Construction of Green's Function-1

Hello friends in this lecture we are going to discuss construction of Green function and its application in converting linear differential equation into integral equation and in some condition we are able to solve completely the given differential equation. So let us start so before going to start with actual function of greens function we first discuss some basic thing about adjoint operator.

(Refer Slide Time: 0:58)

The Adjoint Operator

Let L be the differential operator $L := a(x)\frac{d^2}{dx^2} + b(x)\frac{d}{dx} + c(x)$. One may introduce the formal adjoint operator L^* , associated with L , is to form the product vLu , and integrate it over the interval of interest, by means of repeated integration by parts, the result can be expressed as

$$\int_a^b vLudx = [\dots]_a^b + \int_a^b uL^*vdx \quad (1)$$

here the functions u and v are understood to be completely arbitrary except that Lu and L^*v are defined.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So for adjoint operator the idea is that let we have L be the differential operator L which is defined as $a \times d^2 dx \text{ square} + b \times d \text{ by } dx + c \times x$. And here this u and v are considered as say some completely arbitrary only requirement here is that this Lu and L^*v exist, okay.

(Refer Slide Time: 1:20)

Example

Consider the general linear second order differential operator

$$L = a(x)\frac{d^2}{dx^2} + b(x)\frac{d}{dx} + c(x) \quad (2)$$

we have

$$\begin{aligned} \int_a^b vLudx &= \int_a^b (vau'' + vbu' + vcu)dx \\ &= (vau' + vbu)' \Big|_a^b + \int_a^b [-(va)'u' - (vb)'u + vcu]dx \\ &= [vau' + vbu - (va)'u] \Big|_a^b + \int_a^b [(va)''u - (vb)'u + vcu]dx \\ &= [avu' - (av)'u + bvu] \Big|_a^b + \int_a^b u[(av)'' - (bv)' + cv]dx \quad (3) \end{aligned}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

Now here we are considering this particular example so here if you look at we just multiplying v and integrating with respect to say some interval a to b where a and b are some interval where we want to perform this operation, if you look at here this is done say integration by part we have done once. So here if you look at this vau double dash and integrate by part we will get this vau dash and if we plus a to b minus va dash u dash and if you perform integration by part on this vbu dash you will get this vbu and minus integration of a to b vb dash u.

So if we do it all this calculation we will get this, so this is the boundary condition evaluated at the boundary point a to b and this is the integral.

(Refer Slide Time: 2:12)

comparing (1) and (3), we may defined the adjoint operator as

$$L^*v = (av)'' - (bv)' + cv = a\frac{d^2v}{dx^2} + (2a' - b)\frac{dv}{dx} + (a'' - b' + c)v \quad (4)$$

so that

$$L^* = a\frac{d^2}{dx^2} + (2a' - b)\frac{d}{dx} + (a'' - b' + c). \quad (5)$$

In the case that $L^* = L$, we say that L is formally self adjoint.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Here we have seen that corresponding to differential operator L we have defined adjoint operator defined as this L^* given as $(av)'' - (bv)'$ plus c of v and if we expand this expression we are going to have this thing equation number 4 that $(av)''$ plus $2a$ dash minus b v dash plus a double dash minus b dash plus c . Now here in the case when this L^* is same as L we call this operator as self adjoint operator.

(Refer Slide Time: 3:00)

$$L u = a u'' + b u' + c u.$$

$$L^* v = (a v)'' - (b v)' + c v.$$

$$= a v'' + (2a' - b) v' + c v.$$

$$L^* = L \Rightarrow L^* u = L u.$$

$$\Rightarrow \begin{aligned} a &= a && \text{coeff of } u'' \\ 2a' - b &= b && \text{coeff of } u' \\ &&& \text{coeff of } u. \end{aligned}$$

$$L u = a u'' + b u' + c u.$$

$$L^* v = (a v)'' - (b v)' + c v.$$

$$= a v'' + (2a' - b) v' + (a'' - b' + c) v.$$

$$L^* = L \Rightarrow L^* u = L u.$$

$$L^* = L.$$

$$\Rightarrow \begin{aligned} a &= a && \text{coeff of } u'' \\ 2a' - b &= b && \text{coeff of } u' \\ a'' - b' + c &= c && \text{coeff of } u. \end{aligned}$$

$$a'' = b' \Rightarrow c = c.$$

$$L u = a u'' + a' u' + c u.$$

$$L u = \frac{d}{dx}(a u') + c u.$$

L is a self adjoint operator.

