Lecture 44

Euler's equation: A Particular Case and Geodesics

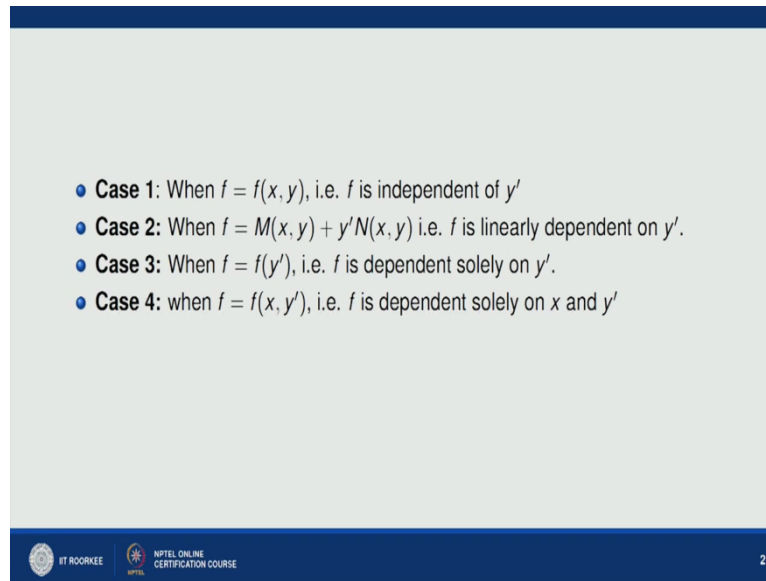

(Refer Slide Time: 0:32)

Hello friends welcome to the today's lecture. In previous class if you remember we have discussed the this kind of functional, let us call it  $J$  of  $y$  of  $x$  is equal to say  $x$  not to  $x_1$ ,  $f$  of  $x$ ,  $y$ ,  $y$  dash,  $d$  of  $x$  such that  $y$  of  $x$  not is equal to  $y_1$  and  $y$  of  $x_1$  equal to  $y$  of  $x$  not equal to  $y$  not and  $y$  of  $x_1$  is equal to  $y$  of  $1$  and we have discussed the Euler's equation which gives the necessary condition that the curve  $y$  is an extremum for this functional  $Jy$  and it is coming out to be that Euler's equation for this is reduced to your  $f$  of  $y$  minus  $d$  by  $dx$  of  $f$  of  $y$  dash is equal to  $0$ .

So basically it is a second-order differential equation in terms of  $y$  and so this equation represents the solution of this equation represents the curve which extremizes the given function this, okay. So in previous class we have derived this equation and we have discussed certain subcases of this, in fact we have discussed the following cases.

(Refer Slide Time: 1:52)

• **Case 1:** When  $f = f(x, y)$ , i.e.  $f$  is independent of  $y'$

• **Case 2:** When  $f = M(x, y) + y'N(x, y)$  i.e.  $f$  is linearly dependent on  $y'$ .

• **Case 3:** When  $f = f(y')$ , i.e.  $f$  is dependent solely on  $y'$ .

• **Case 4:** when  $f = f(x, y')$ , i.e.  $f$  is dependent solely on  $x$  and  $y'$

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE 2

If you look at the case 1 when function  $f$  is equal to  $f$  of  $x, y$  it means that  $f$  is independent of  $y'$  and in this case your Euler's equation reduce to your simple finite equation that is derivative of  $f$  with respect to  $y$  is equal to 0 and we have seen that in general it may not have a solution but if the finite equation which we have obtained passes through the boundary points then it will have a  $(\infty)$  (2:20) solutions and we have seen.

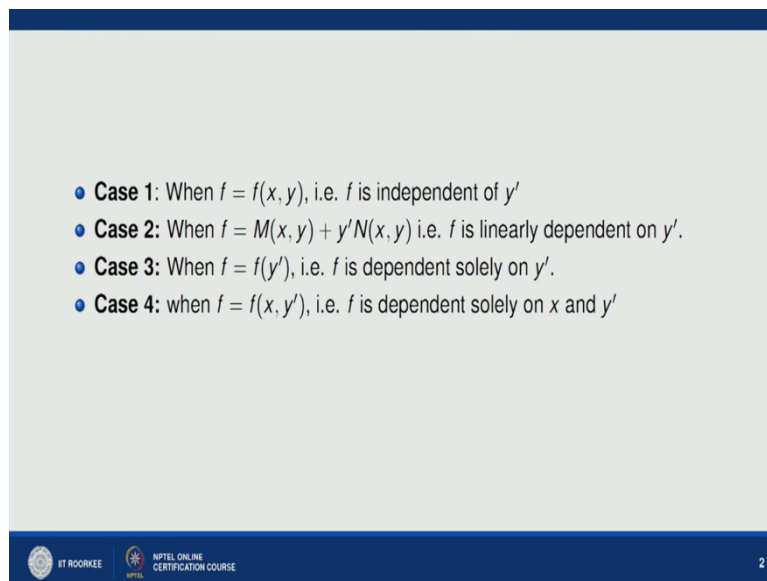

And in the second case when  $f$  is a linearly dependent function on  $y'$ , in this case also we have discussed to sub cases, one that Euler equation reduces to  $M_y$  equal to  $N$  of  $x$  and if this  $M_y$  equal to  $N$  of  $x$  satisfied boundary condition we have a extremal otherwise if  $M_y$  is equal to  $N$  of  $x$  is identically equal to 0 then or we can say that  $M_y$  is equal to  $N$  of  $x$  is there then the extremal is basically coming out to be a constant and it does not depend on any say curve  $y$  of  $x$ .

(Refer Slide Time: 3:18)

So in this case when  $M_y$  is equal to  $N$  of  $x$  then this extremal has this extremal of function has no meaning because it depends only on the end point.

(Refer Slide Time: 3:27)

So in this case, case of 2 there are 2 sub cases and we have discussed these 2 cases, sub cases and examples also based on this and in case 3 when  $f$  is depending only on  $y$  dash, here also we have seen that the already extremal lines are coming out of the straight line is only. So this also we have discussed 1 example also and gays for when  $f$  is equal to  $f$  of  $x, y$  dash that is  $f$  is dependent only on  $x$  and  $y$  dash and here we have seen that this, in this case your Euler's

equation reduce to differential equation depending on  $y'$  and we have discussed certain cases also.

