Second alternative form of Hilbert transform

Rewriting

$$F(\theta) = \frac{1}{2\pi} \int_0^{*\pi} \cot \frac{\theta + \phi}{2} Y(\phi) d\phi + \frac{1}{2\pi} \int_0^{*\pi} \cot \frac{\theta - \phi}{2} Y(\phi) d\phi,$$

as

$$F(\theta) = \frac{1}{2\pi} \int_0^{*\pi} \left\{ 1 + \cot \frac{\theta + \phi}{2} \right\} Y(\phi) d\phi + \frac{1}{2\pi} \int_0^{*\pi} \left\{ 1 + \cot \frac{\theta - \phi}{2} \right\} Y(\phi) d\phi,$$

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

Hello friends I welcome you to my second lecture on Hilbert transforms. We are going to now discuss second alternative form of Hilbert transform pair. let us recall that we had the equation in the first alternative form we had capital F theta written in this form, capital F theta we had written in this form and then we had combined these 2 forms and we got the first alternative form of the Hilbert transform pair by replacing phi by minus phi in the first integral.

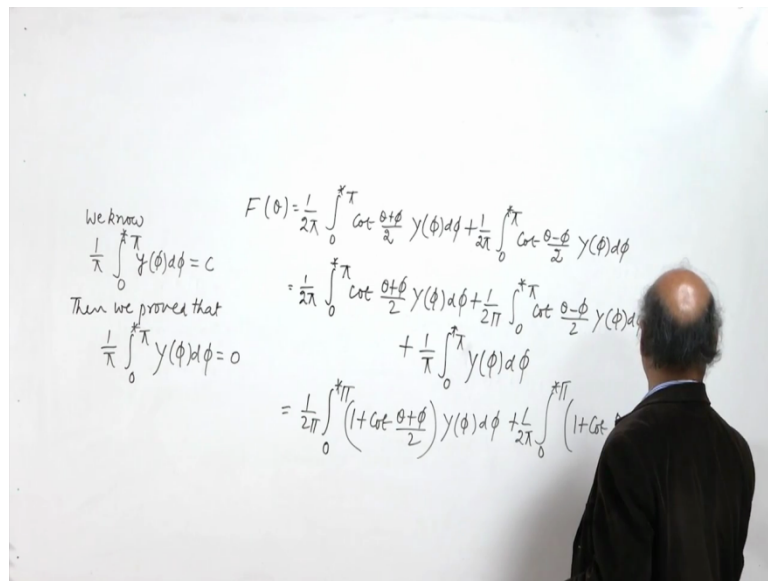

(Refer Slide Time 1:19)

So this was our first integral and this integral now let us see we can write like this, so $F(\theta)$ equal to $\frac{1}{2\pi}$ integral over 0 to π $\cot(\theta + \frac{\phi}{2}) Y(\phi) d\phi$ plus $\frac{1}{2\pi}$ integral over 0 to π $\cot(\theta - \frac{\phi}{2}) Y(\phi) d\phi$. In the previous lecture when we were finding the first alternative form so is while finding the first alternative form of the equation 1 we encountered this equation.

So this equation $F(\theta)$ equal to $\frac{1}{2\pi}$ integral over 0 to π $\cot(\theta + \frac{\phi}{2}) Y(\phi) d\phi$ plus this can be expressed as $\frac{1}{\pi} F(\theta)$ equal to $\frac{1}{2\pi}$ integral over 0 to π $1 + \cot(\theta + \frac{\phi}{2}) Y(\phi) d\phi$ plus $\frac{1}{2\pi}$ integral over 0 to π $1 + \cot(\theta - \frac{\phi}{2}) Y(\phi) d\phi$, how we can do this?

