Lecture – 07
Methods for finding particular integral for second-order linear differential equations with constant coefficients II

Hello friends. Welcome to my second lecture on Methods for Finding Particular Integral for Second-order Linear Differential Equations with Constant Coefficients.

(Refer Slide Time: 00:36)

In my last lecture, we were trying to find the particular integral in the case of the differential equation $D^2 y + y = \cos^2 \frac{1}{2} x$ and we could not find it because we had to write $\cos^2 \frac{1}{2} x$ in the form of $\frac{1 + \cos x}{2}$ and when we write it in this form, what happens is that we have to find the particular integral for $\frac{1}{D^2 + 1}$ $\cos x$, but $\frac{1}{D^2 + 1} \cos x$ cannot be found from the formula $\frac{1}{D^2 + a^2} \cos ax = \frac{1}{\phi(D^2)} \cos ax = \frac{1}{\phi(a^2)} \cos ax$, we cannot find the particular integral in this case because when we replace D^2 by $-a^2$ that is D^2 by -1 $r^2 - 1$ this $D^2 + 1$ on replacing D^2 by -1 becomes 0.

So, phi minus a square should not be 0 to apply this formula and therefore, let us now discuss how to find the particular integral in the case of 1 over D square plus c square cos c x.

(Refer Slide Time: 02:50)

$\frac{1}{f(D)} \cos cx$ or $\frac{1}{f(D)} \sin cx$ (exceptional case):
 Suppose $f(D) = \phi(D^2) = D^2 + c^2$,
 then $\phi(-c^2) = 0$,
 hence we can not apply
 $\frac{1}{\phi(D^2)} \cos cx = \frac{1}{\phi(-c^2)} \cos cx$

2

So, let us discuss how to find the particular integral in the case of 1 over f D cos c x or 1 over f D sin c x which are where in the exceptional case we have f D equal to D square plus c square and we see that phi D square when c square D square is replaced by minus c square becomes 0. So, we have not able to apply the formula 1 over phi D square cos c x equal to 1 over phi minus c square cos c x, we will prove that 1 over phi D square cos c x which is 1 over D square plus c square cos c x gives us x sin c x over 2 c.

(Refer Slide Time: 03:09)

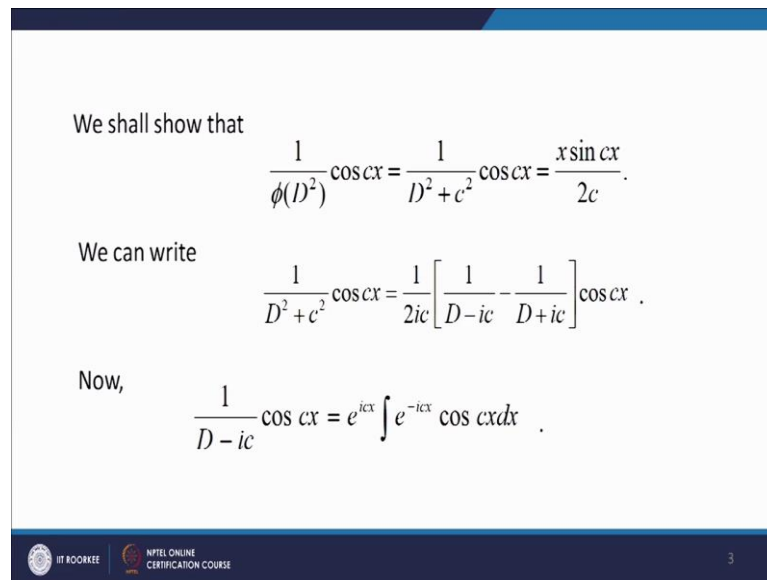

We shall show that

$$\frac{1}{D(D^2+c^2)} \cos cx = \frac{1}{D^2+c^2} \cos cx = \frac{x \sin cx}{2c}.$$