(Refer Slide Time: 4:08)

**Case 5:** When  $f = f(y, y')$ , i.e.  $f$  is independent of  $x$   
 Then Euler's equation  $f_y - f_{xy'} - y'f_{yy'} - y''f_{y'y'} = 0$  gives  $f_y - y'f_{yy'} - y''f_{y'y'} = 0$ .  
 On multiplying this equation by  $y'$ , the left hand side becomes an exact derivative  $\frac{d}{dx}(f - y'f_{y'})$ . In fact,

$$\begin{aligned} \frac{d}{dx}(f - y'f_{y'}) &= f_y y' + f_{y'} y'' - f_{y'} y'' - f_{yy'} y'^2 - f_{y'y'} y' y'' \\ &= y'(f_y - y'f_{yy'} - y''f_{y'y'}) \end{aligned}$$

Hence Euler's equation has the first integral

$$f - y'f_{y'} = C$$

3

Now in this lecture will start with the case 5. So here since  $f$  is independent of  $x$  then this term  $f$  of  $xy'$  dash is coming out to be 0 and this reduces to  $f$  of  $y$  minus  $y'$  dash,  $f_{yy}$  dash minus  $y'$  double dash  $f_{yy'}$  dash  $y'$  dash equal to 0. So here if we observe carefully than if you multiply that, after multiplying this equation this differential equation by  $y'$  dash this becomes an exact derivative of  $f$  minus  $y'$  dash,  $f$  of  $y'$  dash.

Here we can check that if we expand this form  $d$  by  $dx$  of  $f$  minus  $y'$  dash,  $f_{yy}$  dash then we can say that since  $f$  is a function of  $y$  and  $y'$  dash only then derivative of with respect to  $x$  will be  $f$  of  $y$ ,  $y'$  dash plus  $f$  of  $y'$  dash,  $y'$  double dash. So that is the total derivative of  $f$  with respect to  $x$  minus now we are finding out  $d$  by  $dx$  of  $y'$  dash,  $f$  of  $y'$  dash. Now  $f$  of  $y'$  dash and we are taking the derivative of  $y'$  dash with respect to  $d$  with respect to  $x$  then it is coming out to by  $y'$  double dash minus  $f_{yy}$  dash,  $y'$  dash square minus  $f$  of  $y'$  dash  $y'$  dash,  $y'$  dash and  $y'$  double dash.

(Refer Slide Time: 5:32)

**Case 5:** When  $f = f(y, y')$ , i.e.  $f$  is independent of  $x$   
Then Euler's equation  $f_y - f_{xy'} - y'f_{yy'} - y''f_{y'y'} = 0$  gives  $f_y - y'f_{yy'} - y''f_{y'y'} = 0$ .  
On multiplying this equation by  $y'$ , the left hand side becomes an exact derivative  $\frac{d}{dx}(f - y'f_{y'})$ . In fact,

$$\begin{aligned}\frac{d}{dx}(f - y'f_{y'}) &= f_y y' + f_{y'y'} y'' - f_{y'y'} y'' - f_{yy'} y'^2 - f_{y'y'} y' y'' \\ &= y'(f_y - y'f_{yy'} - y''f_{y'y'})\end{aligned}$$

Hence Euler's equation has the first integral

$$f - y'f_{y'} = C$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

Now here these 2 terms, this and this will, these 2 terms this and this will cancel each other and this reduces to this form where we can take out this  $y'$  common in and it is nothing but this. So Euler's equation when  $f$  is independent of  $x$  is precisely the value of this quantity is equal to 0. So it means that if this quantity is equal to 0 this implies that  $d$  by  $dx$  of  $f$  minus  $y'$  dash,  $f_y$  dash is also equal to 0.

So if you solve this, if we integrate this  $d$  by  $dx$  of  $f$  minus  $y'$  dash of  $y'$  dash equal to 0 with respect to  $x$ , we can say that we have this equation  $f$  minus  $y'$  dash,  $f$  of  $y'$  dash equal to  $C$ . So this is our first order differential equation in terms of  $y'$  dash and this does not contain your the variable  $x$  in explicit manner. We can solve this equation with respect to  $y'$  dash and with the usual method with the introduction of any kind of parameter.

(Refer Slide Time: 6:42)

**Example over fifth case**

**Minimum surface of revolution problem:** Find the curve with fixed boundary points such that its rotation about the axis of abscissae give rise to a surface of revolution of minimum surface area.

The area of the surface of revolution is

$$I[y(x)] = 2\pi \int_{x_0}^{x_1} y \sqrt{1 + y'^2} dx.$$

The integrand is independent of  $x$  therefore Euler's equation have the form

$$f - y' f_{y'} = C_1$$

$$y \sqrt{1 + y'^2} - \frac{yy'^2}{\sqrt{1 + y'^2}} = C_1$$

$$\frac{y}{\sqrt{1 + y'^2}} = C_1$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So let us take an example based on this and see how important is this case is? So the example is minimum surface of revolution problem. So here the problem is to find out the curve with fixed boundary points such that its rotation about the abscissae gives rise to a surface of revolution of minimum surface area.

(Refer Slide Time: 7:01)

$$J(y)(x) = \int_{x_0}^{x_1} f(x, y, y') dx.$$

$$y(x_0) = y_0 \text{ \& \ } y(x_1) = y_1$$
 Euler's eq
 
$$b_y - \frac{d}{dx} (b_{y'}) = 0$$

$$b_{y'} = -b_{y'y}$$

$$J(y) = \int_{x_0}^{x_1} 2\pi y \frac{d}{dx} dx = \int_{x_0}^{x_1} 2\pi y \sqrt{1 + y'^2} dx.$$

For example if I look at here, so we have this I think have already discussed this problem. Let us say we have a curve like this, this is your point  $x$  not and this is a point your  $x_1$  and if we this is  $y$  of  $y$  of  $x$  and here if we revolve this curve along this axis  $x$  then you will get a

surface like this and we want to find out that under what curve, this under what curve this  $y$  equal to  $y$  of  $x$ , the surface area of this shape is minimum.

So here to find out the surface area, it is what we try to do, we simply take a small element and this is your  $y$  of this is  $y$ . So surface area is going to be your  $2\pi y$   $d$  of  $s$ , so you can say that your surface area between  $x$  not to  $x_1$  you can calculate it like this,  $x$  not to  $x_1$ ,  $2\pi y$  of  $ds$  and let us call this as a functional based on  $y$ . So  $J$  of  $y$  represents the surface area on this revolve shape and it is given by  $x$  not to  $x_1$ ,  $2\pi y$  of  $ds$ .