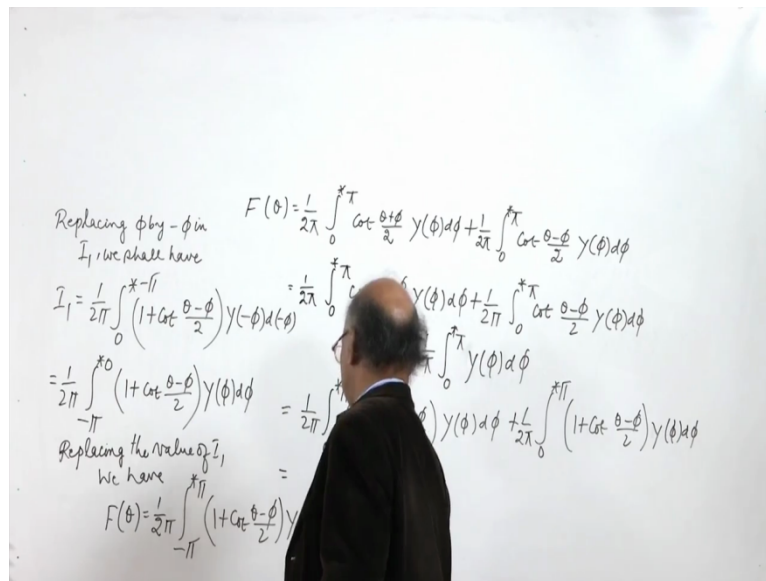

(Refer Slide Time 3:14)

If you can see we can write it as , if you recall in the last lecture we have seen that $\frac{1}{\pi} \int_0^{\pi} Y \phi d \phi$ this we had denoted by c and this we denoted by c , $\frac{1}{\pi} \int_0^{\pi} Y \phi d \phi$ we denoted by c and then we proved that $\frac{1}{\pi} \int_0^{\pi} Y \phi d \phi = 0$, what we had done was, we replaced $Y \phi$ equal to small $Y \phi$ minus c and then we separated the 2 integrals and we got that this value is equal to 0.

So this can be if we add it here we are actually adding 0, so $\frac{1}{\pi} \int_0^{\pi} Y \phi d \phi$, if we add this here actually we are adding 0, so there is no change so I can write it $\frac{1}{2\pi}$ and then again we can write it half , half of this with this and half of this with this and so I can get $\int_0^{\pi} \frac{1}{2\pi} (1 + \cot \frac{\theta + \phi}{2}) Y \phi d \phi$ plus $\frac{1}{2\pi} \int_0^{\pi} (1 + \cot \frac{\theta - \phi}{2}) Y \phi d \phi$. So this is how we arrive here by distributing half of this with this integral half of this with this integral, so this is how we come to this place and then we can write it as, now let us combine the 2 integrals, okay.

(Refer Slide Time 5:55)

So what we will do again? Let us call them as say again I_1 and I_2 , let also plays ϕ by minus ϕ in I_1 , replacing ϕ by minus ϕ in I_1 we shall have I_1 equal to $\frac{1}{2\pi} \int_{-\pi}^0 \left(1 + \cot \frac{\theta-\phi}{2}\right) \gamma(-\phi) d(-\phi)$, okay. $\theta - \phi$ is $\theta - (-\phi)$, so I can write it as $\frac{1}{2\pi} \int_{-\pi}^0 \left(1 + \cot \frac{\theta-\phi}{2}\right) \gamma(\phi) d\phi$, so we get this.

So I_1 is $\frac{1}{2\pi} \int_{-\pi}^0 \left(1 + \cot \frac{\theta-\phi}{2}\right) \gamma(\phi) d\phi$, so this integral can be replaced by that and then we can combine, so replacing the value of I_1 we have $F(\theta)$ equal to $\frac{1}{2\pi} \int_{-\pi}^{+\pi} \left(1 + \cot \frac{\theta-\phi}{2}\right) \gamma(\phi) d\phi$, so we get this $F(\theta)$ equal to $\frac{1}{2\pi} \int_{-\pi}^{+\pi} \left(1 + \cot \frac{\theta-\phi}{2}\right) \gamma(\phi) d\phi$.

from the first alternative pair we recall that the second equation there is $\gamma(\theta) = \frac{1}{2\pi} \int_{-\pi}^{+\pi} \cot \frac{\theta-\phi}{2} F(\phi) d\phi$ and also recall that $F(\theta)$ is an even function of θ , so I can write this equation also as $\gamma(\theta) = \frac{1}{2\pi} \int_{-\pi}^{+\pi} \cot \frac{\theta-\phi}{2} F(\phi) d\phi$ because integral over minus π to π of $F(\phi) d\phi$ is equal to 0 because $F(\phi)$ is an odd function, so this integral is same as this integral, so corresponding to this form we have the, corresponding to this form of the integral equation we have this as a solution of the integral equation. So the relation is 1 and 2 together give us the second alternative form of the finite Hilbert transform pair.

