Green's Function for Non-homogeneous Boundary Value Problem

Hello friends, so far we have discussed the construction of Green function for homogeneous boundary condition with homogeneous boundary value problem with homogeneous boundary conditions. Let us consider this non-homogeneous equation $p(x)y'' + p'(x)y' + q(x)y = f(x)$.

(Refer Slide Time: 0:41)

Use of Green's Function in the Solution of Nonhomogeneous Boundary Value Problems

Consider the following non-homogeneous equation

$$L[y] := p(x)y''(x) + p'(x)y'(x) + q(x)y(x) = f(x), \quad (1)$$

and the boundary conditions

$$V_1(y) := \alpha_1 y(a) + \beta_1 y'(a) = 0, \quad V_2(y) := \alpha_2 y(b) + \beta_2 y'(b) = 0, \quad (2)$$

where V_1 and V_2 are linearly independent. Also, Let y_1 and y_2 be two linearly independent solutions of $L(y) = 0$ such that $V_1(y_1) = 0$ and $V_2(y_2) = 0$ respectively.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

If you look at carefully this equation is given in terms of self adjoint form so this is a self adjoint equation and boundary condition also given as $V_1(y)$ and $V_2(y)$ and $V_1(y)$ is define at the point x equal to a and $V_2(y)$ is specified at the point x equal to b .

And here we have assumed that this V_1 and V_2 both are linearly independent, also we have assumed that we have 2 linearly independent solution of the homogeneous problem that is $L(y) = 0$ such that the first solution y_1 satisfy the condition given at point x equal to a and the second solution y_2 satisfy the boundary condition define at x equal to b .

(Refer Slide Time: 1:33)

Theorem

If $G(x, \xi)$ is a Green's function of the homogeneous boundary value problem (B.V.P.)

$$L[y] = 0, \quad (3)$$
$$V_k(y) = 0, \quad k = 1, 2. \quad (4)$$

Then $y(x)$ is a solution of the nonhomogeneous B.V.P. (1)-(2) if and only if

$$y(x) = \int_a^b G(x, \xi) f(\xi) d\xi. \quad (5)$$

Here

$$G(x, \xi) = \begin{cases} \frac{y_1(x)y_2(\xi)}{\rho(\xi)W(\xi)} := G_1(x, \xi), & a \leq x < \xi; \\ \frac{y_1(\xi)y_2(x)}{\rho(\xi)W(\xi)} := G_2(x, \xi), & \xi < x \leq b. \end{cases} \quad (6)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

And now with the help of this now we have this result which says that if $G(x, \xi)$ is a green function of the homogeneous boundary value problem Ly equal to 0 with the boundary condition $v_1 y$ equal to 0 and $v_2 y$ equal to 0 then $y(x)$ is a solution of the non-homogeneous boundary value problem 1 and 2 means this problem.

(Refer Slide Time: 1:56)

Use of Green's Function in the Solution of Nonhomogeneous Boundary Value Problems

Consider the following non-homogeneous equation

$$L[y] := p(x)y''(x) + p'(x)y'(x) + q(x)y(x) = f(x), \quad (1)$$

and the boundary conditions

$$V_1(y) := \alpha_1 y(a) + \beta_1 y'(a) = 0, \quad V_2(y) := \alpha_2 y(b) + \beta_2 y'(b) = 0, \quad (2)$$

where V_1 and V_2 are linearly independent. Also, Let y_1 and y_2 be two linearly independent solutions of $L(y) = 0$ such that $V_1(y_1) = 0$ and $V_2(y_2) = 0$ respectively.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

Theorem

If $G(x, \xi)$ is a Green's function of the homogeneous boundary value problem (B.V.P.)

$$L[y] = 0, \quad (3)$$

$$V_k(y) = 0, \quad k = 1, 2. \quad (4)$$

Then $y(x)$ is a solution of the nonhomogeneous B.V.P. (1)-(2) if and only if

$$y(x) = \int_a^b G(x, \xi) f(\xi) d\xi. \quad (5)$$

Here

$$G(x, \xi) = \begin{cases} \frac{y_1(x)y_2(\xi)}{\rho(\xi)W(\xi)} := G_1(x, \xi), & a \leq x < \xi; \\ \frac{y_1(\xi)y_2(x)}{\rho(\xi)W(\xi)} := G_2(x, \xi), & \xi < x \leq b. \end{cases} \quad (6)$$

So this is $Ly = f$ problem if and only if $y(x)$ is given by this expression $y(x) = \int_a^b G(x, \xi) f(\xi) d\xi$ where here your $G(x, \xi)$ is the green function of this homogeneous boundary value problem if you look at carefully this we have constructed in the previous lecture, so you remember here this $y_1(x)$ is a solution of the problem $Ly = 0$ and satisfying the boundary condition specified at the point $x = a$, similarly $y_2(x)$ is a solution of the problem $Ly = 0$ which satisfy the boundary condition specified at $x = b$.

And for our calculation purpose we have assumed that this is denoted as $G_1(x, \xi)$ and this is denoted as $G_2(x, \xi)$ and here the term in denominator that is $\rho(\xi)W(\xi)$ this is a basically a constant and it is independent of ξ and x that we can prove by this result.

(Refer Slide Time: 3:10)

Proof: Recall that the Green's formula for self adjoint operator

$$L(y) := (p(x)y')' + q(x)y$$

is given by

$$\int_a^x (vLu - uLv)dx = [p(x)(u'v - v'u)]_a^x \quad (7)$$

Now if u and v are two solutions of the operator L i.e. $Lu = Lv = 0$ then

$$\int_a^x (vLu - uLv)dx = 0 = [p(x)(u'v - v'u)]_a^x.$$

Let x be an arbitrary point in an interval of interest say $[a, b]$, then

$$p(x)W(x) = p(a)W(a) = \text{constant}.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So if you remember we have already discussed the Green's formula for this self adjoint operator so if we take the operator Ly which is defined as this self-adjoint form then we can define our Green's formula which is between a to x and it is given by vLu minus uLv dx equal to this quantity.

Now here if we take two u and v are two functions of the homogeneous problem that is Lu equal to Lv equal to 0 , then if you put u and v here as a solution of L operator L then this term becomes 0 so v into 0 minus u into 0 minus that becomes 0 . So this implies that this expression this expression is basically 0 and if you look at this expression we can say that $p(x)$ minus times W of x is equal to p of a minus times W of a or I can say this is that $p(x)W(x)$ equal to p of a W of a and since a is a fixed point we have we are taking so this is a constant value and x we can take any arbitrary point in this interval.