So it means that if you change your  $y$ , your surface area is going to change and hence the value of this integral will also change. Now we want to find out say curve  $y$  such that this integral or you can say this functional is minimal. So here let us simplify this, so here we have  $x$  not  $x_1$ , this  $2\pi y$  and  $ds$  you can write it  $ds$  by  $dx$  and  $d$  of  $dx$  here and this  $ds$  by  $dx$  can find out as  $1$  plus  $dy$  by  $dx$  whole square and  $d$  of  $x$  values of  $x$  is  $x$  not to  $x_1$ .

Here, in fact you can write it here the points say  $s_1$  and  $s_2$  which is corresponding to the point when  $x$  is equal to  $x$  not and  $x$  is equal to  $x_1$ , so we want to minimize this functional. So here if you look at this is nothing but a functional this is the functional independent of say  $x$ . So here your  $x$  is not present, so here this case is coming under the sub case 5 and here in this case we have defined here  $I$ , we have discussed his  $(())$  (9:34).

(Refer Slide Time: 9:49)

Example over fifth case

**Minimum surface of revolution problem:** Find the curve with fixed boundary points such that its rotation about the axis of abscissae give rise to a surface of revolution of minimum surface area.

The area of the surface of revolution is

$$I[y(x)] = 2\pi \int_{x_0}^{x_1} y \sqrt{1 + y'^2} dx.$$

The integrand is independent of  $x$  therefore Euler's equation have the form

$$f - y' f_{y'} = C_1$$
$$y \sqrt{1 + y'^2} - \frac{yy'^2}{\sqrt{1 + y'^2}} = C_1$$
$$\frac{y}{\sqrt{1 + y'^2}} = C_1$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So here we have seen that the surface of the revolution, the area of the surface of the revolution is given by  $J$  of  $y$  of  $x$  equal to  $2\pi \int_{x_0}^{x_1} y \sqrt{1 + y'^2} dx$ . So as we have discussed here that this Euler equation is reduced to this that  $f$  minus  $y'$  of  $f$  of  $y'$  is equal to  $C_1$ . So here  $f$  is  $y \sqrt{1 + y'^2}$ .

So if you simplify this  $f$  is  $y \sqrt{1 + y'^2}$  and then if you differentiate this with respect to  $y'$  you will get this and after simplifying you have  $y$  upon  $\sqrt{1 + y'^2}$  is equal to  $C_1$ . So basically this is a kind of a first order differential equation, we may further simplify it by squaring it on both the sides.

(Refer Slide Time: 10:44)

Example over fifth case

**Minimum surface of revolution problem:** Find the curve with fixed boundary points such that its rotation about the axis of abscissae give rise to a surface of revolution of minimum surface area.

The area of the surface of revolution is

$$I[y(x)] = 2\pi \int_{x_0}^{x_1} y \sqrt{1 + y'^2} dx.$$

The integrand is independent of  $x$  therefore Euler's equation have the form

$$f - y' f_{y'} = C_1$$
$$y \sqrt{1 + y'^2} - \frac{yy'^2}{\sqrt{1 + y'^2}} = C_1$$
$$\frac{y}{\sqrt{1 + y'^2}} = C_1$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So here we have this we can solve by squaring it and then find out a differential equation in terms of  $y$  dash or a simpler method we can evolve by saying that if we take  $y$  dash in a way that let us say  $y$  dash is equal to  $\sinh t$ , so if we take  $y$  dash as  $\sinh t$  then  $1 + \sinh^2 t$  is basically  $\cosh^2 t$ , so here under root is there, so you can take that if  $y$  dash is  $\sinh t$  then  $y$  is coming out to be  $C_1 \cosh t$ .

(Refer Slide Time: 11:09)

To solve this integration, let  $y' = \sin ht$ , then  $y = C_1 \cos ht$ , and  $dx = \frac{dy}{y'} = C_1 dt$  i.e.  $x = C_1 t + C_2$ . And the desired surface is formed by revolution of a line given in parametric form

$$\begin{aligned}x &= C_1 t + C_2 \\y &= C_1 \cos ht.\end{aligned}$$

On eliminating the parameter  $t$ , we get  $y = C_1 \cos h\left(\frac{x-C_2}{C_1}\right)$ , a family of catenaries, the revolution of which forms surfaces called catenoids.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

So you can write it here let  $y'$  equal to  $\sin$  hyperbolic  $t$  then  $y$  is coming out to be  $C_1 \cos$  hyperbolic  $t$  and we can find out say variable  $d$  of  $x$  as  $dy$  by upon  $y'$  and  $dy$  you can calculate,  $dy \sin$  hyperbolic  $t$  and  $y'$  you can simply say that it is coming out to be  $C_1 dt$  and when you integrate it, it is coming out to be  $x$  of  $x$  is equal to  $C_1 t$  plus  $C_2$ . So here your curve is given in terms of parametric form that is  $y$  equal to  $C_1 \cos$  hyperbolic  $t$  and  $x$  equal to  $C_1 t$  plus  $C_2$ .

So this after removing, so this is a parameter representation of a curve which minimises the surface area of revolution and we can simply find out the relation between  $y$  and  $x$  by removing the parametric  $t$  here. So you can find out the value of  $t$  here as  $x$  minus  $C_2$  divided by  $C_1$ . So your equation of the extremal curve is given as  $y$  equal to  $C_1 \cos$  hyperbolic,  $x$  minus  $C_2$  upon  $C_1$ .

And this curve basically represent the family of catenaries and shape which we obtain by the revolution this catenaries is called get Catenoids. And here if you remember here we have 2 constants  $C_1$  and  $C_2$  that we can obtain satisfying the condition that  $y$  of  $x$  not is equal to  $y$  not and  $y$  of  $x_1$  is equal to  $y_1$ . So this  $C_1$  and  $C_2$  you can obtain in terms of  $x$  not and  $y$  not and please remember here we can solve these equations, this equation  $y$  upon under root 1 plus  $y'$  square equal to  $C_1$  by squaring and simplifying for  $y$  and  $y'$ .

