2 F \Rightarrow F'' + \beta^2 F = 0 \Rightarrow F = c_1 \cos \beta x + c_2 \sin \beta x.$$

$$G' = -\beta^2 c^2 G \Rightarrow G = k e^{-\beta^2 c^2 t}$$

$$u(x,t;p) = e^{-\beta^2 c^2 t} (c_1 \cos \beta x + c_2 \sin \beta x)$$

$$u(x,t) = \int_0^{\infty} e^{-\beta^2 c^2 t} (c_1 \cos \beta x + c_2 \sin \beta x) d\beta$$

$$= \int_0^{\infty} e^{-\beta^2 c^2 t} (c_1(\beta) \cos \beta x + c_2(\beta) \sin \beta x) d\beta.$$

$$u(x,0) = f(x)$$

$$\Rightarrow f(x) = \int_0^{\infty} (c_1(\beta) \cos \beta x + c_2(\beta) \sin \beta x) d\beta.$$

where

$$c_1(\beta) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \cos \beta x dx$$

$$c_2(\beta) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \sin \beta x dx.$$

Now this is a bar which extend both to infinite on both the sides, that is bar is not of finite length it is tends to infinite from both the sides. Now in this case we do not have any boundary conditions like we have in finite bar when we have x from 0 to 1, in that case we have a boundary condition, but when the bar is tending to infinite from both the sides we do not have any boundary conditions. However, we have the initial condition which is given by $u(x,0)$ is equal to $f(x)$ and of course, x varying from minus infinity to plus infinity ok. So, here $f(x)$ is a given initial temperature of the bar.

Now if you want to solve this problem, if you want to solve this problem here it is an infinite bar. So, how can we proceed again we will use separation of variables. So, we will take u which is function of x and t as $F(x) G(t)$. So, what will be $\frac{\partial u}{\partial t}$? It will be nothing, but $F(x) G'(t)$ and $\frac{\partial^2 u}{\partial x^2}$ will be nothing but $F''(x) G(t)$. So, when we substitute these 2 in this equation we will get $F''(x) G(t) = c^2 F(x) G'(t)$. So, when we divide both sides by $F(x) G(t)$, it is left hand side we have $\frac{F''(x)}{F(x)} = c^2 \frac{G'(t)}{G(t)}$. So, this implies $\frac{F''(x)}{F(x)}$ will be $\frac{1}{c^2} \frac{G'(t)}{G(t)}$. Now, again this is a function of x only $\frac{F''(x)}{F(x)}$ is a function of x only and this is a function of t only and both are equal. So, both are equal only when it is a constant quantity. So, it is equal to K .

Again, as we did in the previous lectures when k is 0 or k is p^2 . So, we discard both the cases because if suppose here we do not have any boundary condition still if K is a positive quantity. So, F will be nothing, but $c_1 e^{kx} + c_2 e^{-kx}$ which will tend to infinity as x tends to, as x increases, which does not have any practical significance. You see that if you take K equal to p^2 suppose and F'' will be nothing, but F'' will be nothing, but $p^2 f$. So, this will be nothing F from here we get $e^{kx} + c_2 e^{-kx}$ and s as x increases, so this increase exponentially because of the presence of this term. So, this has no any, does not have any practical significance. So, we discard the 2 cases when k is 0 or k is equal to p^2 . So, we take K equal to $-p^2$.

So, if K equal to $-p^2$. So, F'' will be nothing, but $-p^2 f$ which implies $F'' + p^2 f = 0$ and this implies F will be nothing, but $c_1 \cos px + c_2 \sin px$; $c_1 \cos px$ and $c_2 \sin px$. And g will be nothing, but from this condition g'' will be nothing but it is $-p^2 c^2$. So, this implies g will be nothing, but some K times $e^{Kt} - p^2 c^2 t$ because when we integrate both the sides we will get G equal to this.

So, what will be u ? So, $u \times t$ will be nothing but the product of these 2 this is nothing, but $e^{kx} - p^2 c^2 t$ into $c_1 \cos px + c_2 \sin px$. This is not; this is $u \times t$, this is $u \times t$ with a variables p . So, we write it like this with a variables p . So, we obtain $u \times t$ like this.

