Equations with Convolution Type Kernels I

Hello friends I welcome you to my lecture on equations with convolution type kernels. There will be two lectures on this topic. So this is first of these two lectures. Let us consider the linear integral equations with convolution type kernels. Let us take two functions $\phi_1(x)$ and $\phi_2(x)$ which are defined for x greater than or equal to 0 and are continuous then the convolution of these two functions $\phi_1(x)$ and $\phi_2(x)$ is defined by a function $\phi_3(x)$ equal to integral from 0 to x , $\phi_1(x-t)$ into $\phi_2(t) dt$.

It turns out that the function $\phi_3(x)$ is also continuous for x greater than or equal to 0. Let us say that the Laplace transforms of the functions $\phi_1(x)$ and $\phi_2(x)$ be denoted by $\phi_1(s)$ and $\phi_2(s)$ respectively so that $L\phi_1(x)$ is equal to $\phi_1(s)$ and $L\phi_2(x)$ equal to $\phi_2(s)$.

(Refer Slide Time: 01:20)

Equations with Convolution type kernels

Let $\phi_1(x)$ and $\phi_2(x)$ be two continuous functions defined for $x \geq 0$. Then the convolution of these two functions is defined as

$$\phi_3(x) = \int_0^x \phi_1(x-t)\phi_2(t)dt.$$

This function is also continuous for $x \geq 0$.

Let the Laplace transforms of $\phi_1(x)$ and $\phi_2(x)$ be denoted by

$$L(\phi_1(x)) = \Phi_1(s) \quad \text{and} \quad L(\phi_2(x)) = \Phi_2(s),$$

III ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

Then by the (convolu) convolution theorem for the Laplace transforms we have Laplace transform of $\phi_3(x)$. So Laplace transform of $\phi_3(x)$ is the product of the Laplace transforms of $\phi_1(x)$ and $\phi_2(x)$ which is equal to $\phi_1(s)$ into $\phi_2(s)$.

(Refer Slide Time: 02:14)

Now let us consider the Volterra type integral equation of the second kind, $y(x)$ equal to $f(x)$ plus integral 0 to x , $K(x-t)y(t)dt$. So here $f(x)$ is a known function, $K(x-t)$ is also known, this kernel of the integral equation K is solely dependent on the difference $x-t$ of the arguments t and x and then you have $y(t)$, the unknown function.

So let us see how we can solve such an integral equation where the kernel $K(x-t)$ is solely dependent on the difference of the arguments x and t that is $x-t$ is called an integral equation with convolution type kernels.

(Refer Slide Time: 02:58)

then by the convolution theorem for Laplace transforms, we have

$$L(\phi_3(x)) = L(\phi_1(x))L(\phi_2(x)) = \Phi_1(s)\Phi_2(s).$$

Now, consider the Volterra type integral equation of the second kind

$$y(x) = f(x) + \int_0^x K(x-t)y(t)dt, \quad \dots(1)$$

where the kernel $K(x, t)$ is solely dependent on the difference $x-t$.
Such an integral equation is called an integral equation with convolution type kernels.

So what we will do is, okay. So let $f(x)$ and $K(x-t)$ be sufficiently smooth functions such that as x goes to infinity, $|f(x)|$ is less than or equal to $M e^{-\alpha x}$, $\alpha > 0$.

of $K(x, t)$ is less than or equal to $M_2 e^{-\alpha_2 x}$. That means $f(x)$ and $K(x, t)$ are both of exponential order. Then using the method of successive approximations it turns out that $|y(x)|$ is less than or equal to $M_3 e^{-\alpha_3 x}$.

Now consequently the Laplace transforms of $f(x)$, $K(x, t)$ and $y(x)$ exist. Let us assume that Laplace transform of $f(x)$ is $F(s)$ and Laplace transform of $K(x, t)$ is $\tilde{K}(s)$ and Laplace transform of $y(x)$ is equal to $Y(s)$. Here remember that $K(x, t)$ is kernel of the type $x - t$, that means $K(x, t)$ is a function of $x - t$.

(Refer Slide Time: 04:04)

Let $f(x)$ and $K(x,t)$ be sufficiently smooth functions such that as $x \rightarrow \infty$,

$$|f(x)| \leq M_1 e^{-\alpha_1 x}, |K(x,t)| \leq M_2 e^{-\alpha_2 x}$$

then using the method of successive approximation, we get

$$|y(x)| \leq M_3 e^{-\alpha_3 x}.$$

Consequently, the Laplace transform of $f(x)$, $K(x,t)$ and $y(x)$ exist.