We can write

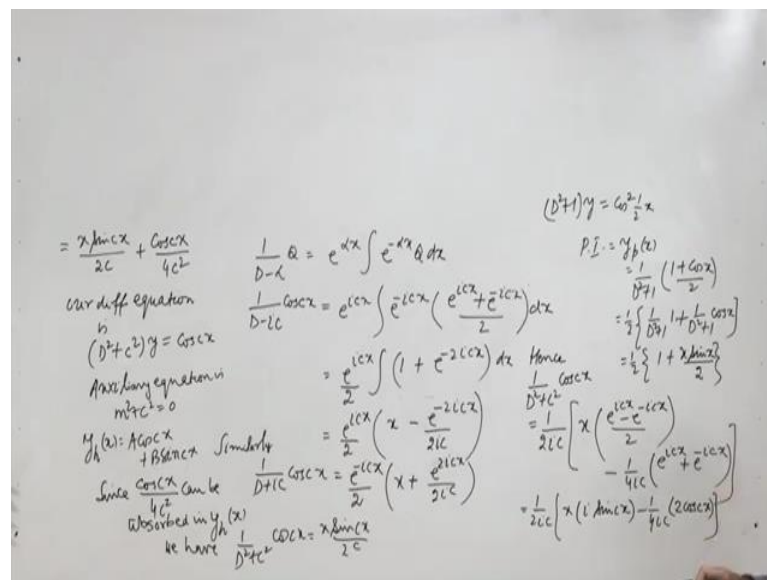

$$\frac{1}{D^2+c^2} \cos cx = \frac{1}{2ic} \left[\frac{1}{D-ic} - \frac{1}{D+ic} \right] \cos cx.$$

Now,

$$\frac{1}{D-ic} \cos cx = e^{icx} \int e^{-icx} \cos cx dx.$$

So, let us see how we do this, we can write 1 over D square plus c square as 1 over 2 i c, 1 over D minus i c minus 1 over D plus i c operating on cos c x that is we break 1 over D square plus c square in partial fractions.

(Refer Slide Time: 03:39)

Handwritten notes on a whiteboard showing the derivation of the particular integral for the differential equation $(D^2+c^2)y = \cos cx$. The notes include the partial fraction decomposition of $\frac{1}{D^2+c^2}$ into $\frac{1}{2ic} \left(\frac{1}{D-ic} - \frac{1}{D+ic} \right)$, the use of the inverse operator formula $\frac{1}{D-a} f(x) = e^{ax} \int e^{-ax} f(x) dx$, and the final result $y_p = \frac{x \sin cx}{2c}$.

Now let us recall that we had proved that 1 over D minus alpha when operates on q or you can say r x then we had e to the power minus alpha x integral e to the power e to the power alpha x e to the power minus alpha x into q d x.

So, let us apply this formula here and to by using this formula $\frac{1}{D - ic} \cos cx$ will be e to the power icx integral e to the power $-icx$ $\cos cx dx$ now then what we will have is e to the power $-icx$ $\cos cx$ we can write as e to the power icx plus e to the power $-icx$ divided by 2 by the Euler's formula we know that for $i\theta$ is $\cos \theta + i \sin \theta$ and e to the power $-i\theta$ is $\cos \theta - i \sin \theta$, so from there $\cos \theta$ is e to the power $i\theta + e$ to the power $-i\theta$ by 2. Now, this is equal to e to the power icx integral, this will be $\frac{1}{2} \int \frac{e^{icx} + e^{-icx}}{2} dx$ let us integrate it and we get then integral of 1 is x and then e to the power $-2icx$ divided by $2ic$.