So we can say that this quantity $p(x)W(x)$ is always remain constant.

(Refer Slide Time: 4:36)

Let the relation (5) is true. Then using definition of Green function, we obtain

$$y(x) = \int_a^x G(x, \xi) f(\xi) d\xi + \int_x^b G(x, \xi) f(\xi) d\xi$$

$$= \frac{1}{A} \left[\int_a^x y_2(x) y_1(\xi) f(\xi) d\xi + \int_x^b y_2(\xi) y_1(x) f(\xi) d\xi \right] \quad (8)$$

where $A = p(x)W(x) = p(\xi)W(\xi) = \text{constant}$. On differentiation with respect to x , we get

$$y'(x) = \frac{1}{A} \left[\int_a^x y_2'(x) y_1(\xi) f(\xi) d\xi + \int_x^b y_1'(x) y_2(\xi) f(\xi) d\xi \right] \quad (9)$$

and

$$y''(x) = \frac{f(x) \cdot W(x)}{A} + \frac{1}{A} \left[\int_a^x y_2''(x) y_1(\xi) d\xi + \int_x^b y_1''(x) y_2(\xi) d\xi \right]$$

5

So using this expression that this result that $p(x)W(x)$ is constant we can write it $y(x)$ as this here y of x we have splitted into two interval a to x and x to b . So here in between a to x $G(x, \xi)$ is given by $y_2(x) y_1(\xi)$ divided by this A where it is defined as $p(\xi)W(\xi)$ but since we already know that $p(\xi)W(\xi)$ is a constant so we can write it some value in. So we are here we are assuming this A is denoting this constant value.

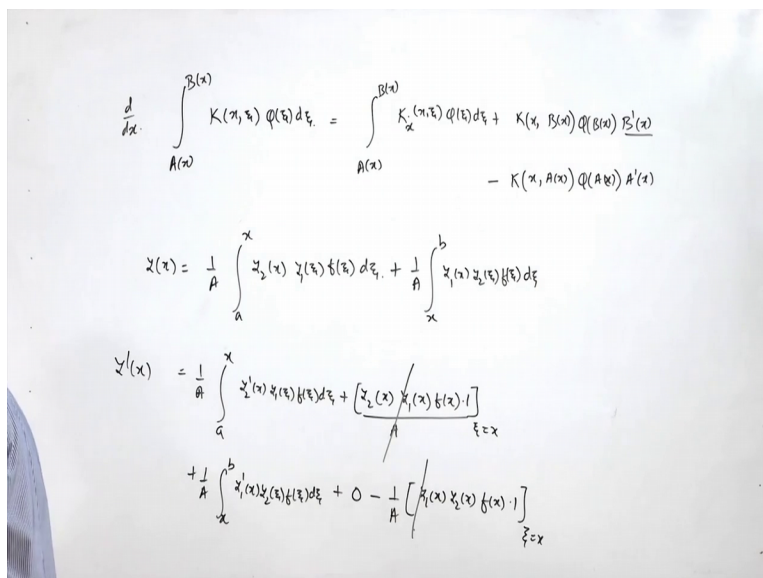

So between a to x we have written $G(x, \xi)$ equal to $y_2(x) y_1(\xi)$ and between x to b $G(x, \xi)$ is written as $y_2(\xi) y_1(x)$. Now here we want to show that this actually this actually satisfy the differential equation non-homogeneous differential equation for that we need to say that this $y(x)$ satisfy the non-homogeneous boundary value problem. So for that we simply calculate the derivative of this, so let us calculate the derivative here $y'(x)$ equal to this quantity here we are using the (5:50) formula for differentiation under this sign of integration I am just going to write that formula here.

(Refer Slide Time: 5:57)

So if we write $A(x)$ $B(x)$ here we have $K(x, \xi)$ your $\phi(\xi) d\xi$ and if we differentiate with respect to say d of with respect to x I can write it here as $A(x)$ $B(x)$ of x and differentiation of this with respect to x x, ξ $\phi(\xi) d\xi$ plus now take the upper limit say $B(x)$ so you take x in place of ξ in place of the variable integration variable you put this $B(x)$ so $B(x)$ of x here $\phi(B(x))$ here and the differentiation of this $B(x)$ dash x minus now in place of ξ you can write out the lower limit $A(x)$ of x $\phi(A(x))$ and $A(x)$ dash x here we are assuming that this $K(x, \xi)$ $\phi(\xi)$ and limit $A(x)$ and $B(x)$ all are continuous function with respect to x .

(Refer Slide Time: 7:23)

So this is a the formula which we are using to find out $y' x$ because if you look at using this formula let me write it here this is y of x just quickly I want to write it here so y of x is equal to $\frac{1}{x}$ upon A , A to x and here we have $y^2 x$ and $y^{-1} x$ $f(x) dx$ I will write only $\frac{1}{4}$, okay plus $\frac{1}{x}$ upon A similarly you can write it x to B and $y^{-1} x$ $y^2 x$ $f(x) dx$ I am going to write only for this rest you can say so it is $\frac{1}{x}$ upon A now if you look at this term simply say that between A to x since we have only this term for x so we simply write it $y^2 x$ $y^{-1} x$ $f(x) dx$ plus so there is no other term for x so we have differentiated only this $y^2 x$ plus if you look at this term then here the upper limit is x then if you can put here but when we take the derivative of upper limit that is going to be 0.

Sorry here I think it is x not x_i so let me, sorry this is x not x_i so if you take here this thing and if we take the derivative of this that is coming out to be y and if you look at this term then we have say $y^2 x$ $y^{-1} x$ sorry here lower limit is A so I am writing x_i as A so we simply write $y^{-1} A$ and f of A and if you find out say derivative of A with respect to x so that is going to be 0 here. So here this term is simply vanish and we have only this term left and similarly if we do it here we will get $\frac{1}{x}$ upon A here it is x to b $y^{-1} x$ now derivative of this means $y^{-1} x$ $y^2 x$ $f(x) dx$ plus use this term if you take this term then upper limit is b constant so this upper limit will simply vanish so we will consider only this lower limit.