Let

$$L(f(x)) = F(s), \quad L(K(x,t)) = \tilde{K}(s) \quad \text{and} \quad L(y(x)) = Y(s).$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So what we will do is let us take the Laplace transform of both sides of the equation 1. When you take the Laplace transform of this equation 1, Laplace transform of $y(x)$ will be $Y(s)$ which will be equal to Laplace transform of $f(x)$ which we have assumed as equal to $F(s)$. And then Laplace transform of $\int_0^x K(x-t)y(t) dt$ which by making use of the convolution theorem for Laplace transforms we can write as the product of the Laplace transform of $K(x, t)$ and $y(t)$.

(Refer Slide Time: 04:37)

then by the convolution theorem for Laplace transforms, we have

$$L(\phi_3(x)) = L(\phi_1(x))L(\phi_2(x)) = \Phi_1(s)\Phi_2(s).$$

Now, consider the Volterra type integral equation of the second kind

$$y(x) = f(x) + \int_0^x K(x-t)y(t)dt, \quad \dots(1)$$

where the kernel $K(x, t)$ is solely dependent on the difference $x-t$.
Such an integral equation is called an integral equation with convolution type kernels.

3

So this will be equal to $Y(s)$ equal to $F(s)$ plus Laplace transform of $K(x, t)$ which we have assumed as $\tilde{K}(s)$ into $Y(s)$. Then we can solve this equation for $Y(s)$ and $Y(s)$ will be equal to $F(s)$ over $1 - \tilde{K}(s)$ where we are assuming that $\tilde{K}(s)$ is not equal to 1. So then the solution $y(x)$ of the integral equation (1) is found by taking the inverse Laplace transform of $Y(s)$ that is we get $y(x)$ equal to $L^{-1}(Y(s))$.

(Refer Slide Time: 05:13)

Taking the Laplace transform of both sides of equation (1) and using the convolution theorem, we find

$$Y(s) = F(s) + \tilde{K}(s)Y(s)$$

$$Y(s) = \frac{F(s)}{1 - \tilde{K}(s)}, \quad (\tilde{K}(s) \neq 1).$$

The solution $y(x)$ of the integral equation (1) is then found by taking the inverse Laplace of $Y(s)$ i.e.

$$y(x) = L^{-1}(Y(s)).$$

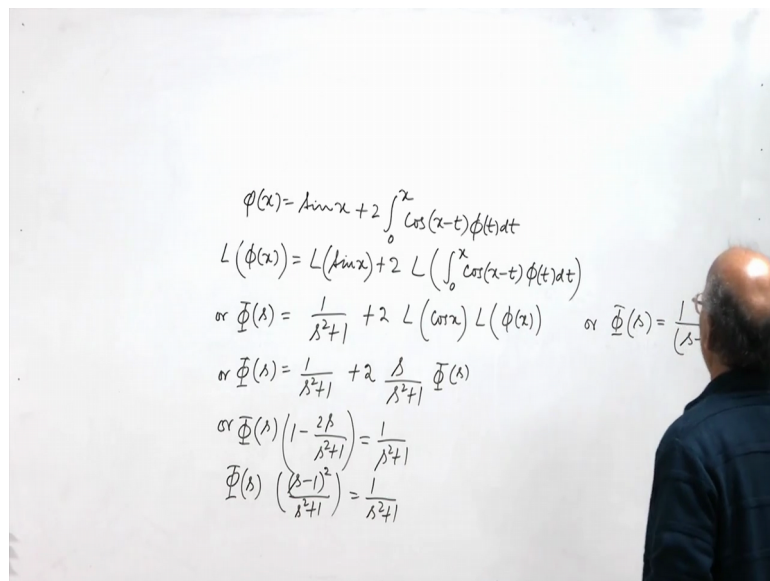

5

Now let us see how we apply this method to solve a integral equation of Volterra type of second kind. So let us consider the integral equation $\phi(x) = \sin x + 2 \int_0^x \cos(x-t)\phi(t)dt$. So let us take the Laplace transform of both sides. So then Laplace transform of both sides when we take we will get Laplace transform of $\phi(x)$ equal to

Laplace transform of $\sin x$ plus 2 times Laplace transform of this convolution of $\cos x$ and $\phi(x)$, so 0 to x $\cos(x-t)$ into $\phi(t) dt$.