So what it means that let us say that L of u is defined as au double dash plus bu dash plus cu and and calculation we we have this L^* v as $(av)''$ minus $(bv)'$ plus cv and if you simplify this you will get $(av)''$ plus $2a$ dash minus b v dash plus c of v . Now if you say that this L^* is same as L this implies that that this this implies that L^* operating on u is same as L of u , this implies that your coefficient of u double dash is basically if you

compare this this with this you say that a is equal to a, so this is the coefficient of u double dash and if you look at the coefficient of u dash then it is basically here we have 2a dash minus b and here we have say b and if you look at coefficient of u then here we have this is the problem here here it is here it is a double dash minus b dash plus c.

So here if you look at the coefficient of u we have a double dash minus b dash plus c which is given as c here and if you look at if you solve this then here we get what here we get that a dash is equal to b. If you use this condition a dash equal to b then this is nothing but a double dash minus b dash is simply going to be 0, so this imply that c equal to c. So it means that when we assume a dash equal to b then this is trivially true.

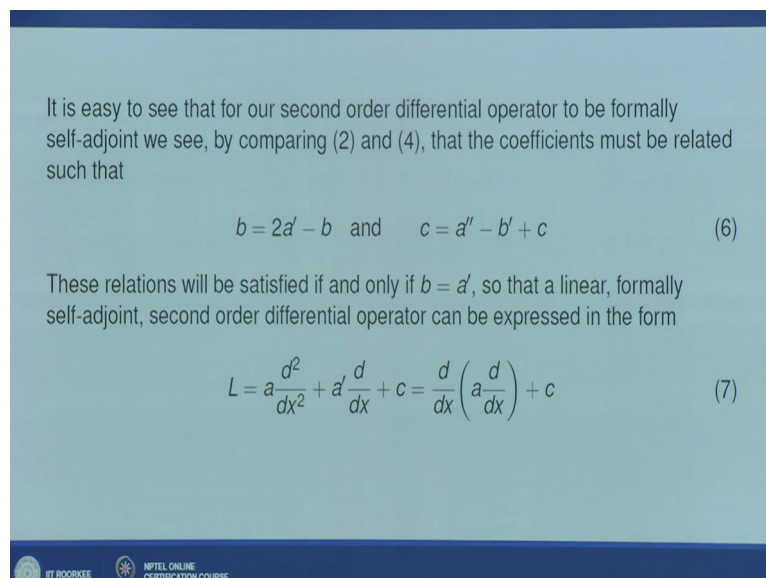

So it means that in the case of when when we have L star is equal to L or we can say that we have a self adjoint operator then we can write our Lu as this that au double dash plus now b is your a dash, so it is a dash u plus c of u (dash). So here I can rewrite this as d of dx of au dash plus c of u. So this is the this form of operator L is known as self adjoint form. So we say that here L is the self adjoint form we do not say that it is the we say that L is a self adjoint operator defined as this.

(Refer Slide Time: 6:10)

It is easy to see that for our second order differential operator to be formally self-adjoint we see, by comparing (2) and (4), that the coefficients must be related such that

$$b = 2a' - b \quad \text{and} \quad c = a'' - b' + c \quad (6)$$

These relations will be satisfied if and only if $b = a'$, so that a linear, formally self-adjoint, second order differential operator can be expressed in the form

$$L = a \frac{d^2}{dx^2} + a' \frac{d}{dx} + c = \frac{d}{dx} \left(a \frac{d}{dx} \right) + c \quad (7)$$

Now this we have seen that when b equal to a dash then we call this L operator as self adjoint operator and in this particular case your L can be written as d by dx of a d dx plus c.

