**Methods for finding Particular Integral for second-order**  
**linear differential equations with constant coefficients III**

Hello friends. Welcome to my third lecture on this topic Method for Finding Particular Integral for Second-order Linear Differential Equation with Constant Coefficients.

(Refer Slide Time: 00:32)

Evaluation of  $\frac{1}{f(D)}xV$ ,  $V$  being any function of  $x$ .

We have

$$D(xV) = xDV + V$$
$$D^2(xV) = xD^2V + 2DV.$$

Therefore,

$$\begin{aligned} f(D)xV &= (D^2 + aD + b)(xV) \\ &= D^2(xV) + aD(xV) + bxV \\ &= xD^2V + 2DV + a(xDV + V) + bxV \end{aligned}$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 2

We are trying to find the particular integral for second-order non-homogeneous linear differential equations where  $r x$  is of some special forms. So, if  $r x$  is of the form  $x$  into  $b$  where  $V$  is any function of  $x$  how we shall evaluate the particular integral.

(Refer Slide Time: 01:00)

$$\begin{aligned}
 \text{P.I.} &= \frac{1}{f(D)} xV \\
 \frac{1}{f(D)} xV &= x \frac{1}{f(D)} V + \left( \frac{d}{dD} \frac{1}{f(D)} \right) V \\
 (D^2 - 2D + 1)y &= x \sin x \\
 \text{P.I.} &= \frac{1}{D^2 - 2D + 1} x \sin x \\
 &= x \frac{1}{D^2 - 2D + 1} \sin x + \left( \frac{d}{dD} \frac{1}{D^2 - 2D + 1} \right) \sin x \\
 &= x \frac{1}{-2D} - \frac{(2D-2)}{(D^2 - 2D + 1)^2} \sin x \\
 &= -\frac{1}{2} x (-\cos x) - \frac{(2D-2)}{4(-1)} \sin x \\
 &= \frac{1}{2} x \cos x + \frac{1}{2} (\cos x - \sin x)
 \end{aligned}$$

So, particular integral in the case when  $rx$  is  $x$  into  $b$ . So, when you differentiate  $x$  into  $b$ , what we get is  $x$  into  $dv$  plus  $b$  because  $b$  is any function of  $x$  then  $D$  square when you operate on  $x$  into  $V$ , you get  $x D$  square  $b$  plus  $2 D b$ .

So, since  $D$  square is since  $f D$  is  $D$  square plus  $\alpha D$  plus  $\beta f D$  here I have taken  $D$  square plus  $a D$  plus  $b$ . So,  $f D x b f D$  operating  $x$  into  $b$  will give you  $D$  square plus  $a D$  plus  $b$  operating on  $x b$ . And since,  $D$  is a linear operator, so  $D$  square operating on  $x b$  plus  $a$  times  $D$  operating on  $x b$  plus  $b x V$ ; now  $D$  square  $x b$  the value of  $D$  square  $x$  we can put from here. So,  $x D$  square  $V$  plus  $2 D V$  and then derivative of  $x$  into  $b$  can be put it from here; so we have  $a$  times  $x D V$  plus  $V$  plus  $b x V$ .

(Refer Slide Time: 01:53)

The slide contains the following mathematical derivations:

$$f(D)xV = x(D^2V + aDV + bV) + (2D + a)V$$
$$= x f(D)V + f'(D)V. \quad \dots(1)$$

Let  $f(D)V = V_1$  then  $V = \{f(D)\}^{-1}V_1$ .

From equation (1)

$$f(D)\left(x\frac{1}{f(D)}V_1\right) = xV_1 + f'(D)\frac{1}{f(D)}V_1.$$

At the bottom of the slide, there are logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and a page number 3.

And which can then be written as  $x D^2 V$  plus  $a D V$  plus  $b V$  plus  $2 D a$  do  $2 D$  plus  $a$  operating on  $b$ . Now  $D^2 V$  plus  $a D V$  plus  $b V$  is nothing the operator  $f D$  operating on  $V$ . So, we have  $x$  into the  $f D$  operating on  $D$  and then  $2 D$  plus  $a$  can be interpreted as the derivative of  $f D$ . In short  $2 D$  plus  $a$  can be interpreted as  $f$  we have differentiated  $f D$  with respect to  $D$ .