Or we can say $\Phi(s)$ is equal to $\frac{1}{s^2+1}$ plus 2 times Laplace transform of $\cos x$ into Laplace transform of $\phi(x)$. Or we can say $\Phi(s)$ equal to $\frac{1}{s^2+1}$ plus $2s$ over s^2+1 into $\Phi(s)$. Let us collect the coefficient of $\Phi(s)$, so $\Phi(s)$ times $1 - 2s$ over s^2+1 equal to $\frac{1}{s^2+1}$. Or we can say $\Phi(s)$ times $s - 1$ whole square divided by s^2+1 is equal to $\frac{1}{s^2+1}$. Or we can say $\Phi(s)$ equal to $\frac{1}{s-1}$ whole square.

(Refer Slide Time: 07:52)

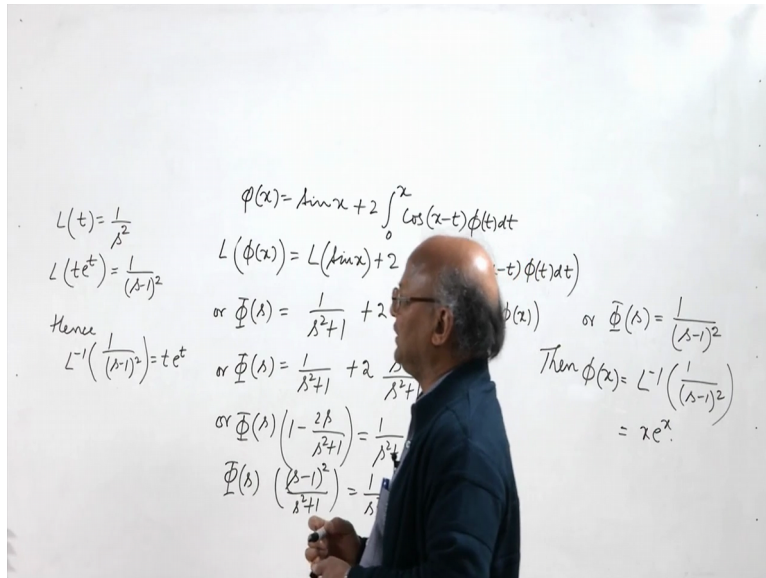

$$\begin{aligned} \phi(x) &= \sin x + 2 \int_0^x \cos(x-t) \phi(t) dt \\ L(\phi(x)) &= L(\sin x) + 2 L\left(\int_0^x \cos(x-t) \phi(t) dt\right) \\ \text{or } \Phi(s) &= \frac{1}{s^2+1} + 2 L(\cos x) L(\phi(x)) \quad \text{or } \Phi(s) = \frac{1}{s-1} \\ \text{or } \Phi(s) &= \frac{1}{s^2+1} + 2 \frac{s}{s^2+1} \Phi(s) \\ \text{or } \Phi(s) \left(1 - \frac{2s}{s^2+1}\right) &= \frac{1}{s^2+1} \\ \Phi(s) \left(\frac{s-1}{s^2+1}\right) &= \frac{1}{s^2+1} \end{aligned}$$

Now then the unknown function $\phi(x)$ is obtained by taking inverse Laplace transform of $\frac{1}{s-1}$ whole square. Now let us recall that Laplace transform of t is equal to $\frac{1}{s^2}$. Laplace transform of t is $\frac{1}{s^2}$ and by the first shifting theorem when you multiply t by e to the power t , s is replaced by $s-1$.

So we get $\frac{1}{s-1}$ whole square. So thus we can say that hence L inverse of $\frac{1}{s-1}$ whole square is equal to $t e$ to the power t . Now here ϕ is a function of x so I can write it as x times e to the power x .

(Refer Slide Time: 08:58)

Thus the solution of the integral equation $\phi(x) = \sin x + 2 \int_0^x \cos(x-t) \phi(t) dt$ will be equal to $x e^x$.

(Refer Slide Time: 09:09)

