**Brachistochrone problem and Euler's equation-1**

Hello friends, welcome to my lecture on Brachistochrone problem and Euler's equations.

(Refer Slide Time: 0:27)

**Euler's equation:**  
A necessary condition for the functional

$$I = \int_{x_1}^{x_2} f(x, y, y') dx,$$

to be an extremum is that

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \left( \frac{\partial f}{\partial y'} \right) = 0$$

This is called **Euler's equation**.

IIIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 2

We know that a necessary condition for the functional  $I$  equal to integral  $x_1$  to  $x_2$   $f(x, y, y')$   $dx$  to be an extremum is that  $\frac{\partial f}{\partial y} - \frac{d}{dx} \left( \frac{\partial f}{\partial y'} \right) = 0$  and we call this equation as the Euler's equation.

(Refer Slide Time: 0:49)

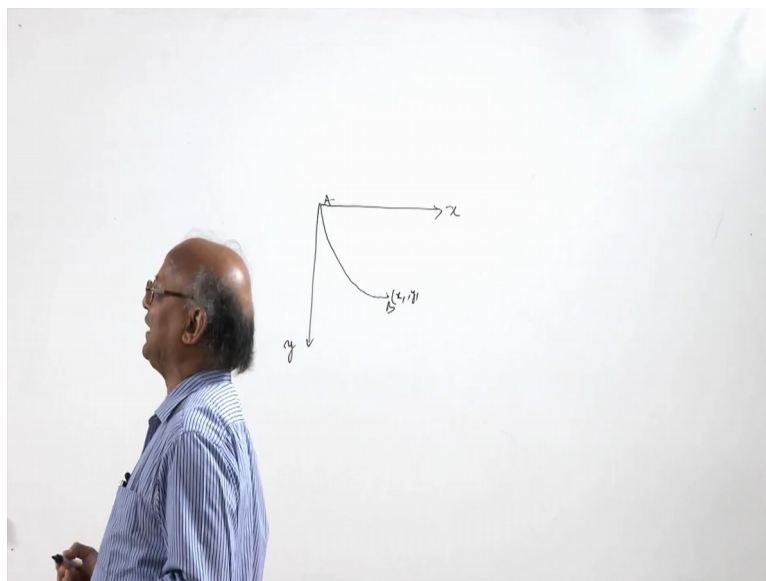

**Brachistochrone problem:**  
This problem derives its name from the Greek words '**brachistos**' meaning **shortest** and '**chronos**' meaning **time**.

This problem was proposed by John Bernoulli in 1696 and its solution formed the basis for the study of the calculus of variations. Here we find the path traversed by a particle sliding from a given point **A** to another point **B** in the shortest time under the action of gravity (friction and resistance of the medium are ignored).

IIIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 3

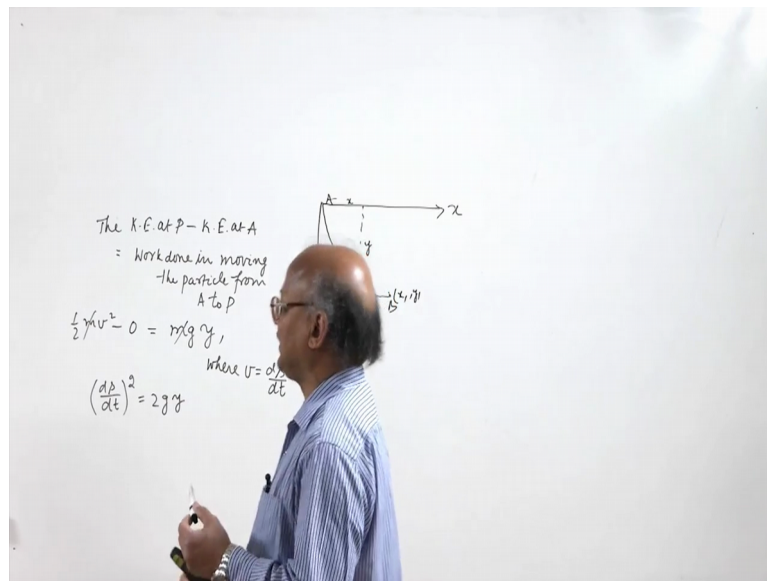

(The) this problem which we are going to discuss now this brachistochrone problem derives its name from the greek words brachistos and brachistos means shortest and chromos means time. So brachistochrone problem actually discusses the shortest time that a particle will take and sliding down from 1 point to the other. This problem was proposed by John Bernoulli in 1696 and its solution formed the basis of the study of calculus of variations. Now here we shall find the path traversed by a particle which slides from a given point A to another point B in the shortest time under the action of gravity. We shall assume that the friction and resistance of the of the medium are ignored.

(Refer Slide Time: 1:38)

So let us say let say the point A be at the origin, the y axis is pointed downwards and this our x-axis. So let A be the origin, y be measured downwards and B be the point at  $(x_1, y_1)$ . Let say this is the point  $(x_1, y_1)$ . The particle slides down from the point A to the point B in time let us say  $t$ .