(Refer Slide Time: 13:08)

$$J(y) = \int_{x_0}^{x_1} f(x, y, y') dx$$

$$y(x_0) = y_0 \text{ \& \ } y(x_1) = y_1$$
 Euler's eq
 
$$b_y - \frac{d}{dx} (b_{y'}) = 0$$

$$b_{y'} = b_{x y'} - b_{y y'}$$

$$\frac{y}{\sqrt{1+y'^2}} = c_1$$

$$y^2 = c_1^2 (1+y'^2)$$

$$\Rightarrow y'^2 = \frac{y^2 - c_1^2}{c_1^2}$$

$$y' = \frac{\pm \sqrt{y^2 - c_1^2}}{c_1} \Rightarrow \frac{dy}{\sqrt{y^2 - c_1^2}} = \pm \frac{dx}{c_1} \Rightarrow \cosh^{-1} \left( \frac{y}{c_1} \right) + c_2 = \frac{x}{c_1}$$

$$J(y) = \int_{x_0}^{x_1} 2\pi y \left( \frac{dy}{dx} \right) dx = \int_{x_0}^{x_1} 2\pi y \sqrt{1 + \left( \frac{dy}{dx} \right)^2} dx$$

So this also you can do, in fact let us see here this is your y upon under root 1 plus y dash square. I'm just giving you a small hint how you can solve it, right? If you square it you have y square equal to C1 square 1 plus y dash square, right? And you can simply say that it is y dash square is equal to you can say that it is y square minus C1 square and divided by basically C1 square.

So here you can say that y dash is equal to under root y square minus C1 square 1 upon C1. So here this you can say that it is dy by under root y square minus C1 square is equal to 1 upon C1, d of x and if you integrate on both the sides then you will get this as what is that? This is cause hyperbolic inverse y by C1 plus C2 is equal to say x by C1. So if you simplify you will get the, that the similar kind of relation you're getting and you can simplify and you can get the value of y, is it okay? So here this is example based on the case 5.

(Refer Slide Time: 14:35)

**Geodesics**

A geodesic on a surface is a curve along which the distance between two points of the surface is a minimum.

◦ **Example 1:** Show that the geodesics on a plane are straight lines.  
Let  $y = y(x)$  be a curve joining the points  $A(x_1, y_1)$  and  $B(x_2, y_2)$  in the  $xy$ -plane. Then the length of a curve joining  $A$  and  $B$  is given by

$$s = \int_A^B ds = \int_{x_1}^{x_2} \frac{ds}{dx} dx = \int_{x_1}^{x_2} \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx.$$

The geodesic on the  $xy$ -plane is the curve  $y = y(x)$  for which  $s$  is minimum. Here  $f(x, y, y') = \sqrt{1 + y'^2}$  i.e. depends on  $y'$  only. Hence Euler's equation gives

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

Now let us take very important example of this Euler's equation and that is the finding the curves which minimises the distance between any 2 points are even surface and there is known as Geodesics. So Geodesics you can define it like this, that Geodesics on a surface is a curve along which the distance between 2 points of the surface is minimum. So what it means?

That you have a surface take 2 points and then you can join these 2 points by some curves which are lying on your surfaces only. So out of those () curves on your surface you need to choose the curves which minimises the distance between A and B along the surface and whatever curve you will get as a minimizer of the distance that curve is known as Geodesics.

So we have seen the first example earlier also but let me famed this example here also. So first example show that the Geodesics on a plane or straight line. So here your surface is your plane. So if we have a planar surface and if you want to find out the geodesics that it is coming out to be a straight line. So how we can form? How we can solve this using the Euler's equation?

So here we have a curve which joints the point A and B where a is denoted as  $x_1y_1$  and B as  $x_2y_2$  in the  $xy$  plane that they can find out see length between A and B as A to B, d of s and d of s you can write it as under root 1 plus dy by dx whole square and so you can say that the functional s represent the length between the point A and B whose x coordinate is given as  $x_1$  and  $x_2$ .

(Refer Slide Time: 16:50)

The slide contains the following mathematical derivations:

$$\frac{d}{dx} \left( \frac{\partial f}{\partial y'} \right) = 0$$
$$\frac{d}{dx} \left( \frac{2y'}{2\sqrt{1+y'^2}} \right) = 0$$
$$y''(1+y'^2) - y'^2 y'' = 0$$
$$\frac{d^2 y}{dx^2} = 0$$

Integrating twice, we obtain  $y = c_1 x + c_2$ , which is a straight line. Hence the geodesics on a plane are straight lines.

At the bottom of the slide, there are logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and a page number 7.

So we have to minimise this functional, right? So the Geodesics on the xy plane is curve y equal to y of x for which this functional s is minimum. So here if you look at the integrand is what? Integrand is under root 1 plus y dash square and which is independent of x and y all we can say depends only on y dash and hence we can use our subcase and we can get the Euler equation is nothing but d by dx of dabba f by dabba y dash equal to 0.

So here we can again pose this equation has dabba f by dabba y dash equal to constant which we have discussed but if you look at the value of dabba f by dabba y dash it is coming out to be 2 y dash upon 2 under root 1 plus y dash square. So when you simplify this than it is coming out to be a second-order differential equation like this but after simplifying it is nothing but only this y double dash is equal to 0.

So this is a second-order differential equation, a very simple second-order differential equation whose solution is nothing but this C1x plus C2. So here this is nothing but only a straight line and C1 and C2 you can obtain by the condition that y of x1 and y of x2 is equal to y 2. So this C1 and C2 you can obtain and you can say that this is nothing but a straight line which passes through your point A and B. So here Geodesics on a plane are nothing but straight lines. So this is something kind of a, we know from long back but here is the mathematical proof for the fact which we already know.

(Refer Slide Time: 18:23)

**Example 2:** Find the geodesics on a right circular cylinder of radius  $r$ .  
Using cylindrical coordinates  $(\rho, \phi, z)$ , we have

$$x = \rho \cos \phi, \quad y = \rho \sin \phi, \quad z = z.$$

Here radius  $\rho = r$  therefore the arc element on a right circular cylinder of radius  $r$  is given by

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 \\ &= (d\rho)^2 + (\rho d\phi)^2 + dz^2 = r^2 d\phi^2 + dz^2 \\ ds &= \sqrt{r^2 + \left(\frac{dz}{d\phi}\right)^2} d\phi \\ s &= \int_{\phi_1}^{\phi_2} \sqrt{r^2 + z'^2} d\phi \end{aligned}$$

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    8

(Refer Slide Time: 18:30)

So let us move to next example which is a little bit nontrivial kind of thing and so example is that find the Geodesics on a right circular cylinder of radius  $r$ . So let me use her, so here we have a right circular cylinder and we have take just 2 points P and Q here on the cylinder and we want to we can connect this P and Q by some curves which are lying on the surface only.