Example 1: Consider

$$\phi(x) = \sin x + 2 \int_0^x \cos(x-t) \phi(t) dt.$$

Solution : Taking the Laplace transform of both sides, we get

$$\Phi(s) = \frac{1}{s^2+1} + 2 \frac{s}{s^2+1} \Phi(s)$$

$$\Phi(s) = \frac{1}{(s-1)^2}.$$

Taking the inverse Laplace transform, we have

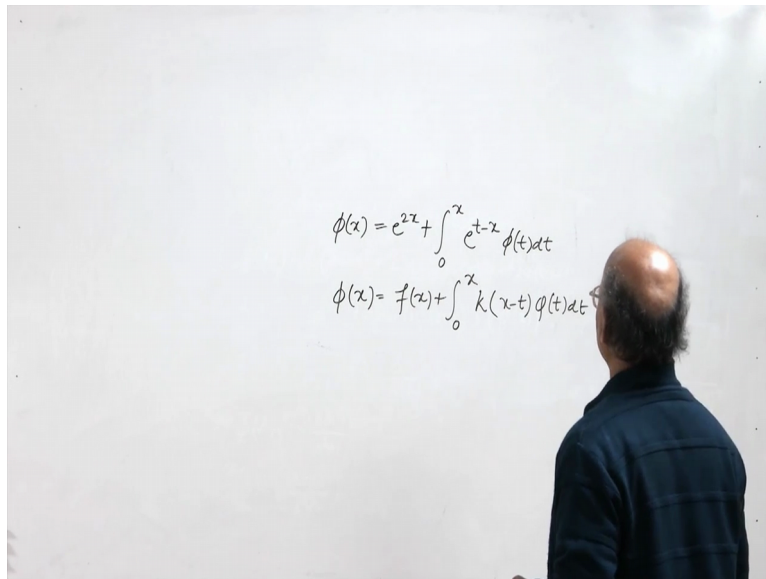

$$\phi(x) = x e^x.$$

6

Now let us take one more example on this. Consider the Volterra integral equation of the second kind $\phi(x) = e^{2x} + \int_0^x e^{t-x} \phi(t) dt$, okay. So we will be solving it by taking the Laplace transform of both sides but here let us (not) notice that when we compare it with the standard Volterra integral equation of second kind with convolution type kernel, here we should be having $\phi(x) = f(x) + \int_0^x K(x-t) \phi(t) dt$.

So instead of $t-x$ we should be having $x-t$.

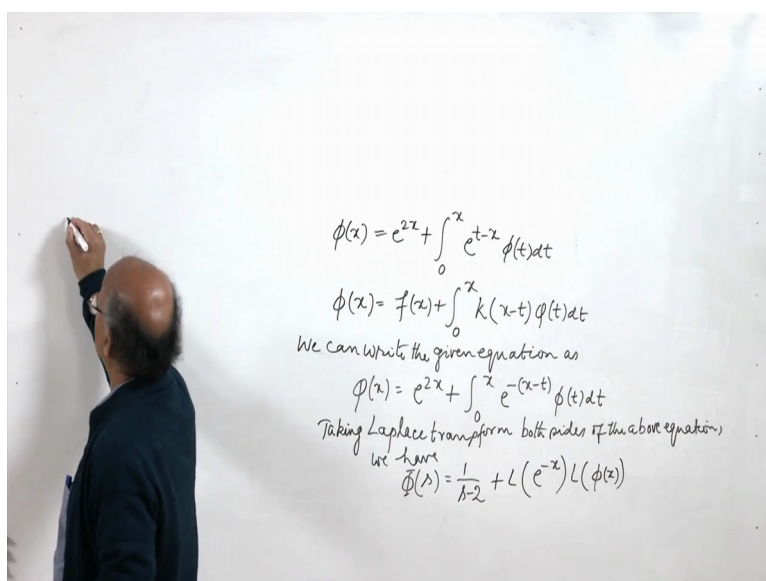

(Refer Slide Time: 10:31)

So what we write is we can write the given equation as $\phi(x)$ equal to e to the power $2x$ plus integral 0 to x , e to the power minus x minus t into $\phi(t) dt$. So $K(x,t)$ is e to the power minus x minus t . Now let us take the Laplace transform of both sides.