(Refer Slide Time: 6:28)

Loaded String

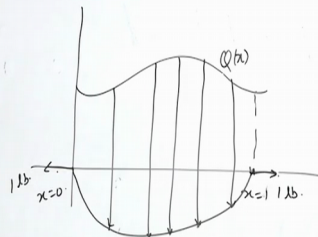

Consider the boundary value problem

$$u''(x) = \phi(x); \quad u(0) = u(1) = 0 \quad (8)$$

Where $\phi(x)$ is a given function.
 Here the function $u(x)$ may be regarded as the static deflection of the string, stretched under unit tension between fixed end points, and subjected to a force distribution $\phi(x)$ pounds under unit length.
 Our starting point, in the solution of (8) by the method of Green's functions, is equation (1) with v replaced by G , the so called "Green's function".

$$\int_0^1 GLud\xi = [\dots]_1^0 + \int_0^1 uL^*Gd\xi \quad (9)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

$\mathcal{L}u := u'' \Rightarrow \mathcal{L}u = \phi$
 $u(0) = 0 = u(1)$

$\Rightarrow \underline{\mathcal{L}^*} \mathcal{L}u = \mathcal{L}^* \phi$

$\Rightarrow u = \mathcal{L}^* \phi = \int_0^1 G(\xi, x) \phi(\xi) d\xi$
 $\Rightarrow u(x) = \int_0^1 G(\xi, x) \phi(\xi) d\xi$

$G(\xi, x)$ as kernel of \mathcal{L}^*
 known as Green's function.

Now let us come to construction of Green function, so we initiate we take an example of one boundary value problem given as $u''(x) = \phi(x)$ with the boundary condition that $u(0) = 0$ and $u(1) = 0$, where $\phi(x)$ is some given function. Now here we may consider $u(x)$ as say static deflection of the string and this string is stretched under unit tension between fixed end points and here we are putting this $\phi(x)$ as a force distribution under unit length.

Here we can write like this, so here we have $x = 0$ and here we say that $x = 1$ and between this to fixed end we have string attached here and we have a force say $\phi(x)$, right force distribution and it is acting on this string and here we are have a this is unit length.

So now we try to find out the solution of this particular problem $u'' = \phi$ with $u(0) = 0$ and $u(1) = 0$.

So we may try to find out the solution using variation of parameter method but here we try to solve it in a different context. So here we try to solve this using Green's function method. So if you look at the idea idea is something like this. Here we have this L of u which may be defined as u'' , is it okay. And when we define Lu as u'' , then this problem is given as $Lu = \phi$ with a condition that $u(0) = 0$ and $u(1) = 0$ and we try to find out the solution of this nonhomogeneous linear order in a differential equation.

So what we try to do is we try to operate another operator say L^* I am just denoting it by L^* which we operate on this so we will get what so we can write it like this. So L^* operating at Lu is same as writing $L^*\phi$. Now what we try to do is we try to define we need to find out L^* in a way such that L^*L is going to be identity or I can say that this L^* is going to be right inverse to this L so we write it like this. So here we simply say that u is going to be $L^*\phi$, right.

Now since this L is defined as a differential operator then we can consider we may consider that L^* is going to be an integral operator. So when we operate $L^*\phi$ on this ϕ we may write it like $\int_0^1 G(x, \xi) \phi(\xi) d\xi$, right. So here we say that this $L^*\phi$ is given as this integral thing. Now here I can say that this $G(x, \xi)$ is a kernel of this L^* and we call this $G(x, \xi)$ as kernel of L^* and commonly known as Green function Green's function.

So it means that if we can find out this Green function then we may find out our solution $u(x)$ given as this. So here we can write $u(x) = \int_0^1 G(x, \xi) \phi(\xi) d\xi$. So our aim is to find out this green function. So how to do it? So for that use this relation which is known as Green's formula.

(Refer Slide Time: 11:24)

$$\int_a^b u L u \, dx = \left[\int_a^b \right] + \int_a^b u L^* u \, dx.$$

$a=0, b=1 \quad v = G.$

$$\Rightarrow \int_a^b L u = L^* \phi.$$

$$\Rightarrow u = L^* \phi = \int_0^1 G(\xi, x) \phi(\xi) \, d\xi, \quad G(\xi, x) \text{ as kernel of } L^*$$

$$\Rightarrow u(x) = \int_0^1 G(\xi, x) \phi(\xi) \, d\xi. \quad \text{known Green's function.}$$

Loaded String

Consider the boundary value problem

$$u''(x) = \phi(x); \quad u(0) = u(1) = 0 \tag{8}$$

Where $\phi(x)$ is a given function.
 Here the function $u(x)$ may be regarded as the static deflection of the string, stretched under unit tension between fixed end points, and subjected to a force distribution $\phi(x)$ pounds under unit length.
 Our starting point, in the solution of (8) by the method of Green's functions, is equation (1) with v replaced by G , the so called "Green's function".

$$\int_0^1 G L u \, d\xi = \left[\dots \right]_1^0 + \int_0^1 u L^* G \, d\xi \tag{9}$$

6

So if you look at you remember this the process of finding adjoint operator what we have done here we have v of $Lu \, dx$ and we have written it some boundary terms between a to b if the limit is a to b plus here we have a to b and we have $u L^* v \, dx$. Now here in this particular case your a is 0 and b is equal to 1 . So what we try to do is we try to look at the same formula but now we simply say that v is replaced by this Greens function G .