Similarly, we can write the value of $\frac{1}{D + ic} \cos cx$. This is equal to we get this; now let us subtract from the value of $\frac{1}{D - ic} \cos cx$ the value of $\frac{1}{D + ic} \cos cx$ and then divide by $2ic$ hence $\frac{1}{D^2 + c^2} \cos cx$ is equal to $\frac{1}{2ic}$ from $\frac{1}{D - ic} \cos cx$. We subtract the value of $\frac{1}{D + ic} \cos cx$ and so this will give you x times $\cos e$ to the power icx minus e to the power $-icx$ divided by 2 and when we then we will have \sin here 2 becomes $4ic$ and we get e to the power $-icx$ here we get e to the power icx . So, e to the power icx plus e to the power $-icx$ and this is equal to $\frac{1}{2ic}$ times. Now e to the power $i\theta$ minus e to the power $-i\theta$ by 2 is $i \sin \theta$.

So, we get i times $\sin cx$ and then here we have $\frac{1}{4ic} e$ to the power $i\theta$ plus e to the power $-i\theta$ is $2 \cos \theta$. So, $2 \cos cx$ and thus we have $x \sin cx$ by $2c$ and we have i this 2 will cancel with that 2 here. So, here $\cos cx$ divided by $4c^2$, now our differential equation is of the type our differential equation is $D^2 + c^2 y = \cos cx$.

So, auxiliary equation will be $m^2 + c^2 = 0$. So, complementary function $y_h x$ will be equal to $a \cos cx + b \sin cx$ and then when we will operate now we will operate $\frac{1}{D^2 + c^2}$ on $\cos cx$ to find the particular integral we get $\frac{x \sin cx}{2c} + \frac{\cos cx}{4c^2}$. So, this term $\frac{\cos cx}{4c^2}$ can be observed in the term $a \cos cx$ occurring in the complementary function and therefore, when we write the result for $\frac{1}{D^2 + c^2} \cos cx$ we just retain $\frac{x \sin cx}{2c}$.

So, we say that since of $\cos c x$ over $4 c$ square can be observed in $y h x$ we have 1 over D square plus c square $\cos c x$ equal to $x \sin c x$ by $2 c$ and similarly we can prove similarly we can show 1 over D square plus c square $\sin c x$ equal to minus x by $2 a \cos c x$.

(Refer Slide Time: 10:19)

Example 1.
 $(D^2 + 1) y = \cos^2(x/2).$

Example 2.
 $(D^2 + 1) y = \sin^2(x/2) + e^x.$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

Now, with these formulas we can then find the particular integral easily in the case where ϕ minus a square becomes 0 for example, one of let us look at the equation D square plus 1 y equal to \cos square 1 by $2 x$. So, particular integral $y p x$ is equal to 1 over D square plus 1 operating on \cos square x 1 by 2 which we can write as 1 plus $\cos x$ by 2 which is equal to 1 by 2 1 over D square plus 1 operating on 1 and then we have 1 over D square plus 1 operating on $\cos x$ 1 can be regarded as e to the power $0 x$. So, this is 1 over 2 d over D is replaced by a 0 . So, we have 1 and then 1 over D square plus c square $\cos c x$ gives $x \sin c x$ over $2 c$. So, c is equal to 1 here. So, we have $x \sin x$ divided by 2 by using the formula which we have just proved and similarly we can solve example 2.

In the case of example 2, when we find the particular integrals \sin square x by 2 is written as 1 minus $\cos x$. So, over 2 and then we apply the formula same formula 1 over D square plus c square $\cos c x$ equal to $x \sin x$ by $2 c$ to obtain the particular integral.

(Refer Slide Time: 11:51)

Show that $\frac{1}{f(D)} e^{ax} V = e^{ax} \frac{1}{f(D+a)} V$, V being any function of x .

Proof. Hence, $D(e^{ax} V) = e^{ax} DV + a e^{ax} V$
 $= e^{ax} (D+a) V$,
 $D^2(e^{ax} V) = e^{ax} (D+a)^2 V$.