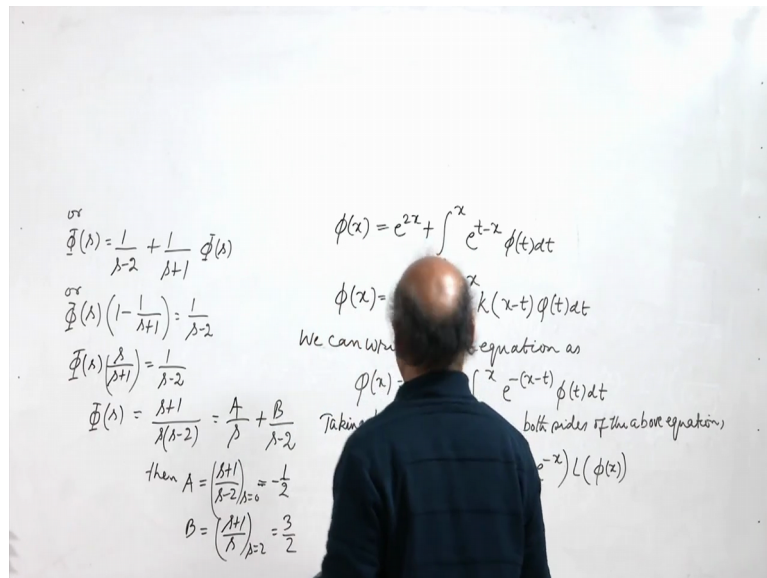

So taking Laplace transform of both sides of the above equation we have $\phi(s)$ is Laplace transform of $\phi(x)$, then Laplace transform of e to the power $2x$ is 1 over s minus 2 plus Laplace transform of the convolution 0 to x , e to the power minus x minus t , $\phi(t) dt$. So this is Laplace transform of e to the power minus x into Laplace transform of $\phi(x)$.

(Refer Slide Time: 12:08)

And so we can write it as $\phi(s) = \frac{1}{s+1} + \frac{1}{s-2}$. So I will have $\frac{1}{s+1}$, $\frac{1}{s-2}$ or $\phi(s) = \frac{1}{s+1} + \frac{1}{s-2}$. We can break it into partial fractions. So A upon $s+1$ plus B upon $s-2$. Then A is given by $\frac{1}{s-2}$ at $s = -1$. So we have $-\frac{1}{3}$. And B is equal to $\frac{1}{s+1}$ at $s = 2$. So it is $\frac{3}{2}$.

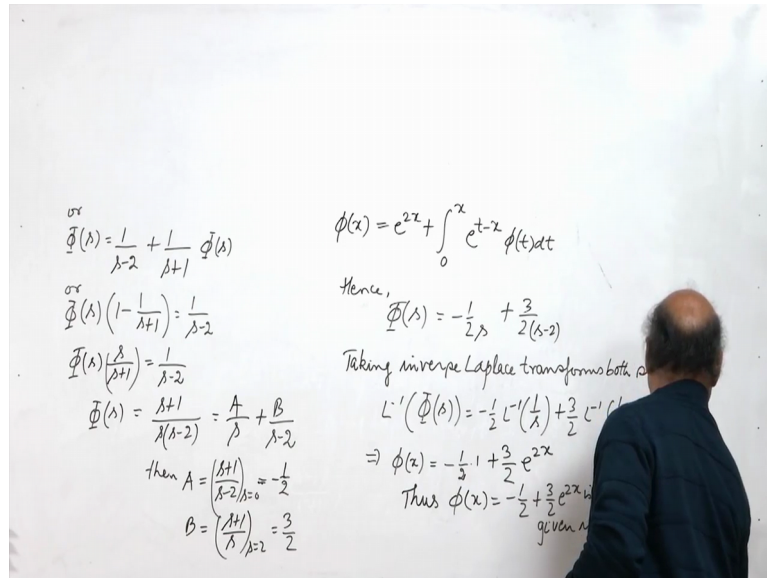

(Refer Slide Time: 13:54)

So thus we get $\phi(s) = \frac{-1}{2(s+1)} + \frac{3}{2(s-2)}$. Now (Lap) taking inverse Laplace transform both sides, $L^{-1} \phi(s) = \frac{-1}{2} L^{-1} \frac{1}{s+1} + \frac{3}{2} L^{-1} \frac{1}{s-2}$ which gives us the solution of the given integral equation.

So $\phi(x) = \frac{-1}{2} e^{-x} + \frac{3}{2} e^{2x}$. This is the solution of the given integral equation.

(Refer Slide Time: 16:16)

Okay now one more problem I have taken here. I can discuss it here, $\phi(x)$ equal to x minus 0 to x , \sin hyperbolic x minus t , $\phi(t) dt$. When we take Laplace transform of both sides Laplace transform of $\phi(x)$ is $\phi(s)$, Laplace transform of x is 1 over s square minus Laplace transform of \sin hyperbolic x . And Laplace transform of \sin hyperbolic x is 1 over s square minus 1 into Laplace transform of $\phi(x)$ which is $\phi(s)$.

So we can collect the coefficients of $\phi(s)$ which is 1 plus 1 over s square minus 1 and then divide by the coefficients of $\phi(s)$. So we get $\phi(s)$ equal to 1 over s square minus 1 over s to the power 4 and then we can take the inverse Laplace transform of this equation. So L inverse of $\phi(s)$ gives us $\phi(x)$ and L inverse of 1 over s square is x , L inverse of 1 over s to the power 4 is x cube by 6 . So the solution of the given Volterra integral equation of convolution type is $\phi(x)$ equal to x minus x cube by 6 .