(Refer Slide Time: 2:12)

Let  $A$  be the origin  $(0,0)$  and  $y$  be measured downwards. Let  $B$  be the point  $(x_1, y_1)$ . We assume that the particle starts sliding along the curve  $AB$  from  $A$  with the zero velocity.

Let at any time  $t$ , the arc  $AP=s$ .

Then, by the principle of conservation of energy

Kinetic energy at  $P$  - Kinetic energy at  $A$  = work done in moving the particle from  $A$  to  $P$ .

$$\frac{1}{2}mv^2 - 0 = mgy$$

$$\Rightarrow \frac{ds}{dt} = \sqrt{2gy}.$$

4

So then we assume that the particle starts sliding from the point  $A$  along the curve  $AB$  with the  $0$  velocity and let us say take any arbitrary point  $P$  on its path, so the coordinates of  $P$  are let us say  $x, y$  then  $y$  is this vertical height and this is  $x$ . So by the principle of conservation of energy the kinetic energy at  $p$  will be equal to the minus kinetic energy at  $A$  will be equals to work done in the moving the particle from  $A$  to  $P$ .

Now if  $V$  is the velocity of the particle then the kinetic energy at the point  $P$  let us say, the velocity of the particle be  $V$ . So then half  $mV$  square minus, it starts at the point  $A$  with  $0$  velocity. So the kinetic energy there at the point  $A$  is  $0$ . So minus  $0$  equal to  $mg y$  by the height vertical height of the point  $P$ . Now this  $B$  is equal to  $ds$  by  $dt$ . So what do we have? We

can cancel m and then we have ds by dt whole square equal to 2gy or we can say ds by dt is equal to under root 2gy.

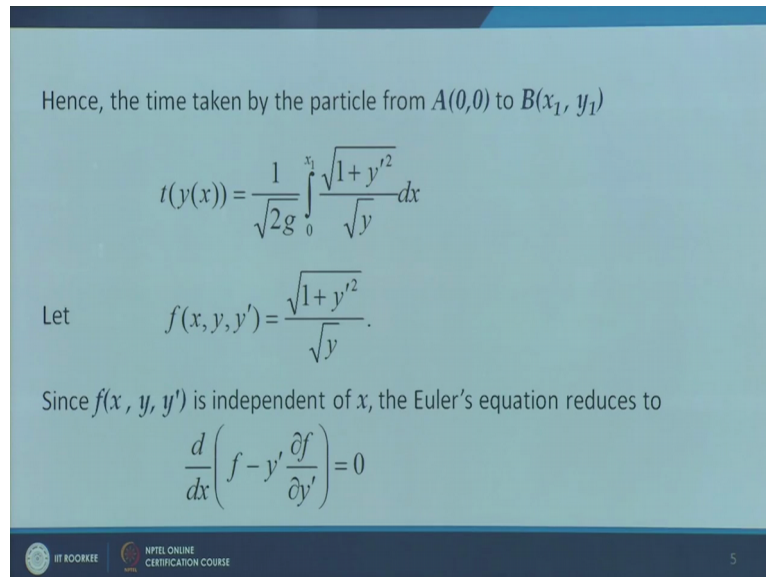

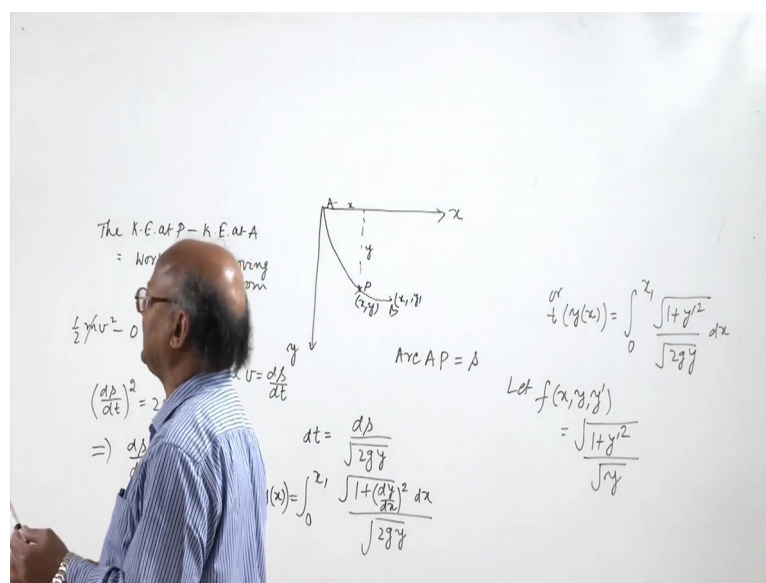

(Refer Slide Time: 4:02)

Hence, the time taken by the particle from A(0,0) to B(x<sub>1</sub>, y<sub>1</sub>)

$$t(y(x)) = \frac{1}{\sqrt{2g}} \int_0^{x_1} \frac{\sqrt{1+y'^2}}{\sqrt{y}} dx$$

Let  $f(x, y, y') = \frac{\sqrt{1+y'^2}}{\sqrt{y}}$ .