So here we have seen that while defining the adjoint operator we have this relation that a to b $v Lu \, dx$ equal to boundary terms plus a to b $u L^* v \, dx$. For this particular problem we have a equal to 0 and b equal to 1 , what we try to do is we just replace our v by Green function G and try to solve this. So here we have 0 to 1 $GLud \, xi$ equal to boundary term between 0 to 1 and plus 0 to 1 $uL^* Gd \, xi$.

(Refer Slide Time: 12:46)

Here $L = d^2/d\xi^2$, we may obtain the boundary terms and adjoint operator by performing integration on the Left hand side of the equation

$$\int_0^1 G \phi d\xi = [G u' - u G_\xi]_0^1 + \int_0^1 u G_{\xi\xi} d\xi$$

$$\int_0^1 G(\xi, x) \phi(\xi) d\xi = G(1, x) u'(1) - u(1) G_\xi(1, x) - G(0, x) u'(0)$$

$$+ u(0) G_\xi(0, x) + \int_0^1 u(\xi) L^* G d\xi$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

$$\int_a^b u L u dx = \left[\right]_a^b + \int_a^b u L^* u dx$$

$$\int_0^1 G L u d\xi = \int_0^1 G u_{\xi\xi} d\xi$$

$$= G u_\xi \Big|_0^1 - \int_0^1 G_\xi u_\xi d\xi$$

$$= G u_\xi \Big|_0^1 - \left[G_\xi u \Big|_0^1 - \int_0^1 G_{\xi\xi} u d\xi \right]$$

$$= [G u_\xi - G_\xi u]_0^1 + \int_0^1 G_{\xi\xi} u d\xi$$

For this particular problem we have L as d^2/dx^2 and if you simplify this what you will get you will get here. So here we have 0 to 1 v which is replaced by G , so $G L u dx$ is equal to I am writing here 0 to 1 G and L is u_{xx} I am denoting here that variable is x here, so this I can write it as first integration of second so u_{xx} 0 to 1 minus 0 to 1 $G_{xx} u_{xx}$. If you perform one more time integration by part you will get $G u_x$ 0 to 1 minus here if you do $G_{xx} u$ between 0 to 1 minus 0 to 1 $G_{xx} u_{xx}$. If you simplify this you will get $G u_x$ minus $G_{xx} u$ evaluated between 0 to 1 plus 0 to 1 $G_{xx} u_{xx}$.

So it is written like this so here if we write down the boundary points here then we have $G(1, x) u_x(1) - u(1) G_x(1, x) - G(0, x) u_x(0) + u(0) G_x(0, x) + \int_0^1 u(\xi) L^* G d\xi$. So here if you remember we have u_{xx}

double dash is given by phi, so I am writing here phi in place of u double dash xi. So if you look at here than if we look at the boundary condition boundary condition is that u 1 is equal to 0 and u 0 is going to be 0.

So it means that these two term is going to drop out the only thing left here is this and this and if you look at this term I want that this should give the solution of the problem. So it means that use 0 to 1 u xi L star G d xi should somehow give the function u of x here.

(Refer Slide Time: 15:54)

If Green's function satisfies the BVP

$$L^*G = G_{\xi\xi}(\xi, x) = \delta(\xi - x) \quad (10)$$

$$G(0, x) = G(1, x) = 0, \quad (11)$$

then the solution of (8) is given by

$$u(x) = \int_0^1 G(\xi, x)\phi(\xi)d\xi. \quad (12)$$

Here $\delta(\xi - x)$ is a Dirac delta function. To find the solution $u(x)$ let us find the Green's function using (10-11).