(Refer Slide Time: 17:34)

Example 3. Consider $\phi(x) = x - \int_0^x \sinh(x-t)\phi(t)dt.$

Solution: Taking the Laplace transform of both sides, we get

$$\Phi(s) = \frac{1}{s^2} - \frac{1}{s^2-1}\Phi(s)$$

$$\Phi(s) = \frac{1}{s^2} - \frac{1}{s^4}.$$

Taking the inverse Laplace transform, we have

$$\phi(x) = x - \frac{x^3}{6}.$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 8

Now there is one more equation, $\phi(x) = 1 - 2x - 4x^2 + \int_0^x (3 + 6(x-t) - 4(x-t)^2)\phi(t)dt.$
 There is a problem which let us do here.

(Refer Slide Time: 17:46)

Example 4: Consider

$$\phi(x) = 1 - 2x - 4x^2 + \int_0^x (3 + 6(x-t) - 4(x-t)^2)\phi(t)dt.$$

Solution: Taking the Laplace transform of both sides, we get

$$\Phi(s) = \frac{s^2 - 2s - 8}{s^3 - 3s^2 - 6s + 8}.$$

Taking the inverse Laplace transform, we have

$$\phi(x) = e^x.$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 9

So $\phi(x)$ is equal to $1 - 2x - 4x^2 + \int_0^x (3 + 6(x-t) - 4(x-t)^2)\phi(t)dt.$ In my lecture on Volterra integral equations of second kind where $K(x,t)$ is of some special forms there we have discussed this problem because the kernel here is a polynomial in t of degree 2.

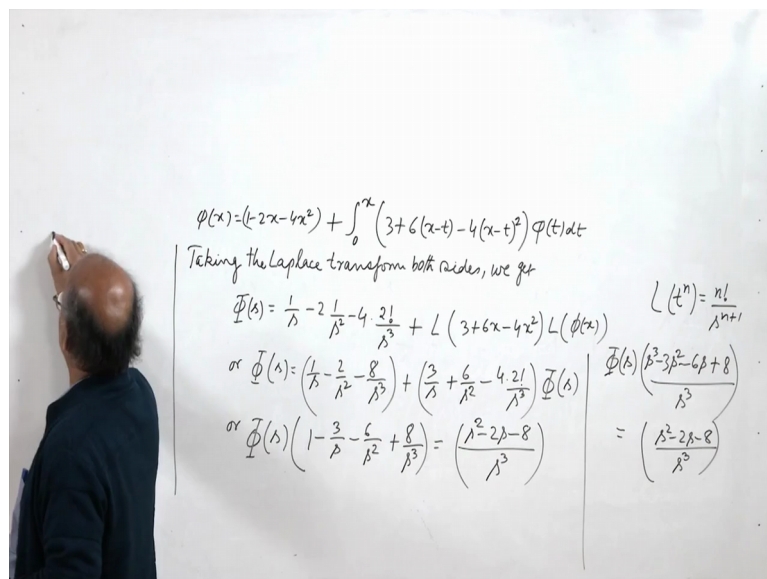

So we can solve it by the method which we discussed there but you will see now that when we solve this by using the Laplace transform, the solution of this integral equation comes very easily. So let us take the Laplace transform of this.

So taking Laplace transform on both sides we get $\Phi(s)$, Laplace transform of 1 which is $\frac{1}{s}$ minus 2 times Laplace transform of x is $\frac{1}{s^2}$ minus 4 times Laplace transform s^2 is Laplace transform of t to the power n is equal to n factorial divided by s to the power n plus 1. So Laplace transform of s^2 is 2 factorial that is 2 factorial divided by s to the power 3 plus Laplace transform of this convolution. So Laplace transform of $3 + 6x - 4x^2$ into Laplace transform of $\phi(x)$.

So what we get is $\Phi(s)$ equal to $\frac{1}{s}$ minus $\frac{2}{s^2}$ minus $\frac{8}{s^3}$ plus Laplace transform of $3 + 6x - 4x^2$ is $\frac{3}{s}$ plus $\frac{6}{s^2}$ minus $\frac{4 \cdot 2!}{s^3}$ into $\Phi(s)$. We can then collect the coefficients of $\Phi(s)$, so what we get is $\frac{1}{s}$ minus $\frac{3}{s}$ minus $\frac{6}{s^2}$ plus $\frac{8}{s^3}$ equal to, $\frac{1}{s}$ minus $\frac{2}{s^2}$ minus $\frac{8}{s^3}$ let us take LCM there.