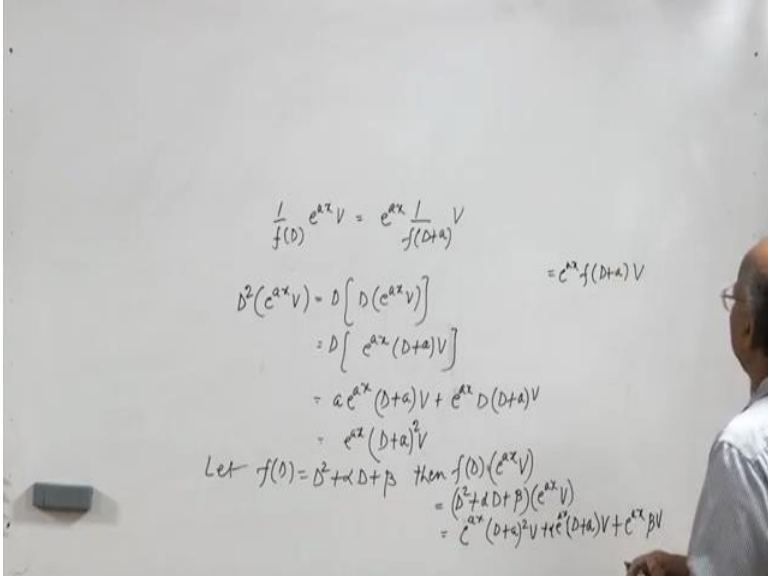

$f(D) (e^{ax} V) = e^{ax} f(D+a) V$.

This suggests that

$$\frac{1}{f(D)} (e^{ax} V) = e^{ax} \frac{1}{f(D+a)} V.$$

7

(Refer Slide Time: 11:59)

$$\frac{1}{f(D)} e^{ax} V = e^{ax} \frac{1}{f(D+a)} V$$

$$D^2(e^{ax} V) = D[D(e^{ax} V)] = D[e^{ax}(D+a)V] = a e^{ax}(D+a)V + e^{ax} D(D+a)V = e^{ax}(D+a)^2 V$$

Let $f(D) = D^2 + \alpha D + \beta$ then $f(D)(e^{ax} V) = (D^2 + \alpha D + \beta)(e^{ax} V) = e^{ax}(D+a)^2 V + \alpha e^{ax}(D+a)V + \beta e^{ax} V$

Now, let us look at another formula which is given by $\frac{1}{f(D)} e^{ax}$ into V where V real function of x and a is some constant. So, this when $\frac{1}{f(D)}$ operates on e^{ax} into V what we get is e^{ax} into one upon $f(D+a)$ plus a operating on V . So, this formula is very useful in the case, earlier we have considered $\frac{1}{f(D)}$ operating on e^{ax} this formula gives us $\frac{1}{f(D+a)} e^{ax}$ provided $f(D+a) \neq 0$, but if $f(D+a) = 0$ then we cannot apply this formula. So, the case where this $f(D+a)$ becomes 0 can be handled by the formula which we are now going to prove.