Now since it is an infinite bar x is varying from minus infinity to plus infinity. So, the solution $u \times$ can be obtained and p is positive quantity. So, $u \times t$ can be obtained by integrating all the terms 0 to infinite it is $e^{kx} - p^2 c^2 t$ and it is $c_1 \cos px + c_2 \sin px$ into dp . Now this $c_1 c_2$ are arbitrary constants here. So, we can take them as a function of p also. So, this $c_1 c_2$ we can take as a function of p . So, this is integral 0 to infinite $e^{kx} - p^2 c^2 t$ and this is c_1 some function of $p \cos px + c_2$ some function of $p \sin px$ whole with dp . This K will merge with when we take a part of these 2 this K will merge with c_1 and c_2 . So, there is no need of writing K in this expression.

Now, $u \times 0$ is given as $f \times$, so this implies $f \times$ will be equal to. So, 0 to infinity $c_1 p \cos px$ because substitute t equal to 0 here plus $c_2 p \sin px$ whole with dp . So, this is for a

integral, and $c_1 p$ and $c_2 p$ can be obtained by where $c_1 p$ and $c_2 p$ are nothing but; so, $c_1 p$ is nothing, but it will be $c_1 p$ will be given by minus infinity plus infinity; minus plus infinite $f(x) \cos px$ into dx it is 1 by π times I think it is 1 by π times and $c_2 p$ will be nothing but again 1 by π times minus infinity to plus infinity $f(x) \sin px$ into dp .

So, let us verify it 1 by π or what. So, we can simplify like this $f(x)$ is obtained like this and f^2 and $G(t)$ is nothing, but this expression.

(Refer Slide Time: 09:02)

Continued...

In order to solve the problem (1), let $u(x, t) = F(x)G(t)$. Then (1) gives two ordinary differential equations:

$$F'' + p^2 F = 0$$

and

$$G' + c^2 p^2 G = 0.$$

[We choose $k = -p^2$, because positive values of k would lead to an increasing exponential function which has no physical meaning].

Solutions are

$$F(x) = A \cos px + B \sin px, \text{ and } G(t) = e^{-c^2 p^2 t}.$$

3

So, when we put it here and integrate over this we obtain this thing. Now $u(x, 0)$ is this thing it is. So, $a p$ and $b p$ here it is $c_1 p$ and $c_2 p$. So, $c_1 p$ is this expression and $c_2 p$ is this expression which we obtained here also the same thing. Now we substitute back to this expressions in this $u(x, t)$. So, what we will obtain?

(Refer Slide Time: 09:37)

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2} \quad u(x,0) = f(x), \quad -\infty < x < \infty.$$

$$u(x,t) = \frac{1}{\pi} \int_0^{\infty} \left(e^{-p^2 c^2 t} \left[\int_{-\infty}^{\infty} f(\xi) \cos p \xi \cos p x \, d\xi \right] + e^{-p^2 c^2 t} \left[\int_{-\infty}^{\infty} f(\xi) \sin p \xi \sin p x \, d\xi \right] \right) dp.$$

$$= \frac{1}{\pi} \int_0^{\infty} e^{-p^2 c^2 t} f(\xi) \cos p(\xi - x) \, d\xi \, dp.$$

$$u(x,0) = f(x)$$

$$\Rightarrow f(x) = \int_0^{\infty} (c_1(p) \cos p x + c_2(p) \sin p x) \, dp.$$

where

$$c_1(p) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \cos p x \, dx$$

$$c_2(p) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \sin p x \, dx.$$

So, $u(x,t)$ will be 0 to infinity $e^{-k^2 c^2 t}$ and c_1 is nothing but, $c_1 p$ is nothing but it is integral minus infinity to plus infinity $1/\pi$ will come out minus infinity to plus infinity it is $f(x)$ and it is you can put it $f(\xi)$ or something $f(\xi)$ because x is also here and x is also here. So, it will be a confusion so you can take $f(\xi)$ here $f(\xi) \cos p \xi$ and it is $\cos p x \, d\xi$ this term come here plus $e^{-k^2 c^2 t}$ and with this minus infinity to plus infinity again it is $f(\xi) \cos$ or \sin it is $\sin p \xi$ and $\sin p x \, d\xi$ and whole multiplied by dp .