Now let us suppose that when  $f D$  operates on the function  $V$ , we get another function say  $V_1$ . So, that when you apply the inverse operator  $1$  over  $f D$  on this equation  $f D V$  equal to  $V_1$ , we get  $V$  equal to  $1$  over  $f D$  operating on  $V_1$ . Now let us put the value of  $b$  as  $1$  over  $f D$  operating on  $V_1$  in this equation. So, we get  $f D$  operating on  $x$  into  $1$  over  $f D V_1$  equal to equal to  $x V_1$  because  $f D V$  is  $V_1$ . So,  $x$  into  $V_1$  and then  $f$  dash  $V$ ,  $f$  dash  $D$  operating on  $V$  is equal to  $1$  over  $f D V_1$ . Now we will operate on both sides by  $1$  over  $f D$ . So, we operate on this equation by  $1$  over  $f D$  since  $f D$  and  $1$  over  $f D$  are inverse to each other. So, we shall get on the left hand side only  $x$   $1$  over  $f D V_1$ .

(Refer Slide Time: 03:29)

Now operating by  $\frac{1}{f(D)}$ , we get

$$x \frac{1}{f(D)} V_1 = \frac{1}{f(D)} (xV_1) + \frac{f'(D)}{(f(D))^2} V_1$$

or

$$\frac{1}{f(D)} xV_1 = x \frac{1}{f(D)} V_1 - \frac{f'(D)}{(f(D))^2} V_1$$

Hence,

$$\frac{1}{f(D)} xV_1 = x \frac{1}{f(D)} V_1 + \left( \frac{d}{dD} \frac{1}{f(D)} \right) V_1 .$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 4

So, we get  $x \frac{1}{f(D)} V_1$  and then the right hand side we get as  $\frac{1}{f(D)}$  operating on  $xV_1$  then  $\frac{1}{f(D)}$  operating on  $f'(D)V_1$  and then  $\frac{1}{f(D)}$  on  $V_1$  which can be interpreted as  $f'(D)$  over  $f(D)$  whole square operating on  $V_1$ . So, we get this  $\frac{1}{f(D)}$  operating on  $xV_1$  then  $f'(D)$  over  $f(D)$  whole square operating on  $V_1$ . Now let us write the value of  $\frac{1}{f(D)} xV_1$  from here. So,  $\frac{1}{f(D)} xV_1$  is  $x$  times  $\frac{1}{f(D)}$  operating on  $V_1$  minus  $f'(D)$  over  $f(D)$  whole square operating on  $V_1$ . And hence  $\frac{1}{f(D)}$  operating on  $xV_1$  is nothing but  $x \frac{1}{f(D)}$  operating on  $V_1$ , and then this can be interpreted as derivative of  $\frac{1}{f(D)}$  with respect to  $D$ , like we differentiate  $\frac{1}{x}$  with respect to  $x$ . So, minus  $f'(D)$  over  $f(D)$  whole square can be interpreted as the derivative of  $\frac{1}{f(D)}$ . So, that is operated on  $V_1$ .

Now, let us see how we will apply this formula now here. One more thing this formula can since  $V_1$  is an arbitrary function,  $V$  for then arbitrary function. So,  $V_1$  is also arbitrary. So, we can write this formula for  $V$ . So,  $\frac{1}{f(D)}$  operating on  $V$ . So, we get the formula following formula  $V_1$  can be replaced by  $V$ . So,  $\frac{1}{f(D)}$  operating on  $x$  into  $V$  gives you  $x \frac{1}{f(D)}$  operating on  $V$ , and then  $\frac{d}{dD}$  over  $f(D)$  operating on  $\frac{1}{f(D)}$  operating on  $V$ . This is the formula now let us see how we shall apply this formula. So, let us look at the equation  $D^2 y - 2Dy + 1y = x \sin x$ .

So here let us find particular integral; so  $\frac{1}{D^2 - 2D + 1}$  operating on  $x \sin x$ . So, this is second-order non-homogeneous linear differential equation where  $r(x)$  is

$x \sin x$ . So, it is of the form  $x$  into  $V$  where  $V$  is  $\sin x$ . Now applying this formula  $\frac{1}{f(D)} x V$  equal to  $x \frac{1}{f(D)} V + \frac{d}{dD} \frac{1}{f(D)} V$ , we can write this as  $x \frac{1}{D^2 - 2D + 1} \sin x + \frac{d}{dD} \frac{1}{D^2 - 2D + 1} \sin x$ . This is equal to  $D^2 - 2D + 1$  can be replaced by  $(-1)^2 - 2(-1) + 1$ , so  $x \frac{1}{(-1)^2 - 2(-1) + 1} \sin x$ . So, we that  $(-1)^2 - 2(-1) + 1$  upon  $D^2 - 2D + 1$  whole square operating on  $\sin x$ , the derivative of  $\frac{1}{D^2 - 2D + 1}$  with respect to  $D$  we have written here.