So we get s^3 and then we get s^2 minus $2s$ minus 8 . So simplifying we get $\Phi(s)$ times s^3 , we have s^3 minus $3s^2$ minus $6s$ plus 8 , this is equal to s^3 minus $2s$ minus 8 divided by s^3 .

(Refer Slide Time: 21:48)

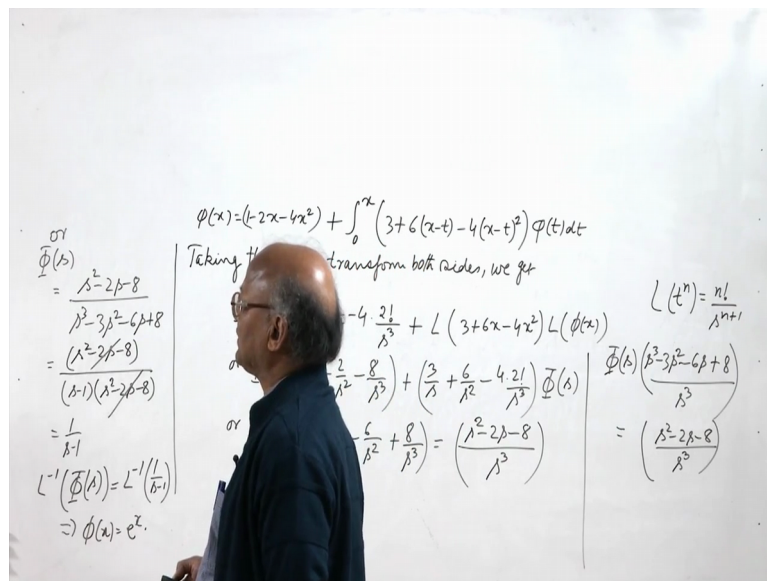

Now so $\Phi(s)$ is equal to s^3 minus $2s$ minus 8 divided by s^3 minus $3s^2$ minus $6s$ plus 8 . Now we can see that the denominator is a polynomial of degree 3 in s and s equal to 1 is a root of this polynomial because when you put s equal to 1 what we have is 1 minus 3 minus 6 plus 8 . So s equal to 1 is a root of this polynomial. So s minus 1 is a factor and when you divide it by s minus 1 what you get is, s^2 minus $2s$ minus 8 . So s^2

minus 2 s minus 8 divided by s minus 1, the denominator can be written as s minus 1 into s square minus 2 s minus 8.

So we can cancel this and we get 1 over s minus 1. Now phi s is equal to 1 over s minus 1, so taking inverse Laplace transform, so L inverse of phi s is equal to L inverse of 1 over s minus 1 which implies phi x equal to e to the power x. So phi x is equal to e to the power x is the solution of the given Volterra integral equation of second kind.

(Refer Slide Time: 23:19)

when we discussed this problem there when K x t is of some particular form, there the solution was quite lengthy but you can see here that by using the Laplace transform we can find the solution of this Volterra integral equation very easily. Now let us consider system of Volterra type integral equations.

A system of Volterra type integral equations can also be (salv) solved by making use of the Laplace transformation. So let us see how we solve the system of Volterra type integral equations of (seco) second kind.

(Refer Slide Time: 23:58)

Solution of a system of Volterra type integral equations:

Let us consider a system of Volterra type integral equations

$$y_i(x) = f_i(x) + \sum_{j=1}^n \int_0^x K_{ij}(x-t)y_j(t)dt, \quad (i=1,2,\dots,n) \quad \dots(2)$$

where $K_{ij}(x)$ and $f_i(x)$ are known continuous functions whose Laplace transforms exist.

Taking the Laplace transform of both sides of (2), we get

$$Y_i(s) = F_i(s) + \sum_{j=1}^n \tilde{K}_{ij}(s)Y_j(s), \quad (i=1,2,\dots,n)$$

Let us consider a system of Volterra type integral equation, $y_i(x)$ equal to $f_i(x)$ plus sigma j equal to 1 to n , integral 0 to x , $K_{ij}(x-t)y_j(t)dt$. So there are n integral equations here and therefore there are n functions to be determined. The unknown functions are $y_i(x)$ where i runs from 1 to n . So there are n integral equations and therefore there are n (indep) unknown functions $y_i(x)$.

And the functions $f_i(x)$ for i equals to 1 to n and the functions $K_{ij}(x)$ are known continuous functions whose Laplace transforms exist. So we are assuming that the Laplace transforms of the kernel and the (func) function for $f_i(x)$ do exist. And then what we do is we take the Laplace transform of both sides of this equation.