So, in this way we will get by this expression go on when we simplify this nothing but $1/\pi$ integral 0 to infinity $e^{-k^2 c^2 t}$. So, it is again one more integral minus infinity to plus infinity and it is $f(\xi)$ is common from both the terms and it is $\cos a \cos b$ plus $\sin a \sin b$ which is nothing but $\cos(a-b)$, $\cos(a-b)$ or $d\xi$ into dp . So, this will be the required solution of this differential equation when we have an infinite bar.

So, in this way we can solve we can solve such type of problems, we can solve such type of problems when the bar is tending to infinity from both the sides using Fourier integrals. Now come to a use of Fourier transforms.

(Refer Slide Time: 11:59)

Use of Fourier transforms

The temperature distribution $u(x, t)$ in a thin, homogeneous, infinite bar can be modelled by the initial boundary value problem:

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}, \quad -\infty < x < \infty, \quad t > 0, \quad (4)$$

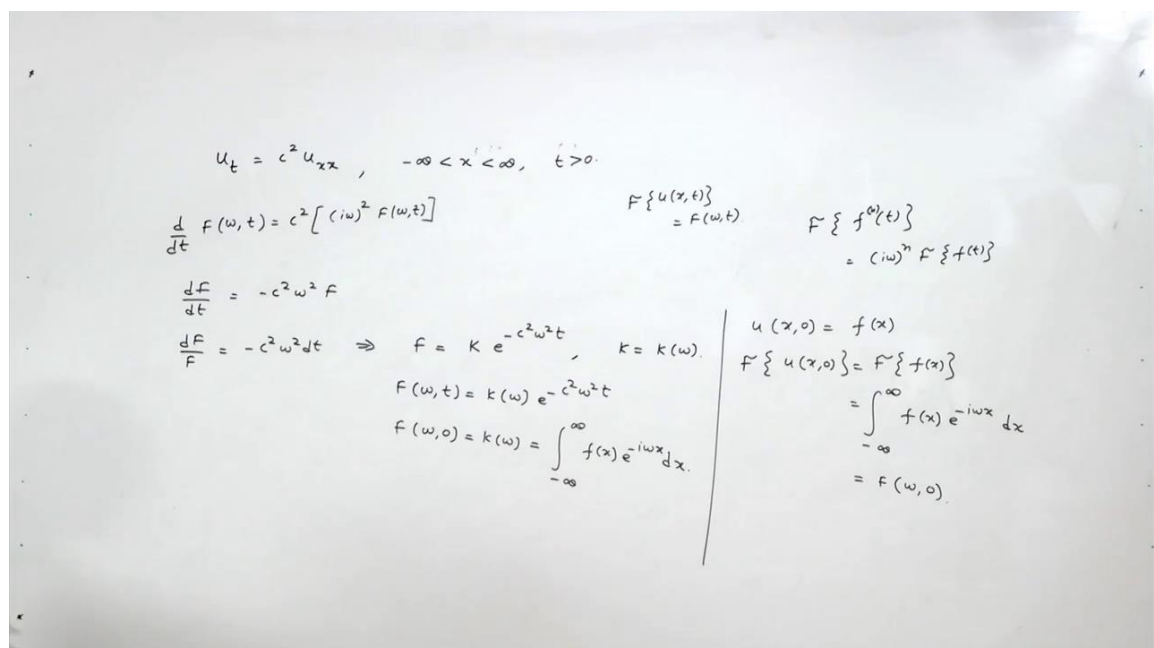

$$u(x, 0) = f(x),$$

$u(x, t)$ is finite as $|x| \rightarrow \infty$. Find $u(x, t)$, $t > 0$.

7

So, let us discuss this problems that temperature distribution $u(x, t)$ in a thin homogeneous infinite bar can be modelled by the initial boundary value problem this. So, now, how can we use Fourier transforms? So, we have already discussed the applications of Fourier series and Fourier integrals that how can we use Fourier series or Fourier integrals.