Now, this is equal to  $\frac{1}{2D}$  operating on  $\sin x$ . So, we get  $\frac{1}{2} x \sin x$  then  $\frac{1}{2D} \sin x$  this means integral of  $\sin x$  which is  $-\cos x$ . And here we replace  $D^2$  by  $(-1)^2$  that is  $-1$ . So,  $(-1)^2 - 2(-1) + 1$  means  $0$ . So, we get  $(-1)^2 - 2(-1) + 1$  whole square which is  $4$ ; so we get  $\frac{1}{4} x \sin x$  and this will then be equal to  $\frac{1}{2} x \cos x - \frac{1}{2} \sin x$ . So, we can write  $\frac{1}{2} x \cos x - \frac{1}{2} \sin x$  and  $\frac{1}{2}$  becomes  $\frac{1}{2}$  by, so,  $\frac{1}{2}$  and then  $D - 1$  will operate on  $\sin x$  will give you  $\cos x - \sin x$ . So, this is particular integral in this case.

Now, this formula is generally avoided, because of the complicity of this formula. We use alternate method to determine the particular integral in case of the functions where we have  $x$  into  $V$ .

(Refer Slide Time: 08:16)

**Example.**

$$(D^2 - 2D + 1) y = x \sin x.$$

Here in this example, the particular integral will be

$$y_p(x) = \frac{1}{2}(x \cos x + \cos x - \sin x).$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 5

(Refer Slide Time: 08:20)

$$\begin{aligned}
 P.I. &= \frac{1}{D^2 - 2D + 1} x \sin x \\
 &= \text{Im part of } \frac{1}{D^2 - 2D + 1} x (\cos x + i \sin x) \\
 &= \text{Im part of } \frac{1}{D^2 - 2D + 1} x e^{ix} \\
 &= \text{Im part of } \left[ e^{ix} \frac{1}{(D+i-1)^2} x \right] \quad \text{let } i-1 = \alpha \Rightarrow \alpha^2 = -2i \\
 &= \text{Im part of } \left[ \frac{e^{ix}}{\alpha^2} \left(1 + \frac{D}{\alpha}\right)^{-2} x \right] = \text{Im} \left[ \frac{e^{ix}}{-2i} \left(1 - \frac{2D}{\alpha}\right) x \right] \\
 &= \frac{1}{2} \left\{ x \cos x + \cos x - \sin x \right\} \\
 &= -\frac{1}{2} x (-\cos x) - \frac{(D-2) \sin x}{4(-1)} \\
 &= \frac{1}{2} x \cos x + \frac{1}{2} (\cos x - \sin x)
 \end{aligned}$$

So, let us see alternate method here. So, let us find particular integral by an alternate method. What we do is we can write it as imaginary part of 1 over D square minus 2 D plus 1 operating on x times cos x plus i sin x, x sin x is imaginary part of x times cos x plus i sin x.

Now, this is equal to imaginary part of 1 over D square minus 2 D plus 1 operating on e to the power i x because e to the power i x is cos x plus i sin x. Now let us apply the formula 1 over f D operating on e to the power i x into V. So, that formula would be apply we get this is D minus 1 whole square D is replaced by D plus i. So, we get D plus i minus 1 whole square operating on x let us assume that let us say i minus 1 is equal to some alpha. So, alpha if we assume then this is e to the power i x by alpha square 1 plus D by alpha is to the power minus 1.