(Refer Slide Time 9:17)

we get

$$F(\theta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left\{ 1 + \cot \frac{\theta - \phi}{2} \right\} Y(\phi) d\phi \quad \dots(1)$$

Similarly

$$Y(\theta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \cot \frac{\phi - \theta}{2} F(\phi) d\phi$$

yields us

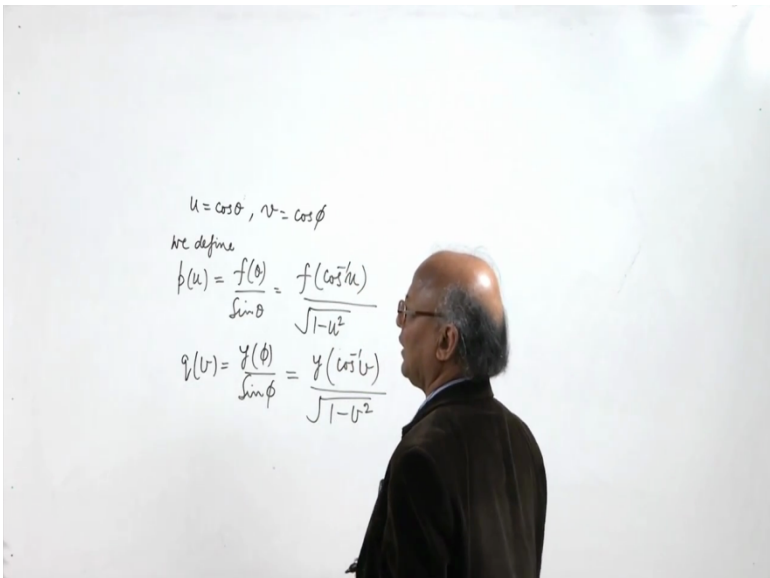

$$Y(\theta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left\{ 1 + \cot \frac{\phi - \theta}{2} \right\} F(\phi) d\phi \quad \dots(2)$$

The relations (1) and (2) give us the second alternative form of finite Hilbert transform pair.

There is one more alternative form which we call third alternative form of Hilbert transform pair, let us recall that. Finite Hilbert transformer of a function $Y(\phi)$ is defined as this $F(\theta)$ equal to one over π integral 0 to π sine θ over $\cos \theta - \cos \phi$ $Y(\phi) d\phi$ where the inverse is given by $Y(\theta)$ equal to one over π integral 0 to π sine ϕ over $\cos \phi - \cos \theta$ $F(\phi) d\phi$ plus 1 over π integral 0 to π $Y(\phi) d\phi$. So this is the Hilbert transform pair.

(Refer Slide Time 10:58)

$u = \cos \theta, v = \cos \phi$
 we define
 $p(u) = \frac{f(\theta)}{\sin \theta} = \frac{f(\cos^{-1} u)}{\sqrt{1-u^2}}$
 $q(v) = \frac{Y(\phi)}{\sin \phi} = \frac{Y(\cos^{-1} v)}{\sqrt{1-v^2}}$

Let us now derive the third alternative form of this. What we do is, we introduce the new variables u by equations u equal to $\cos \theta$ and v equal to $\cos \phi$ and also we define the functions $p(u)$ equal to $F(\theta)$ over $\sin \theta$, so when u is $\cos \theta$, θ will be $\cos^{-1} u$

u, so f of cos inverse u we have and then sine theta will be equal to under root 1 minus u square.

Here we have this integral; in this integral we will make the change of variables, so we are defining pu and qv and qv is equal to we define as y phi over sine phi, so y phi over sine phi is y cosine inverse u cosine inverse v divided by under root 1 minus v square now with this change of variables let us say what we get from the first equation? this equation number 3.

(Refer Slide Time 11:43)

Third alternative form of Hilbert transform pair

Let us recall that
the finite Hilbert transform of a function $y(\phi)$ is defined as