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

Here $L = d^2/d\xi^2$, we may obtain the boundary terms and adjoint operator by performing integration on the Left hand side of the equation

$$\int_0^1 G\phi d\xi = [G\phi - uG_\xi]_0^1 + \int_0^1 uG_{\xi\xi} d\xi$$

$$\int_0^1 G(\xi, x)\phi(\xi)d\xi = G(1, x)u'(1) - u(1)G_\xi(1, x) - G(0, x)u'(0)$$

$$+ u(0)G_\xi(0, x) + \int_0^1 u(\xi)L^*Gd\xi$$

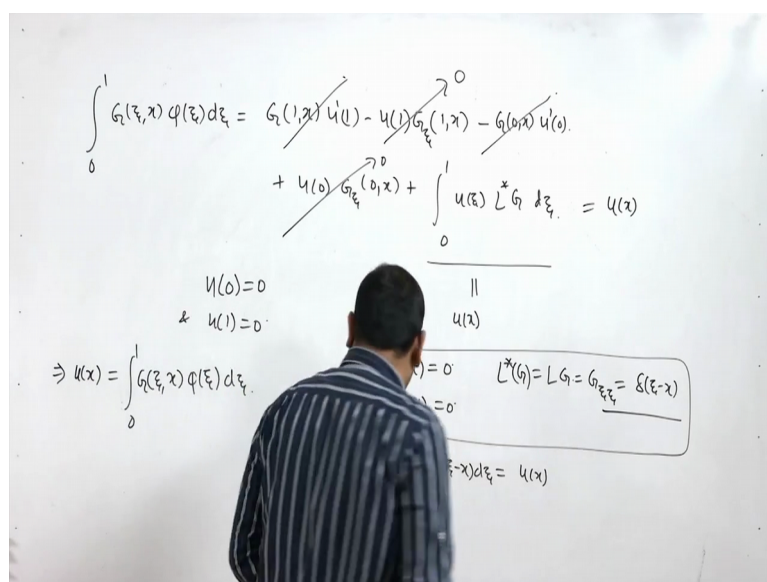

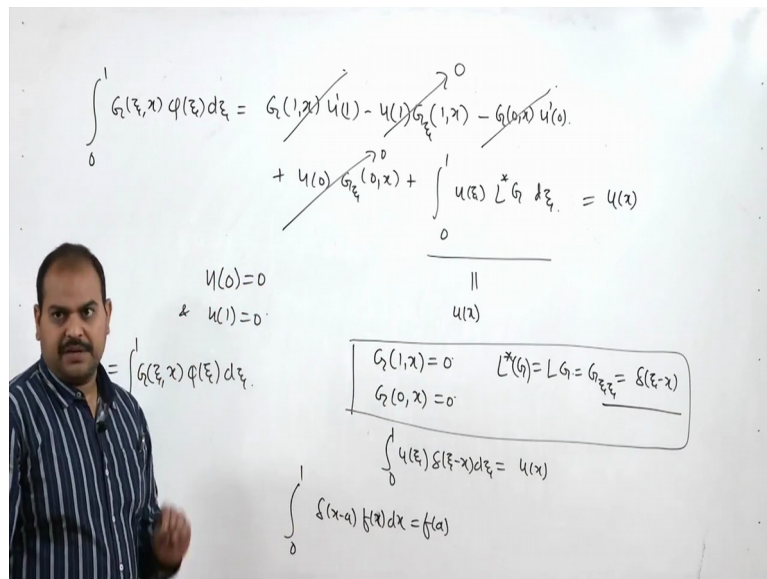

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

So to show that this will give you u of x here we assume that our Green function L star G is given by G xi xi xi, x here because here we are dealing with self adjoint operator so L star is nothing but same as L which is double derivative with respect to xi here, so G xi xi equal to

delta xi minus x. And the boundary condition just to make these two term vanish that G 1, x and G 0, x we are assuming that it is 0.

So this is an additional condition we are putting here that G Green function should satisfy this second order ordinary differential equation plus G 0, x equal to G 1, x given as 0. If we use this then this term last term this 0 to 1 u xi now this is what delta xi minus x.

(Refer Slide Time: 16:50)

So here delta is your Dirac delta function 0 to 1 G xi, x phi xi d xi equal to G 1, x u of 1 u dash 1 minus u 1 G xi 1, x minus G 0, x u dash 0 plus u of 0 G xi, 0 x plus 0 to 1 u xi L star which is same as L here G d xi. Now since we already have u 0 equal to 0 and u 1 equal to 0. So if we use this this condition is simply 0 and this is again going to be 0, right.