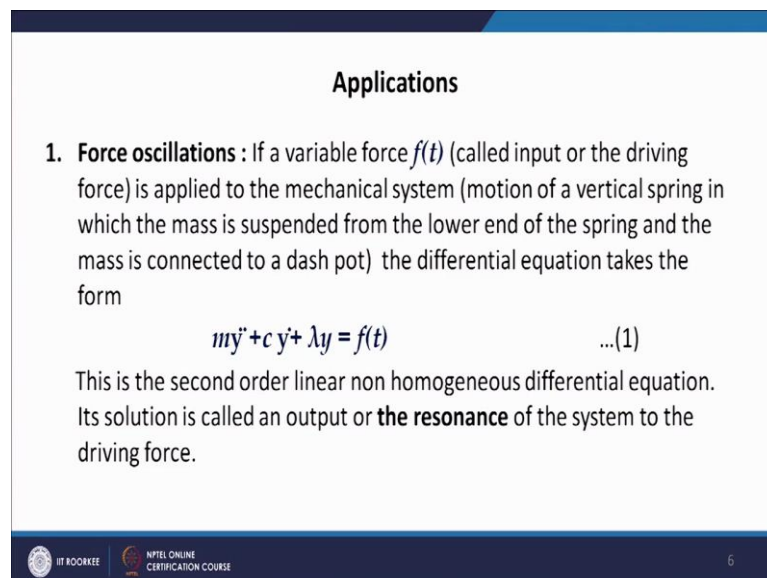

Since the power of x is 1. Here when we extend 1 plus D by alpha to the power minus 2 we just retain the power of D as 1. Because the D square when operates on x it will give us 0. So, this is imaginary part of e to the power i x alpha square will be equal to i minus 1 whole square which is i square plus 1 minus 2 i. So, this is minus 2 i.

So, we get e to the power minus i x over minus 2 i and then 1 plus D by alpha minus 2 will give you 1 minus 2 D by alpha. We are not writing higher powers of D operating on x. So, this will be equal to imaginary part of, So, x minus 2 upon alpha now this is equal to imaginary part of cos x plus i sin x divided by minus 2 y into x minus 2 upon i minus

1. So, when you simplify this expression write it as a complex number alpha plus say a plus i V, and then take the imaginary part you will get half of x cos x plus half of cos x minus sin x. So, we get half of x cos x plus cos x minus sin x. So, this is an alternate method of obtaining the particular integral for functions of the type x into V.

Now let us discuss an application. We had earlier discussed an application in mechanics where we had homogeneous linear differential equation of second-order. Now, we are doing considering an application where we will have a non-homogeneous linear differential equation of second-order.

(Refer Slide Time: 12:25)

**Applications**

**1. Force oscillations :** If a variable force  $f(t)$  (called input or the driving force) is applied to the mechanical system (motion of a vertical spring in which the mass is suspended from the lower end of the spring and the mass is connected to a dash pot) the differential equation takes the form

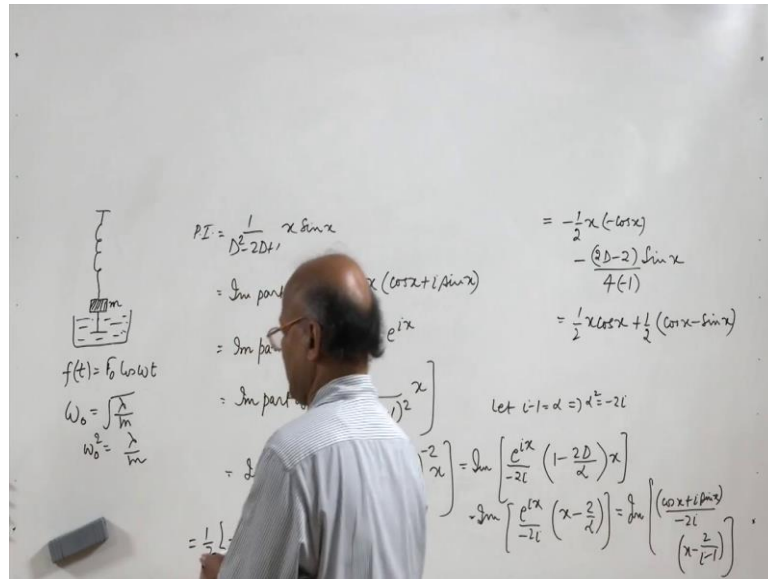

$$m\ddot{y} + c\dot{y} + \lambda y = f(t) \quad \dots(1)$$

This is the second order linear non homogeneous differential equation. Its solution is called an output or **the resonance** of the system to the driving force.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 6

So, let us discuss force oscillations. In the force oscillations we apply a variable force which we call which we can denote by  $f(t)$ ,  $t$  is the time variable it is called input or the driving force. It is applied to the mechanical system, the mechanical system which we had considered earlier in the case of homogeneous linear differential equation of second-order.