(Refer Slide Time: 19:13)

**Example 2:** Find the geodesics on a right circular cylinder of radius  $r$ .  
Using cylindrical coordinates  $(\rho, \phi, z)$ , we have

$$x = \rho \cos \phi, \quad y = \rho \sin \phi, \quad z = z.$$

Here radius  $\rho = r$  therefore the arc element on a right circular cylinder of radius  $r$  is given by

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 \\ &= (d\rho)^2 + (\rho d\phi)^2 + dz^2 = r^2 d\phi^2 + dz^2 \\ ds &= \sqrt{r^2 + \left(\frac{dz}{d\phi}\right)^2} d\phi \\ s &= \int_{\phi_1}^{\phi_2} \sqrt{r^2 + z'^2} d\phi \end{aligned}$$

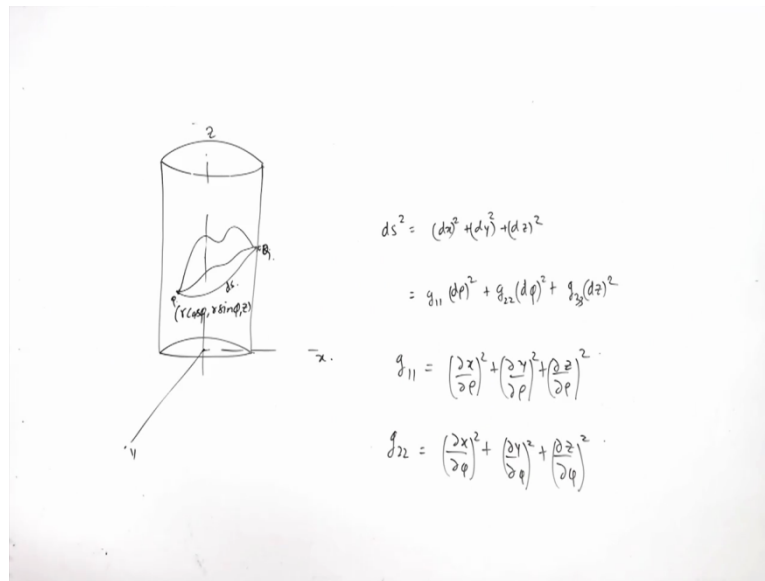

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

So there are several possible curves here and you want to find out say the curve which minimises the distance between P and Q which we are travelling only on this the cylinder, okay. So here we can simply say that how we can find out? So let us use cylindrical coordinates and its Rho, phi and z and here the x coordinate you can write it Rho cos phi and y coordinate is Rho sin phi as z is equal to z.

So any point on your cylinder, cylinder with radius r is given by r cos Phi, r sin phi and z. So here your P is given by the can write it r cos phi, r sin phi and the z here. Now to find out say the surface here let us use this thing that ds square is equal to dx square plus dy square plus dz square basically it is this and we want to find out say length between length of the curve of joining P and Q.

So here if you simplify this dx square dy square plus dz square you can write it in terms of say d square, let me write it here, g11 plus g22 d of phi square plus g of 33 dz square and you can find out gii is equal to say dabba x by dabba rho whole square plus dabba y by dabba rho whole square plus dabba z dabba rho whole square similarly you can write it g22 as dabba x by dabba phi whole square plus dabba y by dabba phi whole square and dabba z upon dabba phi whole square and with the help of this you can easily find out say ds square.

(Refer Slide Time: 19:47)

(Refer Slide Time: 21:20)

**Example 2:** Find the geodesics on a right circular cylinder of radius  $r$ .  
Using cylindrical coordinates  $(\rho, \phi, z)$ , we have

$$x = \rho \cos \phi, \quad y = \rho \sin \phi, \quad z = z.$$

Here radius  $\rho = r$  therefore the arc element on a right circular cylinder of radius  $r$  is given by

$$ds^2 = dx^2 + dy^2 + dz^2$$

$$= (d\rho)^2 + (\rho d\phi)^2 + dz^2 = r^2 d\phi^2 + dz^2$$

$$ds = \sqrt{r^2 + \left(\frac{dz}{d\phi}\right)^2} d\phi$$

$$s = \int_{\phi_1}^{\phi_2} \sqrt{r^2 + z'^2} d\phi$$

So your this thing is coming out, so for right circular cylinder of radius  $r$  your  $ds$  square is coming out  $ds$  square is equal to  $dx$  square plus  $dy$  square plus  $dz$  square and here  $x$  is given as  $\rho \cos \phi$ ,  $y$  is equal to  $\rho \sin \phi$ ,  $z$  equal to  $z$ . So using the formula which we have listed here you can find out say  $g_{11}$ ,  $g_{22}$  and  $g_{33}$  and in this case your  $g_{11}$  is coming out to be  $\frac{\partial x}{\partial \phi} \frac{\partial x}{\partial \phi} + \frac{\partial y}{\partial \phi} \frac{\partial y}{\partial \phi} + \frac{\partial z}{\partial \phi} \frac{\partial z}{\partial \phi}$ .

So  $\frac{\partial x}{\partial \phi} \frac{\partial x}{\partial \phi}$  is coming out to be  $\cos^2 \phi$  and  $\frac{\partial y}{\partial \phi} \frac{\partial y}{\partial \phi}$  is equal to  $\sin^2 \phi$  and  $\frac{\partial z}{\partial \phi} \frac{\partial z}{\partial \phi}$  is simply 0. So in this case your  $g_{11}$  is coming out to be  $\cos^2 \phi + \sin^2 \phi$  that is equal to 1, so  $g_{11}$  is coming out to be 1 here.

Similarly you can find out  $g_{22}$  as  $\frac{\partial x}{\partial \phi}$  by  $\frac{\partial x}{\partial \phi}$  which is  $-\rho \sin \phi$  and  $\frac{\partial y}{\partial \phi}$  by  $\frac{\partial y}{\partial \phi}$  is your  $\rho \cos \phi$  and  $\frac{\partial z}{\partial \phi}$  by  $\frac{\partial z}{\partial \phi}$  is nothing but 0.

So when you find out  $g_{22}$  it is the square of  $\frac{\partial x}{\partial \phi}$  by  $\frac{\partial x}{\partial \phi}$  which is nothing but  $\rho^2 \sin^2 \phi$  plus  $\frac{\partial y}{\partial \phi}$  by  $\frac{\partial y}{\partial \phi}$  square that is  $\rho^2 \cos^2 \phi$ , when you add these 2 it is coming out to be  $\rho^2$ . So you're  $g_{11}$  is coming out to be  $\rho^2$ . So similarly you can find out  $g_{33}$ , so you can say that your  $ds^2$  is given as  $d\rho^2 + \rho^2 d\phi^2 + dz^2$ .