So now if we want that this will give us the solution here what we want is that we choose our G in a way such that this will give you u of x and $G(1, x)$ should be 0 so that no boundary term will be there and $G(0, x)$ is equal to 0. So here what we want is this this we can achieve by saying that if $L^* G$ which is same as $L G$ here so it is $G(\xi, \xi)$ here and we want that this should be given as $\delta(\xi - x)$.

So if we assume this then $\int_0^1 u(\xi) \delta(\xi - x) d\xi$ is going to be u of x , so here this is the filtering property we are assuming here that $\int_0^1 \delta(x - a) f(a) da = f(x)$ so here we are using the filtering property of Dirac delta function. So it means that if we assume our Green function which satisfy this equation that $G(\xi, \xi) = \delta(\xi - x)$ and satisfying these two boundary condition that $G(1, x) = 0$ and $G(0, x) = 0$ then this will also vanish and this is coming out to be u of x , so it is coming out to be u of x .

And we can rewrite this as u of x is equal to $\int_0^1 G(\xi, x) \phi(\xi) d\xi$. So this is our solution provided we should know what is G of ξ, x . So let us try to find out $G(\xi, x)$ with the this boundary value problem here and try to find out what is $G(\xi, \xi)$, okay.

(Refer Slide Time: 20:26)

If Green's function satisfies the BVP

$$L^* G = G_{\xi\xi}(\xi, x) = \delta(\xi - x) \quad (10)$$

$$G(0, x) = G(1, x) = 0, \quad (11)$$

then the solution of (8) is given by

$$u(x) = \int_0^1 G(\xi, x)\phi(\xi)d\xi. \quad (12)$$

Here $\delta(\xi - x)$ is a Dirac delta function. To find the solution $u(x)$ let us find the Green's function using (10-11).

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

So for that here just look at here here we these these are the Greens function satisfies these boundary conditions $L^* G$ equal to $G(\xi, \xi) = \delta(\xi - x)$ with the boundary condition and solution is given this, okay.

(Refer Slide Time: 20:40)

Integrating (10), with x regarded as fixed,

$$G_\xi = H(\xi - x) + A \quad (13)$$

$$G = (\xi - x)H(\xi - x) + A\xi + B \quad (14)$$

Using boundary conditions (11)

$$G(0, x) = 0 = 0 + 0 + B \quad (15)$$

$$G(1, x) = 0 = (1 - x) + A + B \quad (16)$$

Hence we get

$$G(\xi, x) = (\xi - x)H(\xi - x) + (x - 1)\xi \quad (17)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

$G_{\xi\xi} = \delta(\xi - x)$

$$\int_{\xi} G_{\xi\xi}(\xi, x) d\xi = \int \delta(\xi - x) d\xi$$

$$G_{\xi\xi}(\xi, x) = H(\xi - x) + A$$

$$G(\xi, x) = \int H(\xi - x) d\xi + A\xi + B \quad \checkmark \quad \int H(\xi - x) d\xi = (\xi - x)H(\xi - x)$$

$$G(\xi, x) = (\xi - x)H(\xi - x) + A\xi + B$$

$$= \begin{cases} \xi - x + A\xi + B & \xi > x \\ A\xi + B & \xi < x \end{cases}$$

$f(\xi) = H'(\xi)$

$$H(\xi) = \begin{cases} 1 & \xi > 0 \\ 0 & \xi < 0 \end{cases}$$

$G(0, x) = 0$
 $G(1, x) = 0$

$G_{\xi\xi} = \delta(\xi - x)$

$$\int_{\xi} G_{\xi\xi}(\xi, x) d\xi = \int \delta(\xi - x) d\xi$$

$$G_{\xi\xi}(\xi, x) = H(\xi - x) + A$$

$$G(\xi, x) = \int H(\xi - x) d\xi + A\xi + B \quad \checkmark \quad \int H(\xi - x) d\xi = (\xi - x)H(\xi - x)$$

$$G(\xi, x) = (\xi - x)H(\xi - x) + A\xi + B$$

$$G(0, x) = 0 = A \cdot 0 + B \quad \checkmark$$

$$G(1, x) = 0 = (1 - x)H(1 - x) + A \cdot 1 + B = 1 - x + A + B \Rightarrow B = 0$$

$u''(x) = q(x) \quad 0 < x < 1$
 $u(0) = 0 = u(1)$

$f(\xi) = H'(\xi)$

$$H(\xi) = \begin{cases} 1 & \xi > 0 \\ 0 & \xi < 0 \end{cases}$$

$G(0, x) = 0$
 $G(1, x) = 0$

Now if we look at this boundary condition your $G(x)$ is equal to $\delta(x - x)$, so we integrate with respect to x keeping x as fixed variable. So we are integrating this $G(x)$ equal to $(x) \delta(x - x)$. So here we integrate with respect to x keeping x as fixed, so $G(x) = \int_0^1 \delta(x - x) dx$ and if we recall here that this Dirac delta function $\delta(x)$ can be considered as derivative of Heaviside function.