(Refer Slide Time: 12:43)

We had considered a particular spring, and with the fix support and then mass  $m$  is suspended from the lower end of the spring. Spring and then it is attached to a dead spot, it is attached to a dead spot filled with a viscous liquid.

So, the differential equation now when we apply the variable force  $f t$ , will be of the form  $m y$  double dot plus  $c y$  dot plus  $\lambda y$  equal to 0 in this absence of this variable force  $f t$  we had obtained the second-order differential equation homogeneous  $m y$  double dot plus  $c y$  dot plus  $\lambda y$  equal to 0. So, now, this is second-order linear non-homogeneous differential equation. Its solution will be called an output are the resonance of the system to the driving force.

(Refer Slide Time: 13:56)

Here the case of a periodic driving force is of a special interest. The sinusoidal input is given by

$$f(t) = F_0 \cos \omega t, \quad (F_0 > 0, \omega > 0).$$

Particular integral of equation (1)  $= y_p(t) = a_1 \cos \omega t + a_2 \sin \omega t$ ,

where

$$a_1 = \frac{m(\omega_0^2 - \omega^2)}{m^2(\omega_0^2 - \omega^2)^2 + \omega^2 c^2} F_0 \quad \text{and} \quad a_2 = \frac{\omega c}{m^2(\omega_0^2 - \omega^2)^2 + \omega^2 c^2} F_0,$$
$$\omega_0 = \sqrt{\frac{\lambda}{m}}.$$

IT Roorkee | NPTEL ONLINE CERTIFICATION COURSE | 7

Now, in the case of this non-homogeneous differential equation, we generally consider periodic driving force, but it has a special interest, we have interest specially interest in So, let us considered  $f(t)$  to be equal to  $F \cos \omega t$  where  $F$  is positive  $\omega$  is positive, then the particular integral. So, when you take  $f(t)$  equal to  $F \cos \omega t$ , then particular integral will come out to be  $a_1 \cos \omega t + a_2 \sin \omega t$ .

We can check it very easily the particular integral will come out to be  $a_1 \cos \omega t + a_2 \sin \omega t$  where  $a_1$  is equal to this and  $a_2$  equal to this. And  $\omega_0$  is the root  $\lambda/m$  the natural frequency. Now provided the denominator is non 0, the denominator here this denominator is non 0, we get this  $y_p(t)$  equal to  $a_1 \cos \omega t + a_2 \sin \omega t$ .

(Refer Slide Time: 14:54)

Provided the denominator is non-zero.  
The general solution is

$$y(t) = y_h(t) + y_p(t),$$

where  $y_h(t)$  is the complementary function of the homogeneous equation associated to equation (1) and is given by

Now, the general solution as we know the general solution will when be the sum of the complementary function, which is the general solution of the homogeneous linear differential equation and the particular integral  $y_p t$ . So, this is the complementary function of the homogeneous equation associated to equation 1.

(Refer Slide Time: 15:09)

**Case 1. When  $c^2 > 4m\lambda$  (over damping)**  
then  $y(t) = c_1 e^{-(p-q)t} + c_2 e^{-(p+q)t}$ , ... (2)

where  $p = \frac{c}{2m}$  and  $q = \frac{1}{2m} \sqrt{c^2 - 4m\lambda}$ .

**Case 2. When  $c^2 < 4m\lambda$  (under damping)**  
then  $y(t) = e^{-pt} (A \cos \bar{\omega} t + B \sin \bar{\omega} t)$   
 $= c e^{-pt} \cos(\bar{\omega} t - \delta)$ , ... (3)

where  $q = i \bar{\omega}$ ,  $\bar{\omega} = (1/2m) \sqrt{4m\lambda - c^2}$ .

Now, let then in the case of free oscillations, we had 3 cases when  $c$  square is greater than  $4 m \lambda$ . We had over damping  $y t$  came out to be this where  $p$  we had taken as  $c$  by  $2 m$   $q$  equal to this and then we had the second case  $c$  square less than  $4 m \lambda$

which was the case of under damping because  $c$  is the damping constant. So, we had the solution  $y(t)$  equal to  $c$  times  $e^{-\lambda t} \cos(\omega t)$ . And the  $\omega$  was equal to  $\sqrt{\lambda^2 - c^2}$ .