So that is 0 here minus I will write it here $\frac{1}{x}$ upon A that thing I have left here A so this A here $\frac{1}{x}$ upon A I am writing here $y^{-1} x$ $y^2 x$ and f of x and here it is x here. So derivative of x is simply 1 it is this this is please correct this also this is x , okay is it okay here? Yeah. So between A to x we differentiated this using this same formula and we are getting this. Now if you look at this quantity is same as this quantity here basically it is at x_i equal to x so I am putting x_i equal to x here.

So this quantity will cancel each other and we have $y' x$ defined as 9. So here we have seen that this $y' x$ is given by this thing so $y' x$ is given by this, this will cancel out and $y' x$ is given by this. And you can say that it is given by this formula 9 so $y' x$ is given by this. Using the same formula you can define $y'' x$ and this now here the boundary condition so when you put take this term here when you consider the upper limit and here the lower limit and using the jump discontinuity of Green's function it is coming out to be this

quantity that $y''(x)$ is equal to $f(x)$ into $W(x)$ (11:39) of x divided by A plus this quantity.

(Refer Slide Time: 11:47)

If we form the combination $L(y) \equiv p(x)y''(x) + p'(x)y'(x) + q(x)y(x)$ (1), we obtain

$$Ly(x) = \frac{1}{A}[p(x) \cdot f(x) \cdot W(x)] + \frac{1}{A} \left[\int_a^x Ly_2(x)y_1(\xi)f(\xi)d\xi + \int_x^b Ly_1(x)y_2(\xi)f(\xi)d\xi \right] = f(x).$$

Now, we show that $y(x)$ satisfies the boundary conditions (2).
From equation (8) and (9), we obtain

$$y(a) = \frac{1}{A}y_1(a) \int_a^b y_2(\xi)f(\xi)d\xi,$$

$$y'(a) = \frac{1}{A}y_1'(a) \int_a^b y_2(\xi)f(\xi)d\xi,$$

It follows that y satisfies the same homogeneous conditions at $x = a$ as the function y_1 . Similarly, we can find $y(b)$ and $y'(b)$ and show that the boundary conditions (2) are satisfied.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

Now once we have your $y(x)$ then we can form this expression $Ly(x)$ which is $p(x)y''(x) + p'(x)y'(x) + Q(x)y(x)$ and we can calculate and this quantity $Ly(x)$ is coming out to be this and this is nothing but your $f(x)$ here we, yeah.

(Refer Slide Time: 12:12)

Theorem

If $G(x, \xi)$ is a Green's function of the homogeneous boundary value problem (B.V.P.)

$$L[y] = 0, \quad (3)$$

$$V_k(y) = 0, \quad k = 1, 2. \quad (4)$$

Then $y(x)$ is a solution of the nonhomogeneous B.V.P. (1)-(2) if and only if

$$y(x) = \int_a^b G(x, \xi)f(\xi)d\xi. \quad (5)$$

Here

$$G(x, \xi) = \begin{cases} \frac{y_1(x)y_2(\xi)}{p(\xi)W(\xi)} := G_1(x, \xi), & a \leq x < \xi; \\ \frac{y_1(\xi)y_2(x)}{p(\xi)W(\xi)} := G_2(x, \xi), & \xi < x \leq b. \end{cases} \quad (6)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

Use of Green's Function in the Solution of Nonhomogeneous Boundary Value Problems

Consider the following non-homogeneous equation

$$L[y] := p(x)y''(x) + p'(x)y'(x) + q(x)y(x) = f(x), \quad (1)$$

and the boundary conditions

$$V_1(y) := \alpha_1 y(a) + \beta_1 y'(a) = 0, \quad V_2(y) := \alpha_2 y(b) + \beta_2 y'(b) = 0, \quad (2)$$

where V_1 and V_2 are linearly independent. Also, Let y_1 and y_2 be two linearly independent solutions of $L(y) = 0$ such that $V_1(y_1) = 0$ and $V_2(y_2) = 0$ respectively.

So it means that if your G is given by expression 6 then the $y(x)$ equal to $\int_a^b G(x, \xi) f(\xi) d\xi$ will satisfy the non-homogeneous problem given by this $Ly = f(x)$.

The only remaining thing left is that it also satisfy the boundary condition specified at point a and b .

(Refer Slide Time: 12:39)

Let the relation (5) is true. Then using definition of Green function, we obtain

$$\begin{aligned} y(x) &= \int_a^x G(x, \xi) f(\xi) d\xi + \int_x^b G(x, \xi) f(\xi) d\xi \\ &= \frac{1}{A} \left[\int_a^x y_2(x)y_1(\xi) f(\xi) d\xi + \int_x^b y_2(\xi)y_1(x) f(\xi) d\xi \right] \end{aligned} \quad (8)$$

where $A = p(x)W(x) = p(\xi)W(\xi) = \text{constant}$. On differentiation with respect to x , we get

$$y'(x) = \frac{1}{A} \left[\int_a^x y_2'(x)y_1(\xi) f(\xi) d\xi + \int_x^b y_1'(x)y_2(\xi) f(\xi) d\xi \right] \quad (9)$$

and

$$y''(x) = \frac{f(x) \cdot W(x)}{A} + \frac{1}{A} \left[\int_a^x y_2''(x)y_1(\xi) f(\xi) d\xi + \int_x^b y_1''(x)y_2(\xi) f(\xi) d\xi \right]$$

If we form the combination $L(y) \equiv p(x)y''(x) + p'(x)y'(x) + q(x)y(x)$ (1), we obtain

$$Ly(x) = \frac{1}{A}[p(x) \cdot f(x) \cdot W(x)] + \frac{1}{A} \left[\int_a^x Ly_2(x)y_1(\xi)f(\xi)d\xi + \int_x^b Ly_1(x)y_2(\xi)f(\xi)d\xi \right] = f(x).$$

Now, we show that $y(x)$ satisfies the boundary conditions (2).
From equation (8) and (9), we obtain

$$y(a) = \frac{1}{A}y_1(a) \int_a^b y_2(\xi)f(\xi)d\xi,$$

$$y'(a) = \frac{1}{A}y_1'(a) \int_a^b y_2(\xi)f(\xi)d\xi,$$

It follows that y satisfies the same homogeneous conditions at $x = a$ as the function y_1 . Similarly, we can find $y(b)$ and $y'(b)$ and show that the boundary conditions (2) are satisfied.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

So for this you look at this equation, equation number 9 and if you put x equal to a then this integral will simply vanish and it is a to b y_1 dash a y_2 ξ f of ξ d ξ . So I can take y_1 dash a out and I can write expression as y dash a equal to 1 upon A y_1 dash a equal to y_1 dash a to b y_2 ξ f of ξ d ξ .