So what is Heaviside function here? Here Heaviside function is defined as 1 when x is positive and 0 when x is less than 0. So we can find this in any of the standard text book of differential equation that $\delta(x)$ is defined as $H'(x)$, where $H(x)$ is a Heaviside function given defined as this. There is a small hint for this particular problem, so I can write this $\delta(x)$ as limit say ϵ tending to 0 I can write it here $\frac{H(x - \epsilon) - H(x + \epsilon)}{2\epsilon}$, right so here $x - \epsilon$ and $x + \epsilon$ minus $H(x - \epsilon)$ minus $H(x + \epsilon)$ divided by 2ϵ . So you can take this $\delta(x)$ as derivative of this.

So using this concept we can write this as $H(x - x) + \text{some constant } A$. Now so this is nothing but $G(x)$, x is given by this I am not putting the limit here 0 and 1 we simply integrating in a definite as definite integration, so that is why I am putting this as integration constant here. So now we want to we want to find out $G(x)$ only, so integrate one more time so we have $G(x)$ given as integration of $H(x - x) dx + Ax + B$. So this you can get this as $x - x H(x - x) + Ax + B$ so I can write it $G(x)$ is this.

So here I am using this this integration that $\int H(x - x) dx$ is given as $x - x H(x - x)$. So this you can proof as an simple exercise of Heaviside unit step function. So once we have $G(x)$ given in this particular form then using the definition of $H(x - x)$ I can write this as say this will activate when this argument of H is going to be positive, so it means that when x is greater than x we have $x - x + Ax + B$ and when we have x less than x we have $Ax + B$, right.

So here we have to how to find out this A and B for that we have condition given to us that $G(0) = 0$ and $G(1) = 0$. So if we operate if we use this two boundary condition then we can find out A and B how we can find out let us see, let me write it here then put $G(0) = 0$ then here when we put x as then this is going to be a negative then this will be as 0 and you can simply write it here as 0 times (sorry) this I can write it here $A \cdot 0 + B$.

Similarly $G(1, x)$ it is 0 here then we can write $1 - x$ and this $H(1 - x)$ here plus A into $1 + B$. Now look at here this $H(1 - x)$ whether it is positive or not. So if you remember your problem your problem is basically this $u'' = x$ and condition was $u(0) = 0 = u(1)$ here, so here your x is between 0 to 1. So it means that this $1 - x$ is going to be positive. So if $1 - x$ is going to be positive then this is going to be 1, so I can write it here this $1 - x$ plus A plus B here. So and that is going to be 0, so this I can write it here as $B = 0$ this implies that $B = 0$ which is clear from this and you can write here A as this $x - 1$.

(Refer Slide Time: 27:42)

The image shows handwritten mathematical work on a whiteboard. It defines the Green's function $G(\xi, x)$ as a piecewise function based on the relative values of ξ and x . It then uses this to express the solution $u(x)$ as an integral from 0 to 1 of $G(\xi, x) \phi(\xi) d\xi$.

$$G(\xi, x) = (\xi - x)H(\xi - x) + (x - 1)\xi$$

$$= \begin{cases} \xi - x + (x - 1)\xi & \xi > x \\ (x - 1)\xi & \xi < x \end{cases}$$

$$\textcircled{*} G(\xi, x) = \begin{cases} \xi x - x & \xi > x \\ (x - 1)\xi & \xi < x \end{cases} \Rightarrow \begin{cases} (\xi - 1)x & \xi > x \\ (x - 1)\xi & \xi < x \end{cases}$$

$$u(x) = \int_0^1 G(\xi, x) \phi(\xi) d\xi, \text{ where } G(\xi, x) \text{ is defined above by } \textcircled{*}$$

So I can write it here that $G(\xi, x)$ is defined as $\xi - x + (x - 1)\xi$ when $\xi > x$ and $(x - 1)\xi$ when $\xi < x$. Now again using the formula definition of $\xi - x + (x - 1)\xi$ I can write this as $\xi x - x$ when $\xi > x$ and $(x - 1)\xi$ when $\xi < x$ or you can simplify this further and it is what this is simply $\xi x - x$ when $\xi > x$ and $(x - 1)\xi$ when $\xi < x$.