(Refer Slide Time: 15:44)

**Case 3. When  $c^2 = 4m\lambda$  (Critical damping)**  
then  $y(t) = (a + bt)e^{-\lambda t}$ . ... (4)

**Forced oscillations without damping:**  
In this case  $c = 0$  and hence the solution becomes

$$y(t) = c \cos(\omega_0 t - \delta) + \frac{F_0}{m(\omega_0^2 - \omega^2)} \cos \omega t.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

Now, in the third case the critical damping when  $c^2$  becomes  $4m\lambda$ , we had  $y(t)$  equal to  $a + bt$  times  $e^{-\lambda t}$ . So, these are the solutions of the associated homogeneous equation. Now forced oscillations without damping first we have considered the case of forced oscillation without damping; that means, the damping constant  $c$  is equal to 0, and then the solution will take the form  $y(t) = c \cos(\omega t - 1)$ , we can see it from here  $y(t) = y_h(t) + y_p(t)$ ,  $y_h(t) + y_p(t)$  we are found  $y_p(t)$  as  $a_1 \cos \omega t + a_2 \sin \omega t$ . So, in that you put  $c$  equal to 0 you get the value of  $y_p(t)$ .

(Refer Slide Time: 16:32)

**Case 3.** When  $c^2 = 4m\lambda$  (Critical damping)  
then  $y(t) = (a + bt) e^{-pt}$ . ... (4)

**Forced oscillations without damping:**  
In this case  $c = 0$  and hence the solution becomes

$$y(t) = c \cos(\omega_0 t - \delta) + \frac{F_0}{m(\omega_0^2 - \omega^2)} \cos \omega t.$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 10

And  $y(t)$  comes out to be  $\frac{F_0}{m(\omega_0^2 - \omega^2)} \cos \omega t$ . And when  $c$  is 0  $c^2$  if you look at this  $c^2$  is 0 then  $c^2$  will be 0. So, 0 will be less than  $4m\lambda$  and therefore,  $y(t)$  will be equal to  $c e^{-pt} \cos(\omega_0 t - \delta)$ . So, we will get this as  $c$  times because  $p$  is equal to 0 here. This  $p$  is equal to 0 because  $c = 0$ . So, we get  $c$  times  $\cos(\omega_0 t - \delta)$ .

So, we get  $y(t)$  equal to  $c \cos(\omega_0 t - \delta)$  and then  $\frac{F_0}{m(\omega_0^2 - \omega^2)} \cos \omega t$  in the case  $c = 0$ . Now here this is a superposition of 2 harmonic oscillations. This is harmonic oscillation and this is also harmonic oscillation. So, we get a superposition of 2 harmonic oscillations with frequencies  $\frac{\omega_0}{2\pi}$  here the frequency is  $\frac{\omega_0}{2\pi}$ , here the frequency is  $\frac{\omega}{2\pi}$  which comes from the driving force.

(Refer Slide Time: 17:35)

This is a superposition of two harmonic oscillations of frequencies  $\frac{\omega_0}{2\pi}$  of free oscillations and  $\frac{\omega}{2\pi}$  of the driving force.

The amplitude is given by 
$$a_0 = \frac{F_0}{\lambda} \frac{\omega_0^2}{\omega_0^2 - \omega^2},$$

which tends to  $\infty$  as  $\omega \rightarrow \omega_0$ .

Hence, if the frequency of the periodic driving force equals to the natural frequency of the system, the oscillations become too large.

This is **the case of resonance**.

IT Roorkee | NPTEL ONLINE CERTIFICATION COURSE | 11

The amplitude is given by a naught; the amplitude is given by this one. This amplitude F naught over m times omega naught square minus omega square. Since lambda y m equal to omega naught square, we have taken omega naught equal to square root lambda y m or omega naught square equal to lambda y m. So, from here if you substitute the value of m in the expression this one in the expression F naught over m times omega naught square minus omega square when you substitute the value of m, from the relation this one, omega naught square equal to lambda y m we get F naught y lambda omega naught square y omega naught.

Now this we can see from here as omega tends to omega naught, this a naught tends to infinity. So, amplitude becomes very large. Hence if the frequency of the periodic driving force omega equals the natural frequency omega naught, the oscillation becomes too large. So, this case is the case of resonance. The differential equation in the case of resonance then become if you look at the differential equation, these are my differential equation. We are taking c equal to 0.