Now for this your  $\rho$  is fixed, so  $\rho$  is given as  $r$ . So you can say that the arc element on a right circular cylinder of radius  $r$  is reduced to only  $r^2 d\phi^2 + dz^2$  because the component along this, this is simply 0 because  $\rho$  is a fixed quantity. So  $ds^2$  is given as  $r^2 d\phi^2 + dz^2$ . So  $ds$  you can write it as  $\sqrt{r^2 d\phi^2 + dz^2}$ .

So here we are assuming that  $z$  is a function of  $\phi$  and it is simplified as your functional arc length is given by  $S = \int_{\phi_1}^{\phi_2} \sqrt{r^2 + \left(\frac{dz}{d\phi}\right)^2} d\phi$ . Now if you look at this is nothing but a function on  $\phi$  and  $z$  and here this is independent of  $\phi$  and  $z$ . So you can take the help of Euler's equation

(Refer Slide Time: 23:52)

The geodesics for a given cylinder is the curve for which  $s$  is minimum. Here  $f = \sqrt{r^2 + z'^2}$  is a function of  $\phi$  and  $z'$ . Therefore Euler's equation reduces to

$$\frac{\partial f}{\partial z'} = \text{constant},$$
$$\frac{z'}{\sqrt{r^2 + z'^2}} = C,$$
$$z' = c_1,$$
$$z = c_1 \phi + c_2.$$

This tells us that geodesics on a right circular cylinder of radius  $r$  are circular helix.

IT ROOKIEE

NPTEL ONLINE CERTIFICATION COURSE

9

And we can say that the Geodesics for a given cylinder is the curve for which  $S$  is minimum and you can say that Euler's equation reduces to  $\frac{\partial f}{\partial z'} = \text{constant}$  and  $f$  is given by  $\sqrt{r^2 + z'^2}$ . So when you plug in this value you will have  $\frac{z'}{\sqrt{r^2 + z'^2}} = C$ . Now you can simplify this.

So here we have  $\frac{z'}{\sqrt{r^2 + z'^2}} = C$ , so you can square it and you can solve it. So after squaring it you have  $z'^2 = C^2(r^2 + z'^2)$ . So you can simplify this, so  $z'^2$  is coming out to be  $C^2 r^2 / (1 - C^2)$ . So here  $C$  is constant,  $r$  is constant, so here this whole quantity is constant.

So you can write it  $z' = C_1$ , so when you solve this then it is coming out to be  $z = C_1 \phi + C_2$ , please remember this  $z'$  here is nothing but  $\frac{dz}{d\phi}$ , okay. So when you integrate this  $z'$  as  $C_1$  you will get  $Z = C_1 \phi + C_2$ . Now again this  $C_1$  and  $C_2$  you can obtain with the help of the initial values that  $P$  and  $Q$  are the initial values, is it okay?

So now if you look at carefully then what is this? So here if you vary your  $\phi$  then of course your height will also change and it is coming out to be that the path which minimises the distance between any 2 point  $P$  and  $Q$  is nothing but Helix on the right circular cone. So here

in this case the Geodesics on a right circular cylinder of radius  $r$  is nothing but circular Helix which is represented by  $z$  equal to  $C_1 \phi$  plus  $C_2$ .

(Refer Slide Time: 26:01)

**Example 2:** Find the geodesics on a right circular cylinder of radius  $r$ .  
Using cylindrical coordinates  $(\rho, \phi, z)$ , we have

$$x = \rho \cos \phi, \quad y = \rho \sin \phi, \quad z = z.$$

Here radius  $\rho = r$  therefore the arc element on a right circular cylinder of radius  $r$  is given by

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 \\ &= (d\rho)^2 + (\rho d\phi)^2 + dz^2 = r^2 d\phi^2 + dz^2 \\ ds &= \sqrt{r^2 + \left(\frac{dz}{d\phi}\right)^2} d\phi \\ s &= \int_{\phi_1}^{\phi_2} \sqrt{r^2 + z'^2} d\phi \end{aligned}$$

BT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

Where  $C_1$  and  $C_2$  is maybe obtained by the initial condition here, here is the initial condition that  $z$  of  $\phi_1$  is equal to  $z_1$  and  $z$  of  $\phi_2$  is equal to  $z_2$ , okay. So moving on say next example.

(Refer Slide Time: 26:16)

**Example 3:** Show that the geodesics on a sphere of radius  $c$  are its great circles. Using spherical coordinates  $(r, \theta, \phi)$ , we have

$$x = r \sin \theta \cos \phi, \quad y = r \sin \theta \sin \phi, \quad z = r \cos \theta.$$

Here  $r = c$  therefore the arc element on a sphere of radius  $c$  is given by

$$ds^2 = dr^2 + (rd\theta)^2 + (r \sin \theta d\phi)^2 = c^2 d\theta^2 + (c \sin \theta)^2 d\phi^2$$
$$ds = c \sqrt{[1 + \sin^2 \theta (d\phi/d\theta)^2]} d\theta$$
$$s = c \int_{\theta_1}^{\theta_2} \sqrt{[1 + \sin^2 \theta (d\phi/d\theta)^2]} d\theta$$

The geodesic on the sphere  $r = c$  is the curve for which  $s$  is minimum. Here

IT ROORKEE

10

So here we want to see that that geodesics on a sphere of radius  $C$  and we want to show that it is nothing but great circle of this sphere. So here to solve this problem we use the spherical coordinates system and that is  $r$ ,  $\theta$ ,  $\phi$ , so here in terms of  $r$ ,  $\theta$ ,  $\phi$  the can write down your  $x$  coordinate as  $r \sin \theta \cos \phi$ ,  $y$  as  $r \sin \theta \sin \phi$  and  $z$  equal to  $r \cos \theta$ .

So here  $\theta$  is the angle made by the radius factor  $z$  axis and  $\phi$  is angle of the projection of radius factor and the angle from the  $x$  axis, okay. So here  $r$  is equal to  $C$ , so similarly as we have done in the previous case your arc element on this sphere is given by  $ds^2$  as  $dx^2$  plus  $dy^2$  plus  $dz^2$  and that you can find out as  $g_{11} dr^2$  plus  $g_{22} d\theta^2$  plus  $g_{33} d\phi^2$  and you can easily calculate  $g_{11}$ ,  $g_{22}$  and  $g_{33}$ , formula is already given in the previous example.

(Refer Slide Time: 28:30)

So but let us take very simple 1,  $g_{11}$ . So  $g_{11}$  is what dabba x by dabba r whole square plus dabba y by dabba r whole square plus dabba z by dabba r whole square. Let me do it here, so here you can write it here your x is equal to  $r \sin \theta \cos \phi$ ,  $y$  equal to  $r \sin \theta \sin \phi$  and  $z$  equal to  $r \cos \theta$ , right? So here you can find out  $g_{11}$  here.