(Refer Slide Time: 12:33)

Handwritten derivation showing the application of Fourier transforms to the heat equation:

$$u_t = c^2 u_{xx}, \quad -\infty < x < \infty, \quad t > 0.$$

$$\frac{d}{dt} F(u, t) = c^2 [(i\omega)^2 F(\omega, t)]$$

$$\frac{dF}{dt} = -c^2 \omega^2 F$$

$$\frac{dF}{F} = -c^2 \omega^2 dt \Rightarrow F = K e^{-c^2 \omega^2 t}, \quad K = k(\omega).$$

$$F(\omega, t) = k(\omega) e^{-c^2 \omega^2 t}$$

$$f(\omega, 0) = k(\omega) = \int_{-\infty}^{\infty} f(x) e^{-i\omega x} dx.$$

$$u(x, 0) = f(x)$$

$$F\{u(x, 0)\} = F\{f(x)\}$$

$$= \int_{-\infty}^{\infty} f(x) e^{-i\omega x} dx$$

$$= F(\omega, 0).$$

Now, let us discuss Fourier transforms. Now in this problem it is u_t it is equal to $c^2 u_{xx}$, u_t equal to u_{xx} this and minus infinite less than x less than infinite and t greater than 0. So, it is again an infinite bar x is varying from minus infinity to plus infinity and $u(x, 0)$ is equal to $f(x)$ it is given to us, it is also given to us that $u(x, t)$ is finite as x tending to plus or minus infinity. So, what will be $u(x, t)$? $u(x, t)$ is a temperature distribution function so how can you find $u(x, t)$ again.

Now since x is varying from both the sides it is minus infinity to plus infinity. So, take Fourier transform both the sides. Now here x is varying from minus infinity to plus infinity take Fourier transform respect to x . So, first where we have to identify that with because it contain 2 variable, because u is nothing but function of 2 variable.

So, first we have to decide that respect to which variable Fourier transform is to be taken. So, now, it is x is varying from minus infinity to plus infinity. So, take Fourier transform respect to x . So, when you take Fourier transforms here, Fourier transform of u_t which is nothing, but Fourier transform of $\frac{\partial u}{\partial t}$, it is nothing, but minus into plus infinity $\frac{\partial u}{\partial t}$ of because we are taking Fourier transform with respect to x .

So, it will be e^{kx} power minus $\eta \omega x$ $d \omega$, $\eta \omega x$ $d x$. So, since it is free from t . So, we can take $\frac{\partial}{\partial t}$ outside. So, it will be $\frac{d}{dt}$ of minus infinity to plus infinity u into e^{kx} minus $\eta \omega x$ $d x$ which is nothing but $\frac{d}{dt}$ of Fourier transform of u , Fourier transform of $u(x, t)$. So, that is why if we take Fourier transform of this side because we are taking Fourier transform with respect to x . So, when we take Fourier transform this side this is nothing but $\frac{d}{dt}$ of suppose Fourier transform of $u(x, t)$ is $F(\omega, t)$. Suppose we are Fourier transform of $u(x, t)$ we are taking as $F(\omega, t)$. So, it is $F(\omega, t)$, Fourier transform of $u(x, t)$ is $F(\omega, t)$ which is equal to c^2 times. Now Fourier transform u_{xx} , now Fourier transform we already know that Fourier transform of n th derivative of t is nothing but, n th derivative of t is nothing but $\eta \omega e^{kx}$ power n and Fourier transform of $f(t)$.

So, we are taking Fourier transforms respect to x . So, here it will be it is double derivative, so it is $\eta \omega^2$ Fourier transform of $u(x, t)$ which I taking as $F(\omega, t)$. So, when we simplify this, so this is $\frac{df}{dt}$ where f is a function of ω and t is equal to minus $c^2 \omega^2$ into f . So, it is $\frac{df}{dt}$ upon F is equals to minus c

square omega square dt. So, when we integrate this it will be x is equals to some K times e k power minus c square omega square t.

So, when we integrate both the sides we get this expression. So, this F is a function of, this F is a function of omega and t. So, this K will be nothing but, here K will be nothing, but function of omega. So, in this way we obtain we obtain F omega t which is nothing, but K omega e k power minus c square omega square t. Now it is given to us that u 0 x, u x 0 is equals to f x. So, u x 0 is equal to f x, now take Fourier transform both the sides. So, Fourier transform of u x 0 will be Fourier transform of f x and will be equal to minus infinity to plus infinity f x e k power e k power minus eta omega x into dx and that will be nothing, but F omega 0 that you can simply take, because you are putting t equal to 0, because Fourier transforms of u x t is F omega t and when we put t equal to 0 both the sides, so F omega 0 will be nothing, but Fourier transform of u x 0. So, Fourier transform of u x 0 will be nothing but F omega 0.