(Refer Slide Time: 13:06)

Let the relation (5) is true. Then using definition of Green function, we obtain

$$y(x) = \int_a^x G(x, \xi)f(\xi)d\xi + \int_x^b G(x, \xi)f(\xi)d\xi$$

$$= \frac{1}{A} \left[\int_a^x y_2(x)y_1(\xi)f(\xi)d\xi + \int_x^b y_2(\xi)y_1(x)f(\xi)d\xi \right] \quad (8)$$

where $A = p(x)W(x) = p(\xi)W(\xi) = \text{constant}$. On differentiation with respect to x , we get

$$y'(x) = \frac{1}{A} \left[\int_a^x y_2'(x)y_1(\xi)f(\xi)d\xi + \int_x^b y_1'(x)y_2(\xi)f(\xi)d\xi \right] \quad (9)$$

and

$$y''(x) = \frac{f(x) \cdot W(x)}{A} + \frac{1}{A} \left[\int_a^x y_2''(x)y_1(\xi)f(\xi)d\xi + \int_x^b y_1''(x)y_2(\xi)f(\xi)d\xi \right]$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

Similarly you can use equation number 8 and put x equal to a this term integral will vanish and here it is a to b y_1 x you can take it out and y_1 a basically will be taken out and a to b y_2 ξ f of ξ d ξ .

(Refer Slide Time: 13:22)

If we form the combination $L(y) \equiv p(x)y''(x) + p'(x)y'(x) + q(x)y(x)$ (1), we obtain

$$Ly(x) = \frac{1}{A}[p(x) \cdot f(x) \cdot W(x)] + \frac{1}{A} \left[\int_a^x Ly_2(x)y_1(\xi)f(\xi)d\xi + \int_x^b Ly_1(x)y_2(\xi)f(\xi)d\xi \right] = f(x).$$

Now, we show that $y(x)$ satisfies the boundary conditions (2).
From equation (8) and (9), we obtain

$$y(a) = \frac{1}{A}y_1(a) \int_a^b y_2(\xi)f(\xi)d\xi,$$

$$y'(a) = \frac{1}{A}y_1'(a) \int_a^b y_2(\xi)f(\xi)d\xi,$$

It follows that y satisfies the same homogeneous conditions at $x = a$ as the function y_1 . Similarly, we can find $y(b)$ and $y'(b)$ and show that the boundary conditions (2) are satisfied.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

So it means we are getting this small a is equal to this and y dash a , so basically y at whatever condition y_1 at a satisfy the homogeneous condition y_1 at a satisfy the same boundary condition will be satisfied by this function y of a .

So this follows that y satisfies the same homogeneous condition at x equal to a as the function y_1 , similarly we can do the things for point x equal to b .

(Refer Slide Time: 13:53)

Conversely, the differential equation (1) along with the associated boundary conditions (2) can be shown to imply the relation (5). For this, we have

$$\int_a^b G(x, \xi)f(x)dx = \int_a^\xi G_1(x, \xi)Ly(x)dx + \int_\xi^b G_2(x, \xi)Ly(x)dx$$

Using Green's formula (7), we have

$$\int_a^\xi G_1(x, \xi)Ly(x)dx = p(\xi) \left\{ G_1(\xi, \xi)y'(\xi) - y(\xi) \left[\frac{\partial G_1(x, \xi)}{\partial x} \right]_{x=\xi} \right\} \quad (10)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

$$G(x, \xi) f(x) = \int_a^b G(x, \xi) f(x) dx$$

$$\int_a^b G(x, \xi) f(x) dx = \int_a^b G(x, \xi) y(x) dx$$

So now looking at the converse part we want to show that this differential equation 1 along with the associated boundary condition will give you the expression $y(x)$ equal to $\int_a^b G(x, \xi) f(\xi) d\xi$ for that we consider simply L if you look at here $f(x)$ equal to $Ly(x)$, right? And then what we do? We simply multiply by G of x, ξ here as $G(x, \xi)$ and then integrate between a to b so $\int_a^b G(x, \xi) f(x) dx$ is equal to $\int_a^b G(x, \xi) y(x) dx$.

So it means that we are getting this expression that $\int_a^b G(x, \xi) f(x) dx$, now here we again truncate this interval a to b into a to ξ and ξ to b and between a to ξ this G is given by let me go to this between a to ξ your G is nothing but $G_1(x, \xi)$. Similarly between ξ to b $G(x, \xi)$ is given as $G_2(x, \xi)$ so using this expression 6 we can write it $\int_a^b G(x, \xi) f(x) dx$ as sum of these two integral. Now with the now we want to show that this is nothing but your $y(x)$ here.

So for that we use (15:31) Green's formula between a to ξ , so $\int_a^{\xi} G_1(x, \xi) Ly(x) dx$ if you use this it is nothing but $p(x) G_1(x, \xi) y(x) - \int_a^{\xi} p(x) y'(x) dx$ is outside the entire bracket and this thing. So we are just using the Green's formula for v equal to $G_1(x, \xi)$ and u equal to y .

(Refer Slide Time: 16:01)

Similarly, we have

$$\int_{\xi}^b G_2(x, \xi) Ly(x) dx = -p(\xi) \left\{ G_2(\xi, \xi) y'(\xi) - y(\xi) \left[\frac{\partial G_2(x, \xi)}{\partial x} \right]_{x=\xi} \right\} \quad (11)$$

$$\int_a^b G(x, \xi) f(x) dx = p(\xi) \left\{ G_1(\xi, \xi) y'(\xi) - y(\xi) \left[\frac{\partial G_1(x, \xi)}{\partial x} \right]_{x=\xi} \right\} - p(\xi) \left\{ G_2(\xi, \xi) y'(\xi) - y(\xi) \left[\frac{\partial G_2(x, \xi)}{\partial x} \right]_{x=\xi} \right\}$$

Using the continuity, jump property of the Green's function and the fact that $G(x, \xi) = G(\xi, x)$, we get

$$\int_a^b G(x, \xi) f(\xi) d\xi = y(x).$$

IT BOBASTEE NPTEL ONLINE CERTIFICATION COURSE 8

So the same formula we can apply for the second one for ξ to b $G_2(x, \xi) Ly(x) dx$. So here this will be given like this, so using Green's formula we can write it like this, if we sum these two if we use this expression given in 11 and the expression given in 10 and put it here then we can write $\int_a^b G(x, \xi) f(x) dx$ as this quantity. Now if you look at here this first term $G_1(\xi, \xi) y'(\xi) - y(\xi) \left[\frac{\partial G_1(x, \xi)}{\partial x} \right]_{x=\xi}$ and here $G_2(\xi, \xi) y'(\xi) - y(\xi) \left[\frac{\partial G_2(x, \xi)}{\partial x} \right]_{x=\xi}$.