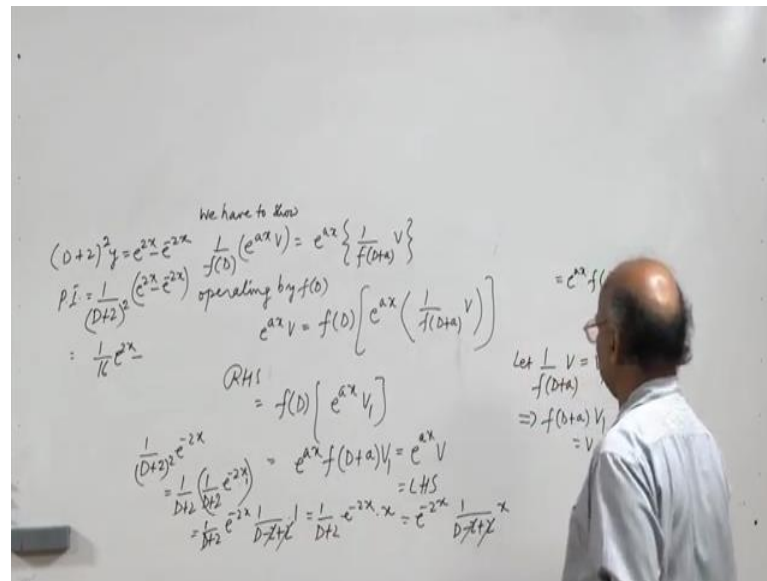

So, let us see how we prove this result when you find the derivative of the function e to the power $a x$ into V you get e to the power $a x$ into derivative of V plus a times e to the power $a x$ derivative into V and this can be expressed as e to the power $a x$ d plus a operating on V and then you again differentiate that is you find the second derivative of e to the power $a x$ into V what you get is if you find $D^2 e$ to the power $a x$ into V then this is d of and derivate of e to the power $a x$ into V we have found as e to the power $a x$ D^2 plus a operating on V let us operate by D . So, derivate of e to the power $a x$ is a times e to the power $a x$.

Then D plus a operating on V then e to the power $a x$ D operating on d plus $a V$. Now this can be expressed as e to the power $a x$ then we have $a d V$ a square d . So, we can write it as d plus a whole square $V D$, D is D square V and then $a D V$ and then $a D V$ becomes $2 a d V$ and then we have a square v . So, a to the power $a x$ D plus a whole square we get and thus we if we apply $f D$ operator if we apply suppose $f D$ is equal to D^2 plus αd plus β .

Let $f D V$ equal to D^2 plus αd plus β then $f D$ operating on e to the power $a x$ into b will give you D^2 plus αd plus β operating on this and. So, what you will get actually D^2 plus αd plus β operating on e to the power $a x$ into V . So, this will give you e to the power $a x$ e to the power $a x$ D plus a whole square operating on V then α times d plus a e to the power $a x$ e to the power $a x$ D plus $a V$ and then e to the power $a x$ βb which is equal to e to the power $a x$ $f D$ plus a operating on v . So, this is what we get.

And so thus ultimately we get $f D$ operating on e to the power $a x$ into V , it is equal to e to the power $a x$ $f D$ plus a into V . So, this suggests us this formula 1 over $f D$ operating on e to the power $a x$ into V equal to e to the power $a x$ 1 over $f D$ plus a into V . Now let us see how we get this.

(Refer Slide Time: 16:49)

So, we have to prove $\frac{1}{f(D)} e^{ax} V$ equal to $e^{ax} \frac{1}{f(D+a)} V$. So, we do is let us operate by $f(D)$ on both sides. So, operating in by $f(D)$; $f(D)$ in $\frac{1}{f(D)}$ are inverse operators. So, we get $e^{ax} V$ equal to $f(D)$ operating on $e^{ax} \frac{1}{f(D+a)} V$ now let us look at the right hand side.

(Refer Slide Time: 18:01)

To prove this result, let us operate by $f(D)$ on both sides of this equation, then,

$$e^{ax} V = f(D) \left\{ e^{ax} \frac{1}{f(D+a)} V \right\}.$$

The right side can be written as

$$\begin{aligned} f(D) (e^{ax} V_1) \text{ where } \{f(D+a)\}^{-1} V &= V_1 \\ &= e^{ax} f(D+a) V_1 \\ &= e^{ax} V \end{aligned}$$

which is left hand side, using this formula, we can find $\frac{1}{f(D)} e^{ax}$ when $f(\alpha) = 0$.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So, let us assume that $\frac{1}{f(D+a)}$ operating on V is equal to V_1 , let us assume that $\frac{1}{f(D)}$ operating on V is equal to V one. So, we shall get $f(D)$ right hand side;

right hand side here will be equal to $f D$ operating on e to the power $a x$ into V^{-1} and when $f D$ operates on e to the power $a x$ into V what we had got earlier that if this is e to the power $a x$ $f D$ plus $a V^{-1}$ we have proved this earlier.