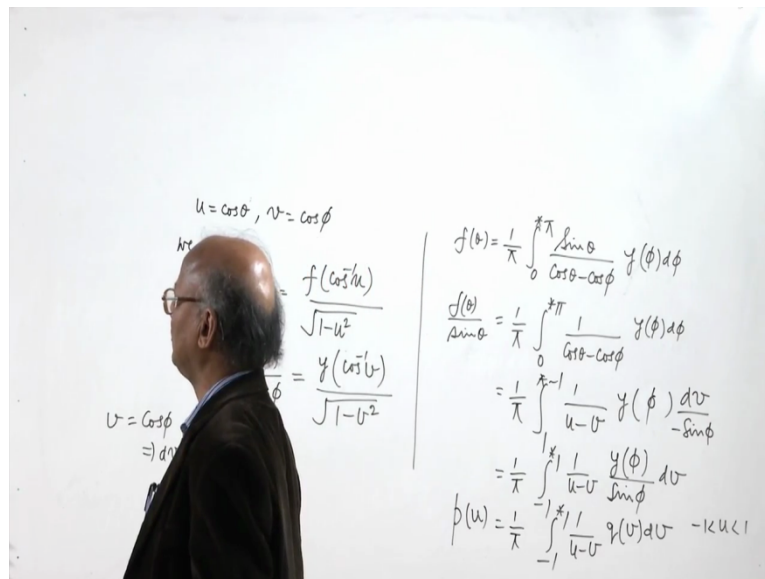

$$f(\theta) = \frac{1}{\pi} \int_0^{\pi} \frac{\sin \theta}{\cos \theta - \cos \phi} y(\phi) d\phi, \quad \dots(3)$$

with the inverse

$$y(\theta) = \frac{1}{\pi} \int_0^{\pi} \frac{\sin \phi}{\cos \phi - \cos \theta} f(\phi) d\phi + \frac{1}{\pi} \int_0^{\pi} y(\phi) d\phi. \quad \dots(4)$$

IT 6008EE NPTEL ONLINE CERTIFICATION COURSE 4

(Refer Slide Time 12:17)

So $F(\theta)$ is equal to $\frac{1}{\pi} \int_0^{2\pi} \frac{\sin \theta}{\cos \theta - \cos \phi} y(\phi) d\phi$. θ is independent of ϕ , so I can divide this equation by $F(\theta)$ so I get $F(\theta)$ upon $\sin \theta$ equal to $\frac{1}{\pi} \int_0^{2\pi} \frac{1}{\cos \theta - \cos \phi} y(\phi) d\phi$. $\cos \theta = u$, $\cos \phi = v$ gives us $dv = -\sin \phi d\phi$, so let us replace the value of $d\phi$ here, so this will be equal to $\frac{1}{\pi} \int_{\pi-\theta}^{\pi+\theta} \frac{1}{u-v} y(\phi) \frac{dv}{-\sin \phi}$. The limits of integration will become $\cos \theta = u$, $\cos \phi = v$, $y(\phi) = y(\cos^{-1} v)$ and $d\phi = \frac{dv}{-\sin \phi}$ and here the limits of integration will become -1 to 1 .

So we can write it as $\frac{1}{\pi} \int_{-1}^1 \frac{1}{u-v} y(v) dv$, y and $\sin \phi$ is equal to $\sqrt{1-v^2}$ this will be $y(\phi)$, okay. I can write it as $y(v)$ I can write it as $y(\cos^{-1} v)$ or I can say $y(\phi)$ over $\sin \phi$ is $\cos^{-1} v$ so $y(\phi)$ over $\sin \phi$ I can write dv , these are same things, okay. So this is nothing but ϕ you can keep it as Φ .

(Refer Slide Time 15:21)

Third alternative form is deduced by introducing variables u and v as follows:

$$u = \cos \theta, \quad v = \cos \phi$$

$$p(u) = \frac{f(\theta)}{\sin \theta} = \frac{f(\cos^{-1} u)}{(1-u^2)^{1/2}} \quad \text{and} \quad q(v) = \frac{y(\phi)}{\sin \phi} = \frac{y(\cos^{-1} v)}{(1-v^2)^{1/2}}.$$

Then (3) \Rightarrow

$$p(u) = \frac{1}{\pi} \int_{-1}^{+1} \frac{q(v)}{u-v} dv, \quad -1 < u < 1 \quad \dots(5)$$

this is also known as **airfoil equation**.

Let me write it phi, okay. So $y(\phi)$ over $\sin \phi$ we can write as $q(v)$, so 1 over π minus 1 to 1 , 1 over u minus v and then $q(v)dv$ and u varies from -1 to 1 because θ varies from 0 to π , so $-1 < u < 1$. So $p(u)$ this first equation, first equation of $F(\theta)$ equal to this can be rewritten as this $F(\theta)$ upon $\sin \theta$ is $p(u)$, so $p(u)$ equal to 1 over π integral over -1 to 1 $q(v)$ over $u-v$ dv , this equation is also known as airfoil equation.