So, when you take F omega 0 over here u get K omega. So, this K omega will be nothing, but integral minus infinity to plus infinity f x e k power minus eta omega x into dx. So, now, take inverse Fourier transforms both the sides in this expression. So, what we are having. So, what we obtained basically?

(Refer Slide Time: 19:10)

$$\begin{aligned}
 F(\omega, t) &= K(\omega) e^{-c^2 \omega^2 t} \\
 u(x, t) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} F(\omega, t) e^{i\omega x} d\omega \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} K(\omega) e^{-c^2 \omega^2 t} e^{i\omega x} d\omega \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(\xi) e^{-i\omega \xi} e^{-c^2 \omega^2 t} e^{i\omega x} d\xi d\omega \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(\xi) e^{-i\omega(\xi-x)} e^{-c^2 \omega^2 t} d\xi d\omega \\
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(\xi) \cos \omega(\xi-x) e^{-c^2 \omega^2 t} d\xi d\omega
 \end{aligned}$$

So, now if you take, now, $F(\omega, t)$ is nothing, but $K(\omega, e^{k^2 - c^2 \omega^2 t})$ where $K(\omega)$ is given by this expression. Now taking inverse Fourier transform both the side $u(x, t)$ will be given by, $u(x, t)$ will be given by $\frac{1}{2\pi} \int_{-\infty}^{+\infty} F(\omega, t) e^{i k x - (k^2 - c^2 \omega^2) t} d\omega$. So, that will be equal to $\frac{1}{2\pi} \int_{-\infty}^{+\infty} K(\omega) e^{i k x - (k^2 - c^2 \omega^2) t} d\omega$.

Now, $K(\omega)$ is given by this expression to substitute it over here, you substitute it over here. So, what we will obtain? It is nothing, but $\frac{1}{2\pi} \int_{-\infty}^{+\infty} f(\zeta) e^{i k x - (k^2 - c^2 \omega^2) t} d\zeta$ into $e^{i k x - (k^2 - c^2 \omega^2) t}$ into $e^{i k x - (k^2 - c^2 \omega^2) t} d\zeta$.

So, when we simplify this. So, now, we further simplify this. So, $\frac{1}{2\pi} \int_{-\infty}^{+\infty} f(\zeta) e^{i k x - (k^2 - c^2 \omega^2) t} d\zeta$ minus infinity to plus infinity, minus infinity to plus infinity it is $f(\zeta)$ and $e^{i k x - (k^2 - c^2 \omega^2) t}$ it is $\int_{-\infty}^{+\infty} f(\zeta) e^{i k x - (k^2 - c^2 \omega^2) t} d\zeta$. Now $e^{i k x - (k^2 - c^2 \omega^2) t}$ is $e^{i k x} e^{-k^2 t} e^{c^2 \omega^2 t}$ is $\cos(\theta) - i \sin(\theta)$ and it will be nothing but \cos this expression is nothing but $\cos(\omega \psi - x - \omega t)$.

Now, this is even function ω^2 even here, so this is even. Now \sin is odd in ω it is even, even into odd is odd. So, this will be 0 from minus infinity to plus infinity so we will left with only one term which is $\frac{1}{2\pi} \int_{-\infty}^{+\infty} f(\zeta) \cos(\omega \psi - x - \omega t) d\zeta$. So, this will be the final solution of, this will be the final solution of this. So, hence we will obtain the solution of the given differential equation, is it Ok.

(Refer Slide Time: 22:43)

Continued...

Solution. Since domain of the bar is $-\infty < x < \infty$, we use Fourier transform w.r.t x . Let $\mathcal{F}[u(x, t)] = F(\omega, t)$. Taking Fourier transform on both sides of (4), we get

$$\mathcal{F}\left[\frac{\partial u}{\partial t}\right] = c^2 \mathcal{F}\left[\frac{\partial^2 u}{\partial x^2}\right], \text{ (by linearity)}$$

Now, $\mathcal{F}\left[\frac{\partial u}{\partial t}\right] = \int_{-\infty}^{\infty} \frac{\partial u}{\partial t} e^{-i\omega x} dx = \frac{\partial}{\partial t} \int_{-\infty}^{\infty} u e^{-i\omega x} dx$

$$= \frac{\partial}{\partial t} F(\omega, t)$$

Also, $\mathcal{F}\left[\frac{\partial^2 u}{\partial x^2}\right] = -\omega^2 F(\omega, t)$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

So, here we have solved the same problem, the technique which I have solved. So, when we simplify we obtained the same solution which we obtained over here. So, that is all for this problems now see one more problem using Fourier transforms, this is Laplace equation $\Delta^2 u$ upon Δx square plus Δx u upon Δy square equal to 0 and x is tending from minus infinity to plus infinity u is finite u is varying from 0 to π .