So here since we already know that function $G(x, \xi)$ is continuous at x equal to ξ so these two will simply equal and since it is plus sign here minus sign so these two will cancel here. Now again using the jump condition for Green function $G(x, \xi)$ we can say that $\int_a^b G_2(x, \xi) f(x) dx - \int_a^b G_1(x, \xi) f(x) dx$ is going to give you 1 upon $p(x)$ here it is x equal to ξ , right? So when you take this this will be cancel out and what you will get is your y of ξ here.

(Refer Slide Time: 17:17)

$$G_1(x, \xi) f(x) = \psi(x)$$

$$\int_a^b G_1(x, \xi) f(x) dx = \int_a^b G_1(x, \xi) \psi(x) dx$$

$$\int_a^b G_1(x, \xi) f(x) dx = p(\xi) \left[\frac{G_1(x, \xi)}{x} \psi(x) - \psi(x) \frac{\partial G_1(x, \xi)}{\partial x} \right]_{x=\xi}$$

$$- p(\xi) \left[\frac{G_2(x, \xi)}{x} \psi(x) - \psi(x) \frac{\partial G_2(x, \xi)}{\partial x} \right]_{x=\xi}$$

$$\psi(\xi) = \int_a^b G_1(x, \xi) f(x) dx = p(\xi) \left[\frac{\partial G_2}{\partial x} - \frac{\partial G_1}{\partial x} \right]_{x=\xi} \psi(\xi)$$

$$\psi(\xi) = \int_a^b G_1(t, \xi) f(t) dt = \psi(\xi)$$

$$\psi(x) = \int_a^b G_1(t, x) f(t) dt$$

$$\psi(x) = \int_a^b G_2(x, t) f(t) dt, \quad G_1(x, t) = G_2(t, x)$$

$$\psi(\xi) = \int_a^b G_1(x, \xi) f(x) dx$$

$$\psi(\xi) = \int_a^b G_1(t, \xi) f(t) dt$$

So what you will get here let me write it here you will get a to b G x, xi f of x dx here I am writing here p of xi and within bracket I am writing here G 1 xi, xi and y dash xi minus y xi G 1 with respect to x here so deba G 1 by deba x and x, xi and it is evaluated at x equal to xi here minus p of xi and G 2 xi, xi y dash xi minus y xi deba G 2 deba x evaluated at x equal to xi. Now since G is spontaneous so this will be canceled out here and using the jump condition it is p of xi and here it is written as deba G 2 deba x at x equal to xi minus deba G 1 deba x at x equal to xi and this y xi is also there so I am taking y xi out because it is common here.

So this is basically 1 upon p xi so I will get y of xi here. So y of xi is given by this formula, now what we try to do here we simply write y xi equal to a to b G x, xi f of x d of x so it means I can write y of say I can write down the same thing as a to b and I can write it here say I can write x as some t so I can write it t xi and f of t d of t. So I can write this as y xi, then I can change xi by x and I can write it here y of x is equal to a to b G of t x f of t dt.

Now we already know that by looking at the structure of G t, x G t, x as same as G x, t so I can write it here a to b G of x, t f of t dt so that is your y of x. So here we are using this fact that G x, t is equal to G t, x. So this says that we have that y, x is defined by this formula if we take our differential equation Ly equal to f and use the property of Green's function then it will also satisfy this expression that is given as y of x equal to a to b G x, xi f of xi d xi.

So that shows that if we know Green function for homogeneous boundary value problem then with the help of this we can actually solve the non-homogeneous boundary value problem.

(Refer Slide Time: 20:53)

Example 1.
Using Green's function, solve the B.V.P.

$$y''(x) - y(x) = x, \quad (12)$$

$$y(0) = y(1) = 0. \quad (13)$$

Solution:
The general solution of the corresponding homogeneous B.V.P. is

$$y(x) = Ae^x + Be^{-x} \quad (14)$$

The B.C. (13) are satisfied iff $A = B = 0$, i.e. $y(x) \equiv 0$. Thus Green's function exists.

NPTEL ONLINE CERTIFICATION COURSE 9

Now let us look at the example based on this so using Green's function solve this non-homogeneous boundary condition so we here we have y double dash x minus y x equal to x boundary conditions are defined at y 0 equal to y 1 equal to 0.

So if you look at this is the operator let us define this as a operator and we can write down the general solution like this and if you use the boundary condition here y 0 equal to y 1 equal to 0

then we can get your both the condition both the constants a and b equal to 0 it means that we have only (0)(21:21) solution. So it means that we can now construct our Green function with the help of this general solution.

(Refer Slide Time: 21:39)

So the Green's function for homogeneous B.V.P. is:

$$G(x, \xi) = \begin{cases} \frac{\sinh x \sinh (\xi-1)}{\sinh 1}, & \text{for } 0 \leq x \leq \xi \\ \frac{\sinh \xi \sinh (x-1)}{\sinh 1}, & \text{for } \xi \leq x \leq 1. \end{cases} \quad (15)$$

So the solution of the B.V.P. is:

$$y(x) = \int_0^1 G(x, \xi) \xi d\xi.$$

On splitting the interval of integration into two parts, we obtain

$$y(x) = \int_0^x \frac{\xi \sinh \xi \sinh (x-1)}{\sinh 1} d\xi + \int_x^1 \frac{\xi \sinh x \sinh (\xi-1)}{\sinh 1} d\xi. \quad (16)$$

10

So for that using the method we have already discussed for construction of Green function for homogeneous boundary value problem we can construct our Green function for this homogeneous boundary value problem and it is given by this $G(x, \xi)$ equal to $\frac{\sinh x \sinh (\xi-1)}{\sinh 1}$ in this interval and similarly we can define for in this interval.