(Refer Slide Time 15:35)

Third alternative form of Hilbert transform pair

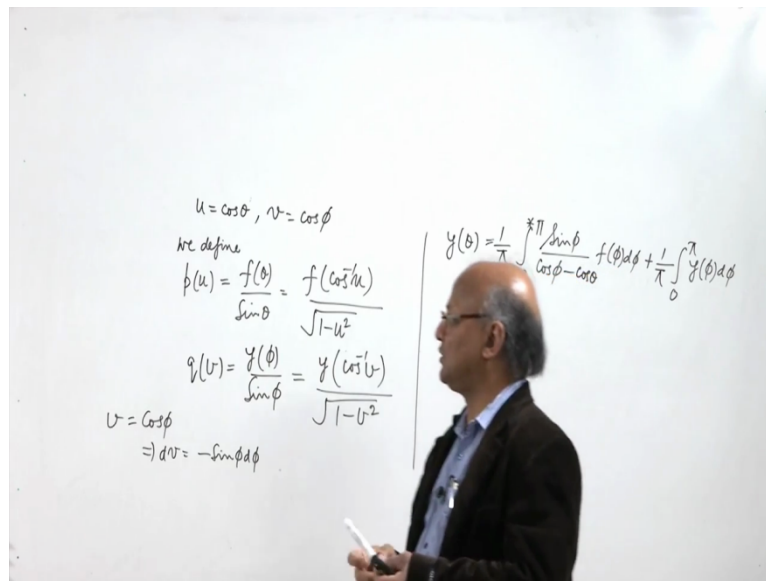

Let us recall that the finite Hilbert transform of a function $y(\phi)$ is defined as

$$f(\theta) = \frac{1}{\pi} \int_0^{\pi} \frac{\sin \theta}{\cos \theta - \cos \phi} y(\phi) d\phi, \quad \dots(3)$$

with the inverse

$$y(\theta) = \frac{1}{\pi} \int_0^{\pi} \frac{\sin \phi}{\cos \phi - \cos \theta} f(\phi) d\phi + \frac{1}{\pi} \int_0^{\pi} y(\phi) d\phi. \quad \dots(4)$$

(Refer Slide Time 16:13)

(Refer Slide Time 16:28)

Similarly,

$$q(u) = \frac{1}{\pi} \int_{-1}^{+1} \left(\frac{1-v^2}{1-u^2} \right)^{1/2} \frac{p(v)}{v-u} dv + \frac{C}{(1-u^2)^{1/2}}, \quad -1 < u < 1 \quad \dots(6)$$

where

$$C = \frac{1}{\pi} \int_{-1}^{+1} q(v) dv, \quad \text{which is an arbitrary constant.}$$

Relations (5) and (6) give the third alternative form of finite Hilbert transform.

6

Now similarly let us go to the second equation. this equation $y(\theta) = \frac{1}{\pi} \int_0^{\pi} \frac{p(v) dv}{\cos \theta - \cos v} + \frac{1}{\pi} \int_0^{\pi} \frac{q(\phi) d\phi}{\cos \theta - \cos \phi}$, so let us write the form of this, now making use of this change of variables and so what we will get is equal to this. Let us see how we get this $q(u) = \frac{1}{\pi} \int_{-1}^{+1} \left(\frac{1-v^2}{1-u^2} \right)^{1/2} \frac{p(v)}{v-u} dv + \frac{C}{(1-u^2)^{1/2}}$, like this.

So what we do is, we again divide by $\sin \theta$ so $y(\theta) / \sin \theta = \frac{1}{\pi} \int_0^{\pi} \frac{p(v) dv}{\cos \theta - \cos v} + \frac{1}{\pi} \int_0^{\pi} \frac{q(\phi) d\phi}{\cos \theta - \cos \phi}$. Now $q(v)$ is $1 / \sin \theta$ over $\cos \theta - \cos \phi$,

okay. So when we have $y \theta$ over $\sin \theta$ we shall write qu because pu , u is a function of θ , so $y \theta$ over $\sin \theta$ we shall write as qu .

So this is qu equal to now here 1 over $\pi d\phi$, what do we get? $d\phi$ is equal to $\sin \phi d\phi$ is equal to dv , so $\sin \phi$ and $d\phi$ we write as dv and this is f of ϕ , okay. So we can write it as dv for $\sin \phi d\phi$ and here we will write $\cos \phi - \cos \theta$ $\cos \phi$ is equal to $b - u$, what we are left with? $f \phi$ is equal to $\frac{pv}{v \sin \phi}$ because v is a function of ϕ .