Now, this implies that $f D$ plus a when you operate on both sides you get $f D$ plus $a V^{-1}$ equal to v . So, this will be equal to e to the power $a x$ into V and this is what we had to prove this is the left hand side. So, left right hand side left hand side are same and therefore the formula $\frac{1}{f D} e$ to the power $a x$ into V equal to e to the power $a x$ $\frac{1}{f D + a}$ operating on V is true.

(Refer Slide Time: 19:24)

Example.

$$(D^2 + 4D + 4) y = e^{2x} - e^{-2x}.$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Now, let us apply this formula to solve this equation $D^2 + 4D + 4$ which we can write as $(D + 2)^2$ $y = e^{2x} - e^{-2x}$ i will just find particular integral here complementary function is easy to find. So, this is $\frac{1}{(D + 2)^2} e^{2x} - e^{-2x}$ now this is equal to when $\frac{1}{(D + 2)^2}$ operates on e^{2x} we get $\frac{1}{2^2 + 4 \cdot 2 + 4}$. So, we get $\frac{1}{16}$ into e^{2x} minus.

Now when $\frac{1}{(D + 2)^2}$ operates on e^{-2x} on replacing D by -2 $(-2 + 2)^2$ become 0. So, we will apply this formula. So, we will let us see how we get this $\frac{1}{(D + 2)^2}$ operates separately on e^{-2x} let us operate on e^{-2x} . So, this is $\frac{1}{(D + 2)^2} e^{-2x}$. So, $\frac{1}{(D + 2)^2}$ operating on e^{-2x} , we can assume here 1. So, $\frac{1}{(D + 2)^2}$

plus 2 operating on e to the power minus 2 x into 1. So, V , we are taking as 1. So, this is equal to $\frac{1}{D+2} e^{-2x}$. D will be replaced by $D-2$ and this cancels we get $\frac{1}{D+2} e^{-2x} \cdot \frac{1}{D}$ is D means derivative $\frac{1}{D}$ means inverse of the derivative that is integral of 1 is x .

Now, again we will apply the formula which we have just proved e^{-2x} let us take V equal to $2x$. So, then we will have $e^{-2x} \cdot x$ will be replaced by $\frac{1}{D-2}$. Now $\frac{1}{D}$ is again integral of we have to make integral of x . So, that is $\frac{x^2}{2}$ and thus the particular integral is $\frac{x^2}{2} e^{-2x}$ and thus the particular integral is. So, this is how we can make use of this formula in the case where under placing d by a in the expression one by $f(D) e^{ax}$ becomes 0 now let us find another result.

(Refer Slide Time: 22:03)

Short method of finding $\frac{1}{f(D)} x^m$, where m is a positive integer:

In order to evaluate $\frac{1}{f(D)} x^m$, we expand $\frac{1}{f(D)}$ in ascending powers of D and operate on x^m with the result. It is clear that the terms of the expansion beyond the m^{th} power of D will all be zero, since

$$D^{m+1} x^m = 0.$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

So, now we discuss how to find the particular integral in case $r x$ is of the form x to the power m where m is a positive integer.

(Refer Slide Time: 22:14)

$(D+2)^2 y = e^{2x} - e^{-2x}$
 $P.I. = \frac{1}{(D+2)^2} (e^{2x} - e^{-2x})$
 $= \frac{1}{16} e^{2x} - \frac{1}{2} e^{-2x}$

$P.I. = \frac{1}{f(D)} x^m$
 $(D^2 - D - 6)y = 1 + x^2$
 $P.I. = \frac{1}{D^2 - D - 6} (1 + x^2)$
 $= \frac{1}{D^2 - D - 6} e^{0x} + \frac{1}{D^2 - D - 6} x^2$
 $= \frac{1}{6} - \frac{1}{6} \left(1 + \frac{D - D^2}{6}\right) x^2$
 $= -\frac{1}{6} - \frac{1}{6} \left\{ 1 - \left(\frac{D - D^2}{6}\right) + \left(\frac{D - D^2}{6}\right)^2 \right\} x^2$