So  $g_{11}$  is dabba x by dabba r, so that is  $\sin \theta \cos \phi$  and dabba y by dabba r is equal to  $\sin \theta \sin \phi$  and dabba z by dabba r is basically your  $\cos \theta$ . So when you find out  $g_{11}$ ,  $g_{11}$  is basically square of these 3 conditions, so when you square these 2 you will get  $\sin^2 \theta$ . So  $\sin^2 \theta \cos^2 \phi$  plus  $\sin^2 \theta \sin^2 \phi$  plus  $\cos^2 \theta$ .

So here when you take  $\sin^2 \theta$  common then this is nothing but  $\cos^2 \phi$  plus  $\sin^2 \phi$  that is 1 and ultimately you will get  $\sin^2 \theta$  plus  $\cos^2 \theta$  that is 1. So here in this case you can get your  $g_{11}$  and similarly you can find out  $g_{22}$  and  $g_{33}$ . So here  $g_{22}$  is nothing but with respect to  $\theta$  you're finding, so your  $g_{22}$  is coming out to be dabba x by dabba  $\theta$  whole square plus dabba y by dabba  $\theta$  whole square plus dabba z by dabba  $\theta$  whole square. So you can find out the value of  $g_{22}$  and similarly  $g_{33}$ .

(Refer Slide Time: 29:55)

**Example 3:** Show that the geodesics on a sphere of radius  $c$  are its great circles. Using spherical coordinates  $(r, \theta, \phi)$ , we have

$$x = r \sin \theta \cos \phi, \quad y = r \sin \theta \sin \phi, \quad z = r \cos \theta.$$

Here  $r = c$  therefore the arc element on a sphere of radius  $c$  is given by

$$ds^2 = dr^2 + (rd\theta)^2 + (r \sin \theta d\phi)^2 = c^2 d\theta^2 + (c \sin \theta)^2 d\phi^2$$
$$ds = c \sqrt{[1 + \sin^2 \theta (d\phi/d\theta)^2]} d\theta$$
$$s = c \int_{\theta_1}^{\theta_2} \sqrt{[1 + \sin^2 \theta (d\phi/d\theta)^2]} d\theta$$

The geodesic on the sphere  $r = c$  is the curve for which  $s$  is minimum. Here

IT ROOKIEE

NPTEL ONLINE  
CERTIFICATION COURSE

10

So you can say that here we have calculated and it is coming out to be that  $ds$  square is equal to  $dr$  square plus  $rd\theta$  whole square plus  $r \sin \theta d\phi$  whole square. Now here as we have taken that radius is constant and it is given as  $C$ . So this  $dr$  is coming out to be 0 and so  $ds$  square is coming you can write it  $C$  square  $d\theta$  square plus  $C$  square  $\sin^2 \theta d\phi$  square.

So this is the arc element on the sphere of radius  $C$  and you can simplify and you can form the functional which gives the arc length between 2 given points A and B and you can say that  $S$  is given as  $C$   $\theta_1$  to  $\theta_2$  under root  $1 + \sin^2 \theta (d\phi/d\theta)^2$  whole square  $d\theta$ . So the Geodesics on the sphere  $r = C$  is the curve for which this functional  $S$  is minimum.

(Refer Slide Time: 30:53)

$$f = c\sqrt{1 + \sin^2 \theta \phi'^2}$$

thus  $f$  is a function of  $\theta$  and  $\phi'$  only. Therefore Euler equation gives

$$\frac{\partial f}{\partial \phi'} = \text{constant}$$
$$\frac{\partial f}{\partial \phi'} = \frac{c \sin^2 \theta \phi'}{\sqrt{1 + \sin^2 \theta \phi'^2}} = \text{constant}$$
$$\frac{\sin^2 \theta \phi'}{\sqrt{1 + \sin^2 \theta \phi'^2}} = a(\text{say})$$
$$\sin^2 \theta (\sin^2 \theta - a^2) \phi'^2 = a^2$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

(Refer Slide Time: 31:02)

$$f = c\sqrt{1 + \sin^2 \theta \phi'^2}$$
$$f = f(\theta, \phi, \phi')$$
$$\frac{\partial f}{\partial \phi} - \frac{d}{d\theta} (b\phi') = 0$$
$$\Rightarrow b\phi' = \text{constant}$$

So here your  $f$  is nothing but  $C$  under root  $1 + \sin^2 \theta, \phi'$  square. So let me write it here your  $f$  is your  $C$  under root  $1 + \sin^2 \theta$  and  $\phi'$  square, so  $\phi'$  square. So here you can say that  $f$  is a function of say your site and  $\phi$  and  $\phi'$ . So here now this is independent of your  $\phi$ , so here your Euler equation for this integrand is basically what  $\frac{\partial f}{\partial \phi} - \frac{d}{d\theta} (b\phi') = 0$ .

(Refer Slide Time: 31:53)

$$f = c\sqrt{1 + \sin^2 \theta \phi'^2}$$

thus  $f$  is a function of  $\theta$  and  $\phi'$  only. Therefore Euler equation gives

$$\frac{\partial f}{\partial \phi'} = \text{constant}$$
$$\frac{\partial f}{\partial \phi'} = \frac{c \sin^2 \theta \phi'}{\sqrt{1 + \sin^2 \theta \phi'^2}} = \text{constant}$$
$$\frac{\sin^2 \theta \phi'}{\sqrt{1 + \sin^2 \theta \phi'^2}} = a(\text{say})$$
$$\sin^2 \theta (\sin^2 \theta - a^2) \phi'^2 = a^2$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

Now since this integrand is independent of  $\phi$ , so this term is simply 0 and you can simply write this as  $f$  of  $\phi'$  is equal to constant. So here we are using this and you can say that Euler equation reduces to  $\frac{df}{d\phi'} = \text{constant}$ . So  $f$  is given you can find out say value of  $\frac{df}{d\phi'}$  is coming out to be  $C \sin^2 \theta$ ,  $\phi'$  divided by  $1 + \sin^2 \theta \phi'^2$  equal to constant.

Now let us take this constant as sum  $a$  and you can simplify this so when you, this is constant divided by  $C$  is your  $a$ . So when you simplify this you can square it and simplify for  $\phi'^2$ , so  $\phi'^2$  is coming out to be a square upon  $\sin^2 \theta$  and  $\sin^2 \theta$  minus  $a^2$ .