So $\frac{pv}{v \sin \phi}$ is equal to $\frac{f \phi}{\sin \phi}$, so $f \phi$ is $pv \sin \phi$ the limits of integration will be $\cos \phi$ is equal to b , so there will be 1 to $\cos \theta$ and we shall have $\sin \theta$ here plus 1 over π , here also $y \phi$, $y \phi$ is equal to $qv \sin \phi$, so we have ϕ the limits of integration for ϕ are 1 to $\cos \theta$ and $y \phi$ is equal to $qv \sin \phi$, over $\sin \theta d\phi \sin \phi d\phi$ $\sin \phi dv$, so this will $\sin \phi dv$ so this will $\sin \phi dv$ we will get and this will change to $\cos \theta$ to 1 and we will have this as $\frac{1}{\pi} \int_{\cos \theta}^1 \frac{pv \sin \phi}{v \sin \phi} dv$ this will be $\frac{1}{\pi} \int_{\cos \theta}^1 \frac{p}{v} dv$ and what we will get then?

$\frac{p}{v}$ upon $v - u$ square root $1 - v$ square upon $1 - v$ square into dv , this is for the first integral and second integral will be $\frac{1}{\pi} \int_{\cos \theta}^1 \frac{q}{v \sqrt{1 - v^2}} dv$ $\sqrt{1 - u^2}$ $\sin \theta$ is under root $1 - u^2$, so let us see what we have? Okay, so now what we will do is, because this u is independent of v , so we can also write it as qu equal to $\frac{1}{\pi} \int_{\cos \theta}^1 \frac{p}{v \sqrt{1 - v^2}} dv + c$ upon $\sqrt{1 - u^2}$, where c is the integral, $\frac{1}{\pi} \int_{\cos \theta}^1 \frac{q}{v} dv$.

(Refer Slide Time 21:58)

Similarly,

$$q(u) = \frac{1}{\pi} \int_{-1}^{+1} \left(\frac{1-v^2}{1-u^2} \right)^{1/2} \frac{p(v)}{v-u} dv + \frac{C}{(1-u^2)^{1/2}}, \quad -1 < u < 1 \quad \dots(6)$$

where

$$C = \frac{1}{\pi} \int_{-1}^{+1} q(v) dv, \quad \text{which is an arbitrary constant.}$$

Relations (5) and (6) give the third alternative form of finite Hilbert transform.

6

So $q(u)$ is equal to $\frac{1}{\pi} \int_{-1}^{+1} \left(\frac{1-v^2}{1-u^2} \right)^{1/2} \frac{p(v)}{v-u} dv$ and then c upon under root $1-u^2$ c is given by this expression which is an arbitrary constant. Now this equation which gives us the solution of the integral equation this together makes a Hilbert transform pair third alternative form. So this equation is the equation where we are looking for the solution that is a function q and that solution is given by this equation. So the equation 5 and 6 together give us the third alternative form of the finite Hilbert transform.

(Refer Slide Time 22:51)

Infinite Hilbert transform

The infinite Hilbert transform is defined as

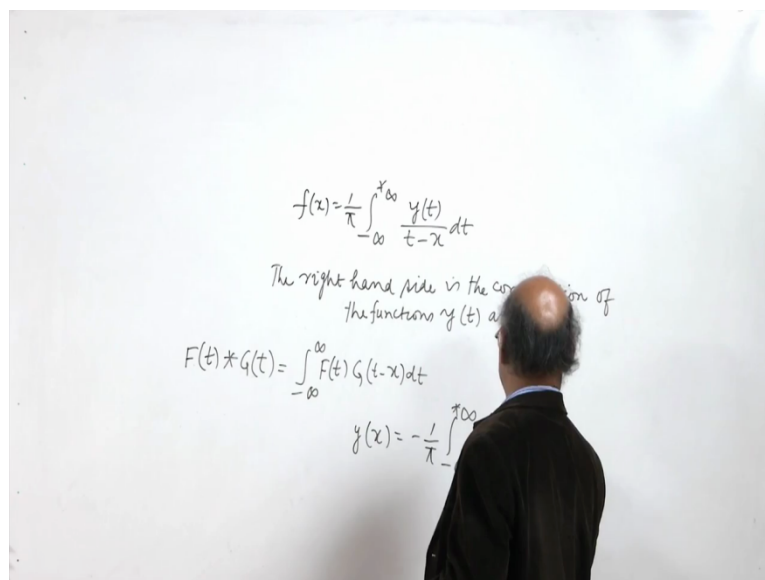

$$f(x) = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{y(t)}{t-x} dt$$

and its inverse

$$y(x) = -\frac{1}{\pi} \int_{-\infty}^{\infty} \frac{f(t)}{t-x} dt.$$

III ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

(Refer Slide Time 23:20)