So our solution by the previous I can write $y(x) = \int_0^1 G(x, \xi) \xi dx$ here if you look at your $f(x)$ is nothing but x here so $f(\xi)$ is going to be ξ here. So now putting the values $G(x, \xi)$ here which we have already calculated we can write down like this \int_0^x and \int_x^1 like this. Now if here everything you can calculate basically you can take out this $\frac{\sinh x \sinh (\xi-1)}{\sinh 1}$ upon $\sinh 1$ and in this interval you can take $\frac{\sinh \xi \sinh (x-1)}{\sinh 1}$ out.

(Refer Slide Time: 22:28)

Solving (16) and using the results

$$\int_0^x \xi \sinh \xi d\xi = x \cosh x - \sinh x,$$
$$\int_x^1 \xi \sinh(\xi - 1) d\xi = 1 - x \cosh(x - 1) + \sinh(x - 1),$$

we obtain

$$y(x) = \frac{\sinh x}{\sinh 1} - x.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

And these are simple integral you can find out by integration by part and you can say that this value is equal to this and this integral x to 1 ξ sin hyperbolic ξ minus 1 $d\xi$ is equal to this quantity and if we use this these two integral and the previous expression for y of x you can simplify this expression and you can say that the solution of this non-homogeneous boundary value problem is given by y of x is equal to sin hyperbolic x divided by sin hyperbolic 1 minus x you can actually verify this also.

(Refer Slide Time: 23:05)

Result

Consider the BVP

$$L[y] + \phi(x) = 0, \quad (17)$$
$$V_k(y) = 0, \quad k = 1, 2, \dots, n \quad (18)$$

Here $\phi(x)$ is not given a direct function of x . So $\phi(x)$ can be considered of the form $\phi(x) = f(x, y(x))$ then

$$y(x) = \int_a^b G(x, \xi) f(\xi, y(\xi)) d\xi.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So now let us look at the next result which says that if this function ϕ of x is not a direct of x maybe it means that it is also involving the unknown function y of x then are you can say that ϕ of x is written as f of x y of x then the solution we can write it y of x equal to a to b G x, ξ f of ξ y of ξ $d \xi$. So basically in this case this is not a solution y of x which is given here but the solution y x is given in terms of integral equation or I can say that this differential equation along with this boundary condition is equivalent to the integral equation given here and this is a ((23:45) integral equation given here.

So it means that in this case when ϕ of x is not a function of x only it is involving y of x then this differential equation is converted into integral equation.

(Refer Slide Time: 24:00)

Example 2:
Reduce the following non linear B.V.P. into an integral equation.

$$y'' = f(x, y(x)), \quad (19)$$

$$y(0) = y(1) = 0. \quad (20)$$

Constructing Green's function for the corresponding homogeneous B.V.P., we get

$$G(x, \xi) = \begin{cases} (\xi - 1)x, & \text{for } 0 \leq x \leq \xi; \\ (x - 1)\xi, & \text{for } \xi \leq x \leq 1. \end{cases} \quad (21)$$

Thus solution of given non linear B.V.P. is given by:

$$y(x) = \int_0^1 G(x, \xi) f(\xi, y(\xi)) d\xi.$$

BT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

So just look at one example here take very simple problem Ly is y double dash fx y y 0 equal to y 1 equal to 0 if you remember we have already constructed Green function for this problem homogeneous problem so for this y dash y double dash equal to 0 with boundary condition y 0 equal to y 1 equal to 0 we have G x, ξ equal to this and with this we can write down y x equal to 0 to 1 G x, ξ now here your ϕ x is fx y fx y x so I can write it y x equal to 0 to 1 G x, ξ f of ξ y of ξ $d \xi$.

So here the solution of this boundary value non-homogeneous boundary value problem given in terms of Fredholm integral equation, so this is another use of Green function.

(Refer Slide Time: 24:47)

Boundary Value Problems Containing a Parameter; Reducing them to Integral Equations

Consider the following B.V.P.

$$L[y] = \lambda y + h(x), \quad (22)$$

$$V_k(y) = 0, \quad k = 1, 2, \dots, n, \quad (23)$$

where

$$L[y] \equiv \rho_0(x)y^{(n)}(x) + \rho_1(x)y^{(n-1)}(x) + \dots + \rho_n(x)y(x)$$

$$V_k(y) \equiv \alpha_k y(a) + \alpha_k^{(1)} y'(a) + \dots + \alpha_k^{(n-1)} y^{(n-1)}(a) \\ + \beta_k y(b) + \beta_k^{(1)} y'(b) + \dots + \beta_k^{(n-1)} y^{(n-1)}(b) \quad (k = 1, 2, \dots, n). \quad (24)$$

V_1, V_2, \dots, V_n are L.I., λ is some numerical parameter and $h(x)$ is a continuous function.

IT BOONIKKEE NPTEL ONLINE CERTIFICATION COURSE 14

Now let us use the same thing but now we have λ parameter involving that Ly is given as $\lambda y + h(x)$ or you can say that your $\phi(x)$ is defined as $h(x) + \lambda y$.

(Refer Slide Time: 25:06)

Handwritten derivations on a whiteboard:

$$\alpha(x) = \int_a^b g_1(t, x) f(t) dt$$

$$\alpha(x) = \int_a^b g_2(x, t) f(t) dt, \quad g_1(x, t) = g_2(t, x)$$

$$\phi(x) = f(x) \alpha(x) = \lambda y + h(x)$$

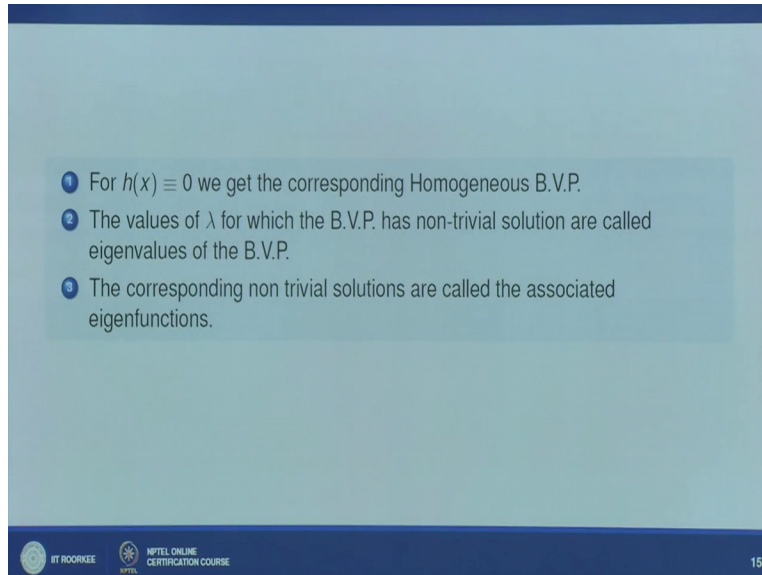

$$\xi(x) = \int_a^b g_1(x, \xi) f(x) dx$$

$$= \int_a^b g_1(t, \xi) f(t) dt$$

So here we have defined $\phi(x)$ equal to $f(x) \alpha(x)$ and we can define this as $\lambda y + h(x)$.