(Refer Slide Time: 32:28)

$$\frac{d\phi}{d\theta} = \frac{a}{\sin \theta \sqrt{(\sin^2 \theta - a^2)}} = \frac{a \csc^2 \theta}{1 - a^2 \csc^2 \theta}$$

On integration, we obtain

$$\phi = \int \frac{a \csc^2 \theta d\theta}{\sqrt{[(1 - a^2) - (a \cot \theta)^2]}} + a' = -\sin^{-1} \left\{ \frac{a \cot \theta}{\sqrt{1 - a^2}} \right\} + a'$$

$$\cot \theta = A \cos \phi + B \sin \phi$$

$$c \cos \theta = A c \sin \theta \cos \phi + B c \sin \theta \sin \phi$$

$$z = Ax + By$$

This is a plane through the centre (0, 0, 0) of the sphere which cuts the sphere along a great circle. Hence the required geodesics are the arcs of the great circles.

So that is this, so d phi by theta is given by a divided by sin theta under root sin square theta minus a square and which is further simplified as a cosec square theta divided by 1 minus a square, cos square Theta. So now you integrate this, so d phi by 1 and this a cosec square Theta upon 1 minus a square, cosec square theta, d theta. So when you integrate will get Phi equal to integrand of this.

Now to find out simplifying this, what you can do, you can write cos square Theta as 1 plus cot square Theta and you can write it and this is simple integral and here you can take a cot Theta as some variable and you can simplify this integral as minus sin inverse a cot theta upon under root 1 minus a square and plus a dash where a dash is integration constant. So here when you simplify this, so phi is equal to minus sin inverse, a cot theta upon under root 1 minus a square plus a dash. So you take a dash here and take the sin on both the sides, you will get a cot theta equal to under root 1 minus a square and let me write it here this is quite clumsy here.

(Refer Slide Time: 33:50)

$$\begin{aligned}
 c \cos \theta &= A \sin \phi \sin \theta + B \cos \phi \sin \theta \\
 z &= Ay + Bx \\
 b &= c \sqrt{1 + \sin^2 \phi} \\
 f &= f(\theta, \phi, \phi') \\
 \frac{\partial f}{\partial \phi} - \frac{d}{d\phi}(b\phi') &= 0 \\
 \Rightarrow b\phi' &= \text{constant} \\
 \phi &= -\sin^{-1} \left( \frac{a \cot \theta}{\sqrt{1-a^2}} \right) + a' \\
 \Rightarrow \sin(a' - \phi) &= \frac{a \cot \theta}{\sqrt{1-a^2}} \\
 \Rightarrow \sqrt{1-a^2} \sin(a' - \phi) &= a \cot \theta \Rightarrow \cot \theta = \frac{\sqrt{1-a^2} [\sin \phi \cos \phi' - (a \sin \phi)]}{a} \\
 \cot \theta &= \frac{A \sin \phi \cos \phi' + B \cos \phi \cos \phi'}{\sqrt{1-a^2} \sin \phi' - \sqrt{1-a^2} \cos \phi'}
 \end{aligned}$$

So let me write it here, this is your phi here equal to minus sin inverse a cot theta upon under root 1 minus a square and here we have a dash. You can write it here that it is a sin of you can take this as you take minus here and sin of a dash minus phi is equal to a, this is cot theta, this cot, this cot theta, you can take this as a cot, cot theta is under root 1 minus a square.

So here you can simplify this and you can multiply by 1 minus a square here also, 1 minus a square sin of a dash minus phi equal to a cot theta. So here many simplify using the formula sin of a, a minus b you can write it here you can take a also. So here you can write it cot of theta equal to you can write it some constant of sin of phi plus B of cos of phi.

In fact this is what, this you can simplify as a cot Theta is equal to under root 1 minus a square and you can write it here sin of a dash cos of phi minus cos of a dash, sorry, cos of a dash sin of phi, right? So here you can simply say that you can divide it by a also and you can write it here a and this, so here you cot theta and you can call this as your a, so a is nothing but under root 1 minus a square divided by a and your sin of a dash.

Similarly your B is nothing but under root 1 minus a square upon a into cos of a dash, is it okay. So your b is given by this, so by taking A and B these constants you can write it cot of theta is equal to A sin phi plus B cos phi and you if you simplify you can take cos of theta is equal to this a sin phi sin theta plus B cos theta, sin of theta and this is what, this is cos of phi.

So this is cos of phi and if you multiply both side C then this is what? This is your z here and this is your y here and this is your x here, there is something wrong here, yes this is x, right? So here we can say that it is z equal to Ay plus B of x. Here I have to look at here the coefficient of sin phi is a and if you look at this is interchanged, so your A is this and B is this so that you can simplify.

So it is just a constant A is given by minus under root 1 minus A square upon A, cos of A dash but anyway you can always write it cot of theta equal to A sin phi plus B cos phi where A and B are suitable constants and when you simplify your equation is coming out to be some z equal to Ay plus B of x.

(Refer Slide Time: 37:46)

$$\frac{d\phi}{d\theta} = \frac{a}{\sin\theta\sqrt{(\sin^2\theta - a^2)}} = \frac{a\csc^2\theta}{1 - a^2\csc^2\theta}$$

On integration, we obtain

$$\phi = \int \frac{a\csc^2\theta d\theta}{\sqrt{[(1 - a^2) - (a\cot\theta)^2]}} + a' = -\sin^{-1}\left\{\frac{a\cot\theta}{\sqrt{1 - a^2}}\right\} + a'$$

$$\cot\theta = A\cos\phi + B\sin\phi$$

$$c\cos\theta = Ac\sin\theta\cos\phi + Bc\sin\theta\sin\phi$$

$$z = Ax + By$$

This is a plane through the centre (0, 0, 0) of the sphere which cuts the sphere along a great circle. Hence the required geodesics are the arcs of the great circles.

So here in calculation if I look at here, sorry, cot of theta is equal to A cos plus B sn phi and when you multiply by C it is coming out to be Ac sin theta cos phi plus Bc sin theta sin phi and which is nothing but A plane passing through the origin 000, right? So we can say that the curve which minimises the extreme minimises the functional is basically a plane through the centre of this sphere and which cut the spear along a great circle.

So w here we can say that the required Geodesics are the arcs of the great circles, so here we stop here but before stopping here you can give 1 point on this example, you can simplify this and whether it is z equal to Ax plus By or it is given as Ay plus Bx but anyway it is a plane passing through the sphere. So here we stop and we will meet in next lecture where we can discuss the extremal or say Euler equation for in place of curve, it is the Euler equation for the sphere, okay.

So here we stop and we will meet in a next lecture, thank you for listening us, thank you.