Now let us go to the definition of in finite Hilbert transform. In finite Hilbert transform is defined as $f(x)$ equal to $\frac{1}{\pi}$ upon π minus infinity to infinity $y(t)$ over t minus x dt . You can see here that $f(x)$ equal to $\frac{1}{\pi}$ minus infinity to infinity $y(t)$ over t minus x dt , this is nothing but the right-hand side is the convolution of the function $y(t)$ with the function $\frac{1}{\pi t}$.

So this right-hand side is a convolution of the functions $y(t)$ and $\frac{1}{\pi t}$. If you recall how we defined the convolution of 2 functions $f(t)$ and $g(t)$ convolution of 2 functions $F(t)$ and $G(t)$ is defined as $F(t) * G(t)$ equal to integral over minus infinity to infinity $F(t)G(t-x) dt$, so right-hand side is the convolution of $y(t)$ and the function is $\frac{1}{\pi t}$ and its inverse that is

the solution of this integral equation is given by $y(x)$ equal to minus 1 over pi. So solution is $y(x)$ equals to minus 1 over pi integral over minus infinity to infinity $f(t)$ over $t - x$ dt. So the unknown function in the integral equation $y(t)$ is determined by the the question giving is the inverse that is $y(x)$ equals to minus 1 over pi integral over minus infinity to infinity $f(t)$ over $t - x$ dt.

(Refer Slide Time 25:23)

Example:
Solve the homogeneous integral equation

$$\int_{-1}^{+1} \frac{q(v)}{u-v} dv = 0.$$

Solution: Using the third alternative form of Hilbert transform, we have

$$p(u) = 0$$

and hence the required solution is given by

$$q(u) = \frac{C}{(1-u^2)^{1/2}}.$$

We will take an equation and see how we will solve this, let us look at this homogenous integral equation because here the function $f(x)$ is a 0. So let us go to a third alternative form Hilbert transform pair, this one. Third alternative form of the Hilbert transform pair, so $p(u)$ actually is taken as 0 here in this example, this is the case of finite Hilbert transform not of infinite Hilbert transform.

(Refer Slide Time 26:26)

So in this equation we are given that integral over minus 1 to 1 principal value of the integral $q(v)dv$ over $u-v$ is equal to 0. Now let us compare it with the third alternative form of the finite Hilbert transform, so this is the equation $p(u)$ equal to one over π integral over minus 1 to 1 $q(v)dv$ upon $u-v$. So if you compare the given equation with this equation we have $p(u)$ equal to 0.

Now let us see the the solution of the integral equation is given by $q(u)$ is equal to one over π integral over minus 1 to 1 under root $1-v^2$ upon $1-u^2$ $p(v)dv$ divided by $v-u$ plus c upon under root $1-u^2$, u belongs to minus 1,1. Now we know that from this equation we know that $p(u)$ equals to 0 over the interval minus 1 to 1. We are even that $p(u)$ equals to 0 for the integral minus 1, 1.

(Refer Slide Time 28:38)

Example:
Solve the homogeneous integral equation

$$\int_{-1}^{+1} \frac{q(v)}{u-v} dv = 0.$$

Solution: Using the third alternative form of Hilbert transform, we have

$$p(u) = 0$$

and hence the required solution is given by

$$q(u) = \frac{C}{(1-u^2)^{1/2}}.$$

IIIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So let us put it in this equation, here we put pu equals to 0 pv vary from minus 1 to 1. So the first expression becomes 0 and what we get? c upon under root 1 minus u square, so where c is the c is given by c is an arbitrary constant, 1 over π integral over minus 1 to 1 $qvdv$, so here the solution of this equation the homogenous integral equation is given by qu equals to see upon under root 1 minus u square. So this is how we solve this example by making use of the third alternative form of this Hilbert transform pair.

With this I would like to conclude my lecture, thank you very much for your attention.