So we can use the result which we have already described and we can say that this problem along with boundary condition here Ly you can take it like this any linear operator (L) (25:28) linear operator we have taken here and boundary condition this.

(Refer Slide Time: 25:33)

Then this also can be converted into integral equation. So here if we take h of x equal to 0 we have a homogeneous boundary value problem and the values for which the values of λ for which we are getting a non-trivial non zero solution we call those values of λ as eigen values of the boundary value problem and the corresponding non-trivial solution we call this as associated eigen functions.

For example, we can have this particular result that if we have Ly equal to 0 and $V_k y$ equal to 0 and for this if we have constructed our Green function this then the previous problem this boundary value problem Ly equal to λy plus $h(x)$ with boundary condition this the solution of that boundary value problem is given in terms of integral equation this Fredholm integral equation where f of x you can define as a to b $G(x, \xi) h(\xi) d\xi$.

(Refer Slide Time: 26:42)

Example
Reduce the following B.V.P.

$$y'' + \lambda y = x \quad (28)$$
$$y(0) = y(\pi/2) = 0 \quad (29)$$

into an integral equation.

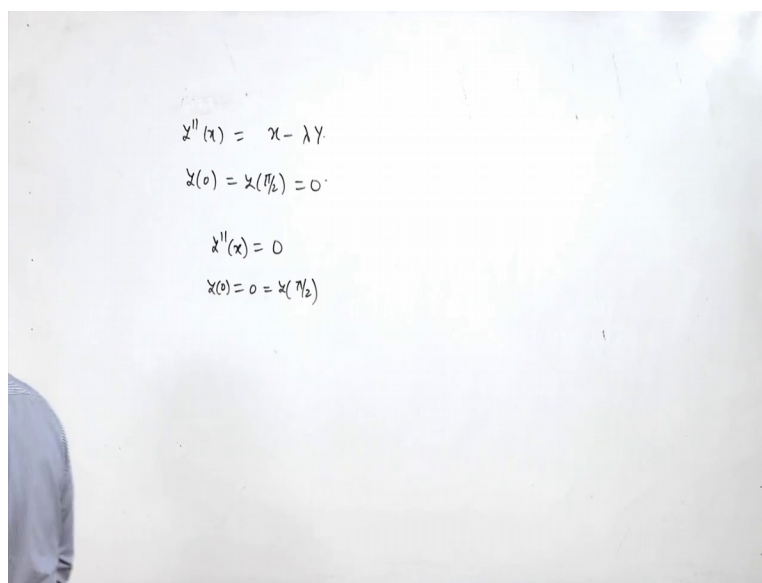

Solution
Since x and $(x - \pi/2)$ are L.I. solutions of the corresponding homogeneous B.V.P. The associated Green's function is:

$$G(x, \xi) = \begin{cases} \frac{y_1(x)y_2(\xi)}{W(\xi)}, & 0 \leq x \leq \xi \\ \frac{y_1(\xi)y_2(x)}{W(\xi)}, & \xi \leq x \leq \pi/2. \end{cases} \quad (30)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 17

So for this let us consider a simple example, so here we have $y'' + \lambda y = x$ so here hx is equal to x here with the boundary condition $y(0) = y(\pi/2) = 0$ and we try to use Green function to convert this differential equation along with boundary condition into a Fredholm integral equation. So for this particular problem $y'' = 0$ we have so we just look at this problem as this.

(Refer Slide Time: 27:22)

So here I will write it here $y'' = x$ I can write it $x - \lambda y$ or you can write it like this and we have $y(0) = y(\pi/2) = 0$.

So what we try to do is we have a corresponding homogeneous condition homogeneous boundary value problem $y'' = 0$, sorry $y'' = x$ equal to 0 with the condition $y(0) = 0$ equal to $y(\pi/2)$ and here we can construct our Green function which is given here as if you remember we have formula for Green function like this. Now here coefficient of y'' is simple 1 so I have not written coefficient of y'' so it is given by this.

Now $y_1(x)$ $y_2(x)$ you can find out as x , x is the solution of $y'' = 0$ which satisfy the boundary condition given at $x = 0$ that is $y(0) = 0$. Similarly, $x - \pi/2$ is a solution of $y'' = 0$ which satisfy the boundary condition given at the end $x = \pi/2$. So we can say that $y_1(x)$ is equal to x and $y_2(x)$ is equal to $x - \pi/2$.

(Refer Slide Time: 28:34)

where $W(\xi) = \pi/2$.

Thus $G(x, \xi) = \begin{cases} (\frac{2}{\pi}\xi - 1)x, & 0 \leq x \leq \xi; \\ (\frac{2}{\pi}x - 1)\xi, & \xi \leq x \leq \pi/2. \end{cases} \quad (31)$

Now making $G(x, \xi)$ as the kernel of the integral equation:

$$y(x) = f(x) - \lambda \int_0^{\pi/2} G(x, \xi)y(\xi)d\xi, \quad (32)$$

where

$$f(x) = \int_0^{\pi/2} G(x, \xi)\xi d\xi$$

BY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 18

So with the help of this and the formula 30 we can write down the expression for $G(x, \xi)$ here.

Now here (())(28:40) we can calculate easily and we can see that it is nothing but $\pi/2$, so with the help of this we have $G(x, \xi)$ like this.