(Refer Slide Time: 23:04)

Problem

Using Fourier integral transform, solve

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0, \quad -\infty < x < \infty, \quad 0 < y < \pi,$$

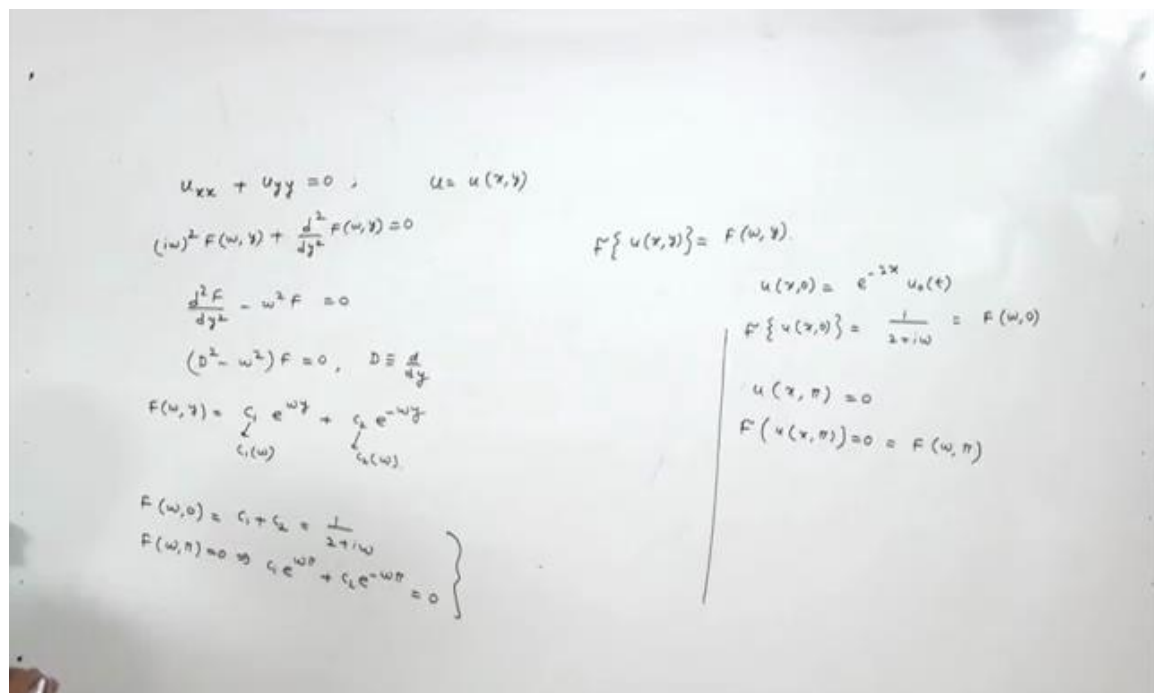

$$u(x, 0) = e^{-2x} u_0(t),$$

$$u(x, \pi) = 0, \quad -\infty < x < \infty.$$

11

So, we will apply Fourier transforms respect to x. So, let us see how. So, what is a equation given to us.