So, when we have to find, but particular integral of this type where m is positive integer what we do is in order to evaluate 1 over f D x to the power m we extend f D in ascending powers of D and then operate on x to the power m. Since the derivative m plus 1 of the derivative of x to the power m is 0, all derivatives more than 1 plus are also 0 while writing the expression in the ascending powers of d we need to write the derivate of the powers of V only up to m rest of the terms will be 0. So, we can evaluate particular integral by writing in the ascending powers of D.

(Refer Slide Time: 23:10)

Example.

$$(D^2 - D - 6)y = 1 + x^2.$$

Let us see; we now apply this formula suppose we have the equation $D^2 - 6y = 1 + x^2$.

So, this is let us say; let us find particular integral here. So, $\frac{1}{D^2 - 6}$ operating on $1 + x^2$ can be taken again by writing e to the power $0x$. So, $\frac{1}{D^2 - 6}$; $D^2 - 6$ e^{0x} and then $\frac{1}{D^2 - 6}$ x^2 . So, this is given by replacing d by 0 we get $\frac{1}{6}$ and this is and $\frac{1}{D^2 - 6}$ when operates on x to the power 2 , we have to expand it in ascending powers of D . So, that we can do like this $\frac{1}{6} \left(1 + \frac{D^2}{6} + \dots \right)$ x^2 divided by 6 raise to the power minus 1 .

Now, we will expand it like the expand $1 + x$ to the power minus 1 . So, this 1 will be $1 + x$ to the power minus 1 is $1 - x + x^2 - x^3$. Now x^3 I am not writing because x^3 in the x^3 when you do, $D - D^2$ to the; by 6 to the power cube will minimum power of D will be three, but we have x^2 here third derivative x^2 is 0 . So, we need not write those terms we can stop here and then.

So, this operates on this operates on x^2 and so what we will get is $\frac{1}{6} \left(1 - \frac{D^2}{6} + \dots \right)$ x^2 or in square gives $2x$ D^2 on x^2 gives 2 . So, $2x$ minus 2 divided by 6 and then we have $D - D^2$ 1 . We find; we get D^2 then we get D^3 then we get D to the power 4 . So, D^2 1 operates on x^2 gives you 2 . So, 2 by 36 , all other terms will contribute 0 because when they operate on x^2 we what we get is 0 . So, this is the particular integral in this case. So, when $\frac{1}{f(D)}$ operates on x to the power m where m is an integer we have to extend $\frac{1}{f(D)}$ in ascending powers of D .

(Refer Slide Time: 26:18)

Now, I will tell you how this expression is justified suppose we have 1 over 1 plus D operates on x to the power m and we are writing it as 1 minus D plus D square minus D cube and so on, we are expanding 1 over 1 plus D as 1 minus D plus D square minus D cube and so on like we expand 1 plus x to the power m minus 1. So, how this expansion is valid? Now what you do is to prove this, you operate by 1 plus D on both sides, so operating by 1 plus D.

We will have this, now 1 plus D and 1 over 1 plus D are inverse of operators. So, we will have x to the power m and in the right side, let us operate 1 plus D on 1 minus D plus D square minus D cube, what you get is when you operate by 1 you get 1 minus D plus D square minus D cube and so on and when you operate by D, you get plus D minus D square plus D cube minus and so on x to the power m. So, these terms they go on cancelling and what we get is x to the power m. So, both sides are equal, and therefore 1 over 1 plus D, if we write as 1 minus D plus D square minus D cube like we expand binomial expansion, this just extension is valid justified.

So, then we have to find 1 over f D operating on x to the power m we have to expand 1 over f D in ascending powers of D.

Thank you.