(Refer Slide Time: 19:00)

The differential equation in case of resonance

$$\ddot{y} + \omega_0^2 y = \frac{F_0}{m} \cos \omega_0 t.$$

Its general solution is

$$y(t) = c \cos(\omega_0 t - \delta) + \frac{F_0 t \sin \omega_0 t}{2m\omega_0}.$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 12

So,  $m \ddot{y} + \lambda y = f t$ . This equation will then turn into this equation, using the relation  $\omega_0^2 = \lambda / m$ . We can write it as  $\ddot{y} + \omega_0^2 y = \frac{F_0}{m} \cos \omega_0 t$ . And its general solution is then  $y(t) = c \cos(\omega_0 t - \delta) + \frac{F_0 t \sin \omega_0 t}{2m\omega_0}$ .

We know how to determine the solution of the differential equation particular integral here will be,  $\frac{1}{D^2 + \omega_0^2}$  operating on  $\cos \omega_0 t$  and we know the formula for that. So, we can make use of that formula  $\frac{1}{D^2 + c^2}$  operating on  $\cos c x$ , we have  $\cos \omega_0 t$  that we have found as  $\frac{x \sin c x}{2c}$ . So, make use of this formula to get the particular integral this one,  $\frac{F_0 t \sin \omega_0 t}{2m\omega_0}$ .

(Refer Slide Time: 19:55)

**Forced oscillations with damping:**  
In this case  $c > 0$ , and from the equations (2)- (4), we find that  
$$y_h(t) \rightarrow 0, \text{ as } t \rightarrow \infty.$$
Hence after a sufficiently long time, the response to the sinusoidal input is given by  $y_p(t)$ .  
This is known as steady-state solution. In this case, the oscillations of the output have approximately the same frequency as that of the sinusoidal input after a lapse of sufficient time.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 13

Now, force oscillation with damping. So, here in this case  $c$  will be positive and from the equations 2 to 4 let us look at the equations 2 to 4 here.

(Refer Slide Time: 20:07)

**Case 1. When  $c^2 > 4m\lambda$  (over damping)**  
then 
$$y(t) = c_1 e^{-(p-q)t} + c_2 e^{-(p+q)t}, \quad \dots(2)$$
where 
$$p = \frac{c}{2m} \quad \text{and} \quad q = \frac{1}{2m} \sqrt{c^2 - 4m\lambda}.$$
  
**Case 2. When  $c^2 < 4m\lambda$  (under damping)**  
then 
$$y(t) = e^{-pt} (A \cos \bar{\omega} t + B \sin \bar{\omega} t)$$
$$= c e^{-pt} \cos (\bar{\omega} t - \delta), \quad \dots(3)$$
where 
$$q = i \bar{\omega}, \quad \bar{\omega} = (1/2m) \sqrt{4m\lambda - c^2}.$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 9

So, in this case when damping is present, then we have there arise 3 cases corresponding to the discriminant  $c^2$  greater than  $4m\lambda$ ,  $c^2$  less than  $4m\lambda$ , then  $c^2$  is equal to  $4m\lambda$ . In all the 3 cases you can see that  $y(t)$  tends to 0, because when  $q$  is less than  $p$ ,  $q$  is  $\frac{1}{2m} \sqrt{c^2 - 4m\lambda}$ . So,  $q$  is less than  $p$ . So, this  $p - q$  is positive. So, when  $t$  tends to infinity this goes to 0 this also

goes to 0 and here, when  $t$  goes infinity  $e^{-\alpha t}$  goes to 0 and  $\cos(\omega_b t - \delta)$  is bounded. So, this is tending to 0.

And here also when  $t$  tends to infinity because of the exponential function  $y_t$  goes to 0. So, now, the  $y_t$  there is nothing but the complementary function because  $y_t$  is the general solution of the associated homogeneous linear differential equation. So,  $y_t$  is  $y_h t$ . So,  $y_h t$  goes to 0  $y_p t$  goes to infinity. Hence after a sufficient sufficiently long time the response to the sinusoidal input is given by  $y_p t$ , because  $y_h t$  term tends to 0. So,  $y_t$  is nothing but  $y_p t$  this is known as the steady state solution in this case the oscillations of the output have approximately the same frequency as that of the sinusoidal input after a lapse of sufficient time.

So, with this I will come close this lecture.

Thanks.