So this I can further write in a different manner, so I can write $\xi x - x$ when $\xi > x$ and $(x - 1)\xi$ when $\xi < x$. So here our Green function is coming out to be this so if we remember our solution is going to be written as $u(x) = \int_0^1 G(\xi, x) \phi(\xi) d\xi$. So here where $G(\xi, x)$ is defined above we can say it is defined by this formula. So we can write it here $G(\xi, x) = \textcircled{*}$, so we can call this as star, so defined above by star.

So it means that our solution of the problem is given by this so we have seen that $u(x)$ is given by $\int_0^1 G(x, \xi) \phi(\xi) d\xi$ where $G(x, \xi)$ is defined above by this. So here so it means that I can write down the solution here once we know what is $\phi(x)$ here then we can write down this solution in this particular integral equation Fredholm integral equation.

(Refer Slide Time: 30:26)

The whiteboard contains the following handwritten text:

$$u''(x) = \phi(x) \quad u(0) = 0 = u(1)$$

$$L^* G = \delta(\xi - x), \quad L^* = \frac{d^2}{d\xi^2}, \quad G(\xi, x)$$

$$\Rightarrow G_{\xi\xi}(\xi, x) = \delta(\xi - x), \quad G(0, x) = 0 = G(1, x)$$

$$u(x) = \int_0^1 G(\xi, x) \phi(\xi) d\xi$$

Annotations on the whiteboard include:

- An arrow pointing from $G(\xi, x)$ to $G(\xi, x)$ in the integral.
- $\xi = x$ written next to the integral.
- $\phi(x) = \int_0^1 \delta(\xi - x) \phi(\xi) d\xi, \quad \xi = x$ written below the integral.
- A note: "where $G(\xi, x)$ is defined above by (*)"

Now here we have a very interesting interpretation of $G(x, \xi)$ if you remember here in the beginning we have started all this for solving this particular problem $u''(x) = \phi(x)$ and $u(0) = 0 = u(1)$ and here we simply said that this $u(x)$ is nothing but static deflection from the equilibrium position under the force $\phi(x)$. But when we calculate it our $G(x, \xi)$ then it is what it is basically $L^* G$ and we have $\delta(x - \xi)$, here L^* is given as d^2/dx^2 and G is nothing but $G(x, \xi)$.

So it means that it is given as $G(x, \xi) = \int_0^1 G(\xi, x) \phi(\xi) d\xi$ and with the condition that $G(0, x) = 0 = G(1, x)$. So here if I look at the same interpretation for this particular problem then I can consider as that $G(x, \xi)$ is basically deflection at a point x here when a unit force $\delta(x - \xi)$ is applied at the point $\xi = x$. So it means I can just repeating it one more time we consider that this $G(x, \xi)$ is denoting the deflection in string when your unit when unit force is applied at $\xi = x$.

So I can write that when we apply $G(x, \xi) \phi(\xi) d\xi$ then we can say this is the deflection in string for the force $\delta(x - \xi) \phi(\xi) d\xi$, right. So it means that I can consider that $G(x, \xi) \phi(\xi) d\xi$ is the deflection in string when you apply $\delta(x - \xi) \phi(\xi) d\xi$ force at point $\xi = x$. So this is the force we are acting at $\xi = x$.

Now this ξ is a variable point right now we are considering only the fixed point ξ equal to x . Now if we vary for every point between 0 to 1 we can say that this is the deflection this will represent the deflection if this is the force acting on the string. So this will represent your u of x and the force it is given as if you apply your filtering property then this is nothing but your ϕ of x , is it okay. So it means that $u(x)$ is going to be a deflection in your string if $\phi(x)$ is the force applying on the string per unit length. So that is the that maybe we can consider as a explanation for this $G(\xi, x)$.

So here in today's lecture in this lecture we have started the concept of Green's function and see that how we can solve a ordinary differential equation with the help of integral equation and if your function $\phi(\xi)$ is known to us then we can find out the complete solution, thanks for this lecture, thanks for listening us and in next lecture we will meet.