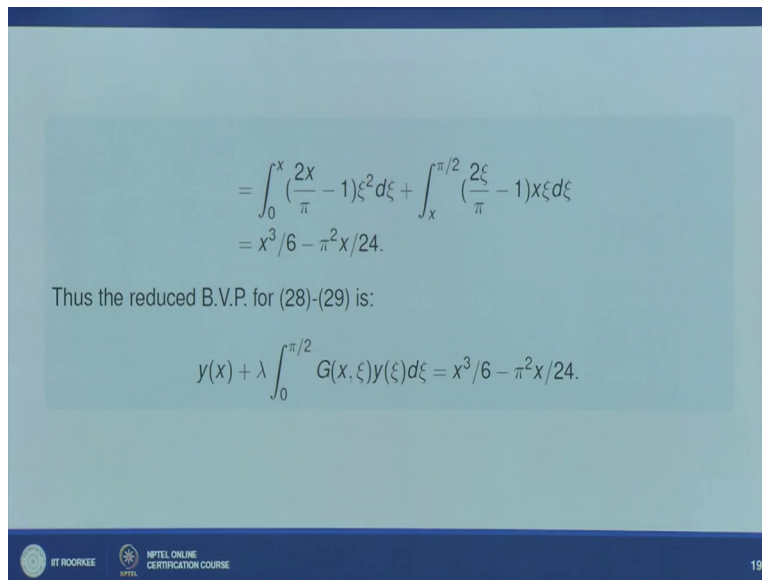

(Refer Slide Time: 28:52)

$$\begin{aligned}
 y''(x) &= x - \lambda y \\
 y(0) &= y(\pi/2) = 0 \\
 y''(x) &= 0 \\
 y(0) &= 0 = y(\pi/2) \\
 y(x) &= \int_0^{\pi/2} G(x, \xi) [x - \lambda y(\xi)] d\xi \\
 y(x) &= -\lambda \int_0^{\pi/2} G(x, \xi) y(\xi) d\xi + \int_0^{\pi/2} \xi G(x, \xi) d\xi
 \end{aligned}$$

Now it means that you can write it here y of x equal to now this is between 0 to $\pi/2$ $G(x, \xi)$, ξ and here we have x minus λy we can say now this is what this is f of ξ here so f of ξ here basically what it will be ξ minus λy of ξ d of ξ . So if you simplify you will get λ 0 to $\pi/2$ $G(x, \xi)$, ξ y of ξ d of ξ plus 0 to $\pi/2$ and it is ξ G of x , ξ d of ξ here so that is y of x .

And this once we know G of x , ξ you can actually calculate this we have calculated here and we can write it this quantity as sum f of x and we can say our solution is given as y of x equal to f minus, okay I have missed here minus 1 minus I have missed here, yeah minus this is minus which I have missed here so it is placed here.

(Refer Slide Time: 30:14)

The slide contains the following mathematical derivations and text:

$$= \int_0^x \left(\frac{2x}{\pi} - 1\right) \xi^2 d\xi + \int_x^{\pi/2} \left(\frac{2\xi}{\pi} - 1\right) x \xi d\xi$$
$$= x^3/6 - \pi^2 x/24.$$

Thus the reduced B.V.P. for (28)-(29) is:

$$y(x) + \lambda \int_0^{\pi/2} G(x, \xi) y(\xi) d\xi = x^3/6 - \pi^2 x/24.$$

The footer of the slide includes the logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, along with the page number 19.

So here $f(x)$ you can calculate as $\int_0^{\pi} G(x, \xi) d\xi$. So $G(x, \xi)$ is already given here so let us calculate this f of x here so between 0 to x ξ is we have between, sorry between ξ between 0 to x means ξ less than x we have what ξ less than x we have this $2x/\pi - 1$ into ξ .

So use this here we have the expression and between ξ greater than x we can use this thing $2\xi/\pi - 1$ so using this we can find out the value of this 2 integral and it is coming out to be $x^3/6 - \pi^2 x/24$ it is not very difficult thing it is simple integration and with this value you have the solution of this problem $y(x) = \lambda \int_0^{\pi/2} G(x, \xi) y(\xi) d\xi$ and this is your f of x given here.

(Refer Slide Time: 31:31)

Dr. D.N. Pandey
Department of Mathematics, IIT Roorkee

So it means that with the help of Green function you can actually show the equivalence of a non-homogeneous boundary value problem of this particular type into Fredholm integral equation that what happened I hope we have already discussed that we have Ly equal to f of x with the boundary condition that $V_k(y) = 0$ and we have discussed this but suppose in that suppose these boundary conditions are not homogeneous it is basically non-homogeneous then how we can write it.

So we can say that suppose your these are not homogeneous suppose we have these are some α_k some values which is non-zero, then how we can handle here? So this we can handle in

this two way so what we try to do is we construct Green function for this Ly equal to 0 with the condition that $V_k y$ is simply 0, right? And we say that for this we have a Green function G of x, ξ and we can find out the solution of the corresponding non-homogeneous boundary value problem as y of x equal to simple a to b and assuming that x is lying between a to b x is in between a to b .

So here it is a to b G of x, ξ f of ξ d of ξ , so if it is not αk or all 0 your solution is given in this particular form, but suppose αk is simply non-zero then what to do then what we try to do we simply convert this thing into two problem so let me write it here it is f of x here okay, so this is the solution of what? This is the solution of Ly equal to f with $V_k y$ equal to 0. Now what we try to do let us look at this particular problem we take Ly equal to 0 and $V_k y$ equal to say αk and we can find out the solution here.

And suppose the solution you can find out and say that f of x , then the solution of the original problem is solution of this problem is basically your y equal to solution of this problem call it y_1 and solution so it is given as y_1 plus f of x here. So solution of the non-homogeneous problem with non-homogeneous boundary condition can also be given with the help of this that solution of homogeneous problem you find out like this and the solution of homogeneous problem but non-homogeneous condition and say that solution is given by y equal to fx so we call it y_2 equal to fx .

And solution of this non-homogeneous solution of this original problem I can give it like this y equal to y_1 plus y_2 where y_1 is given by this and y_2 is given by this. So this is y equal to a to b G x, ξ f of ξ d of ξ plus f of x here you can verify this by simply operating your L on this, okay. So here we are using principle of super position to truncate this problem into 2 part one with non-homogeneous equation with homogeneous boundary condition and a homogeneous differential equation with non-homogeneous boundary condition and you can easily solve this problem and your solution on this problem is given by this you can do this problem maybe we can discuss some problem in next assignment here.

So now here we close this lecture here and we will again discuss some more problem, okay thank you very much.