When you take Laplace transform of both sides here what you get is (())(25:05) Laplace transform of $y_i(x)$ by capital $Y_i(s)$ and Laplace transform of $f_i(x)$ by capital $F_i(s)$. And then we have sigma j equal to 1 to n . This is convolution of $K_{ij}(x)$ and $y_j(x)$. So product of the Laplace transforms of $K_{ij}(x)$ and $y_j(x)$. So Laplace transform of $K_{ij}(x)$ we are denoting by $\tilde{K}_{ij}(s)$ and Laplace transform of $y_j(x)$ we are denoting by $Y_j(s)$.

(Refer Slide Time: 25:41)

Solution of a system of Volterra type integral equations:

Let us consider a system of Volterra type integral equations

$$y_i(x) = f_i(x) + \sum_{j=1}^n \int_0^x K_{ij}(x-t)y_j(t)dt, \quad (i=1,2,\dots,n) \quad \dots(2)$$

where $K_{ij}(x)$ and $f_i(x)$ are known continuous functions whose Laplace transforms exist.

Taking the Laplace transform of both sides of (2), we get

$$Y_i(s) = F_i(s) + \sum_{j=1}^n \tilde{K}_{ij}(s)Y_j(s), \quad (i=1,2,\dots,n)$$

So here we are denoting Laplace transform of $f_i(x)$ by $F_i(s)$, Laplace transform of $y_i(x)$ by $Y_i(s)$ and Laplace transform of K_{ij} . So this is what we have and then we will have these n equations. So this is a system of linear algebraic equation in $Y_i(s)$.

You can see here this a system of linear algebraic equations in $Y_i(s)$ and we shall solve these linear system and to determine the expressions for this function $Y_i(s)$ and then we will take the inverse Laplace transform of $Y_i(s)$ to get the unknown function $y_i(x)$ for i equal to 1, 2, 3 and so on up to n .

Let us say for example we consider this system of algebraic equations, $\phi_1(x) = 1 - 2 \int_0^x e^{2(x-t)} \phi_1(t) dt + \int_0^x \phi_2(t) dt$. And the second equation is $\phi_2(x) = 4x - \int_0^x \phi_1(t) dt + 4 \int_0^x (x-t) \phi_2(t) dt$.

(Refer Slide Time: 27:11)

This is a system of linear algebraic equations in $Y_i(s)$. It is solved to find $Y_i(s)$ then we take its inverse Laplace transform to obtain the solution $y_i(x)$, $i = 1, 2, 3 \dots, n$ of the original system (2) of integral equations.

Example: Consider the system of algebraic equations

$$\phi_1(x) = 1 - 2 \int_0^x e^{2(x-t)} \phi_1(t) dt + \int_0^x \phi_2(t) dt,$$

$$\phi_2(x) = 4x - \int_0^x \phi_1(t) dt + 4 \int_0^x (x-t) \phi_2(t) dt.$$

Then so we get a system of linear algebraic equations in $Y_i(s)$. There will be n equations in the unknown function $Y_i(s)$. We can determine the unknown functions $Y_i(s)$ from these n equations. And then in order to find the solution of the given system we will then take the inverse Laplace transform of $Y_i(s)$. So taking inverse Laplace transform of $Y_i(s)$ we will determine the unknown function $y_i(x)$ for i equal to 1, 2, 3 and so on up to n which gives us the solution of the original system (2) of integral equations.

We have given an example, consider the system of algebraic equations, $\phi_1(x)$ equal to 1 minus 2 times integral 0 to x , e to the power 2 x minus t , $\phi_1(t) dt$ plus integral 0 to x , $\phi_2(t) dt$ and $\phi_2(x)$ equal to 4 x minus integral 0 to x , $\phi_1(t) dt$ plus 4 times integral 0 to x , x minus t , $\phi_2(t) dt$.

So here there are two unknown functions $\phi_1(x)$ and $\phi_2(x)$. We will be taking the Laplace transform of these two integral equations and then we will get the unknown functions $\phi_1(s)$ and $\phi_2(s)$. The unknown $\phi_1(s)$ and $\phi_2(s)$ will be determined from the two algebraic equations in $\phi_1(s)$ and $\phi_2(s)$ and we shall be taking their inverse Laplace transform to determine the unknown functions $\phi_1(x)$ and $\phi_2(x)$. With this I would like to conclude my lecture. Thank you very much for your attention.