(Refer Slide Time: 23:21)

$u_{xx} + u_{yy} = 0, \quad u = u(x, y)$
 $(i\omega)^2 F(\omega, y) + \frac{d^2}{dy^2} F(\omega, y) = 0$
 $\frac{d^2 F}{dy^2} - \omega^2 F = 0$
 $(D^2 - \omega^2) F = 0, \quad D \equiv \frac{d}{dy}$
 $F(\omega, y) = c_1 e^{\omega y} + c_2 e^{-\omega y}$
 $\left. \begin{aligned} F(\omega, 0) &= c_1 + c_2 = \frac{1}{2 + i\omega} \\ F(\omega, \pi) &= 0 \Rightarrow c_1 e^{\omega\pi} + c_2 e^{-\omega\pi} = 0 \end{aligned} \right\}$

$F\{u(x, y)\} = F(\omega, y)$
 $u(x, 0) = e^{-2x} u_0(t)$
 $F\{u(x, 0)\} = \frac{1}{2 + i\omega} = F(\omega, 0)$
 $u(x, \pi) = 0$
 $F\{u(x, \pi)\} = 0 = F(\omega, \pi)$

Now, see it is $u_{xx} + u_{yy} = 0$, basically u is a function of x and y here. Now x is varying from minus infinity to plus infinity as given and y is varying from 0 to π , we have to apply Fourier transforms respect to x . So, apply Fourier transform both the sides. So, here you apply Fourier transform it is $\eta \omega^2$ Fourier transform of $u(x, y)$ which I am taking as ωy . So, Fourier transform of $u(x, y)$ because I am applying Fourier transform respect to x .

So, it will be nothing, but I am assuming as $F(\omega, y)$ plus, now why we are not taking respect to y . So, it remains as it is D^2 upon $d^2 y$ of Fourier transform of ωy is equals to 0 Fourier transform of $u(x, y)$, so that will be 0 . So, it will be nothing, but $D^2 f$ upon $d^2 y$ square minus $\omega^2 f = 0$. So, this is D^2 square minus ω^2 $F = 0$ where D is nothing but d upon $d y$ when you simply, so $F(\omega, y)$ comes out to be $c_1 e^{k \omega y} + c_2 e^{-k \omega y}$. Again c_1 and c_2 are arbitrary constant and it is a function of 2 variable ω and y . So, we can take c_1 as a function of ω and c_2 as a function of ω .

Now, we will apply the conditions given to us. Now $u(x, 0)$ is, $u(x, 0)$ is given to us as e^{-kx} power minus 2 $u(x, 0)$ take Fourier transform of both the sides. So, Fourier transform of $u(x, 0)$ will be nothing but 1 upon 2 plus $\eta \omega$ and that is nothing but when you substitute $y = 0$ here. So, that will be nothing but $F(\omega, 0)$. So, when you take $F(\omega, 0)$ here. So, when you take $F(\omega, 0)$ here, so $F(\omega, 0)$ is nothing, but $c_1 + c_2$ which will be equals 1 upon 2 plus $\eta \omega$.

Now, second condition is $u(x, \pi) = 0$. Now $u(x, \pi) = 0$, so when you take Fourier transform both the sides $u(x, \pi)$ it will be 0 which is equals to $F(\omega, \pi)$ because when you substitute $y = \pi$ both the side we get back to this expression. So, from here when you take $F(\omega, \pi)$ which is equal to 0 . So, this implies $c_1 e^{k \omega \pi} + c_2 e^{-k \omega \pi}$ will be equal to 0 .

Now, solving these 2 equations we can get the values of c_1 and c_2 . So, c_1 and c_2 we can obtain from here we can easily solve these 2 equations and find the values of c_1 and c_2 which we can substitute over here. So, what are c_1 and c_2 that we can obtain, I am not solving for c_1 and c_2 .

(Refer Slide Time: 27:28)

Now for x , $F(\omega, y)$ is nothing but $c_1(\omega) e^{i\omega y} + c_2(\omega) e^{-i\omega y}$. So, here c_1 and c_2 are governed by these 2 equations we can simply solve these 2 equations to find the values of c_1 and c_2 .

So, the inverse, take the inverse Fourier transforms both the sides. So, it will be $u(x, y)$ will be equal to $\frac{1}{2\pi} \int_{-\infty}^{\infty} F(\omega, y) e^{i\omega x} d\omega$. So, it will be $\frac{1}{2\pi} \int_{-\infty}^{\infty} (c_1(\omega) e^{i\omega y} + c_2(\omega) e^{-i\omega y}) e^{i\omega x} d\omega$. So, whatever c_1 c_2 we obtain from these 2 equations we simply substitute it over here and we get the final solution we get the final answer $u(x, y)$ of this Laplace equation.

So, in this way whenever we have an x or y ranging from minus infinity to plus infinity we can solve those equations using Fourier transforms. So, that is all for this lecture.

Thank you.