Since  $f(x, y, y')$  is independent of x, the Euler's equation reduces to

$$\frac{d}{dx} \left( f - y' \frac{\partial f}{\partial y'} \right) = 0$$

Now let us say t is the time taken by the particle from sliding from A to the point B whose coordinates we have taken as (x<sub>1</sub>, y<sub>1</sub>) then t will be a function of y okay, y will depend on X and we shall have from there if you take the square root ds by dt will be equal to under root 2gy, where (( ))(4:29) we have taken a positive sign here, because as t increases s also increases, the arc AP is s.

Now subtract the variables, so we have dt equal to ds upon under root 2gy when we integrate from 0 to from A equal to 0 to the point P, we shall have 0 to t is y(x) will be equal to 0 to x<sub>1</sub> and then ds is equal to under root 1 plus dy by dx whole square into dx divided by under root

$\frac{1}{\sqrt{2g}}$  or we can write it as. So we can write  $t(y(x))$  equal to  $\frac{1}{\sqrt{2g}}$  which is a constant we can take it outside the integral. So  $\frac{1}{\sqrt{2g}}$  integral from 0 to  $x_1$  of  $\frac{\sqrt{1+y'^2}}{\sqrt{y}}$  and let us now assume that  $f(x, y, y')$  be equal to  $\frac{\sqrt{1+y'^2}}{\sqrt{y}}$ . So let us say,  $\frac{1}{\sqrt{2g}}$  is a constant so it does not play any role in determining the extremum value of this integral. So we have taken it outside.

(Refer Slide Time: 6:39)

Hence, the time taken by the particle from  $A(0,0)$  to  $B(x_1, y_1)$

$$t(y(x)) = \frac{1}{\sqrt{2g}} \int_0^{x_1} \frac{\sqrt{1+y'^2}}{\sqrt{y}} dx$$

Let  $f(x, y, y') = \frac{\sqrt{1+y'^2}}{\sqrt{y}}$ .

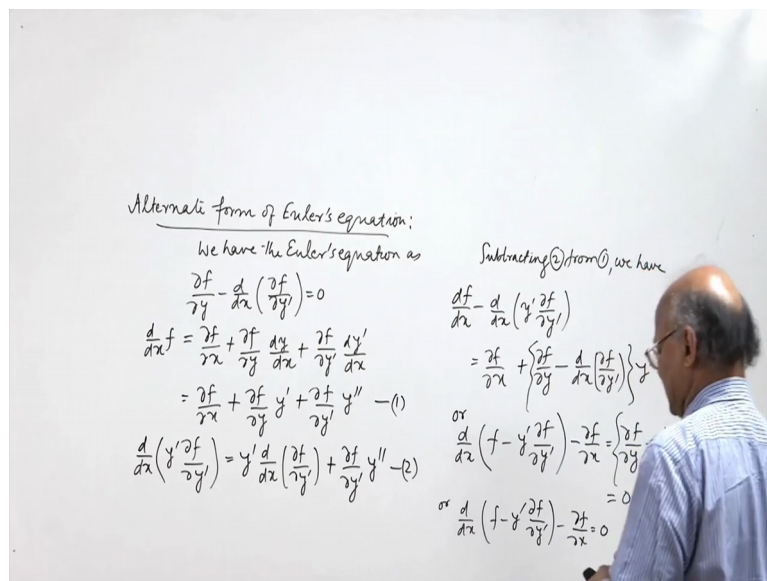

Since  $f(x, y, y')$  is independent of  $x$ , the Euler's equation reduces to

$$\frac{d}{dx} \left( f - y' \frac{\partial f}{\partial y'} \right) = 0$$

5

And now let us recall that if the function  $f(x, y, y')$  is independent of  $x$  then the Euler's equation is given by this alternate form. The Euler's equation gives and reduces to  $\frac{d}{dx} \left( f - y' \frac{\partial f}{\partial y'} \right) = 0$ . Here you can see that  $f(x, y, y')$  depends only on  $y$  and  $y'$  it does not depend on  $x$ . So the Euler's equation reduces to this.

(Refer Slide Time: 7:24)

And the proof of this is a we alternate form of with an easily do this alternate form of we have the Euler's equation as. This is the Euler's equation. Now let us find its alternate form. let us find first d over dx of f. Now f is the function of x, y and y dash. So I can write it as delta f by delta x delta f by delta y into dy by dx plus delta f by delta y dash dy dash by dx or I can write it as like this and then let us find d over dx of y dash into partial derivative of f with respect to y dash then what we will get y dash times d over dx of plus into y double dash. Let us call this as equation 1 and this as equation 2. So when you subtract the equation 2 from 1. So subtracting 2 from 1 we have, df by dx minus d over dx of y dash delta f by delta y dash.

Now what will happen when we subtract 2 from 1? This term this term delta f by delta y dash y double dash will cancel with delta f over delta y dash y double dash and what we will get delta f by delta x plus delta f by delta y minus d over dx of delta f by delta y dash into y dash or we can say I can write it as d over dx of f minus y dash delta f by delta y dash that is the left hand side minus delta f by delta x equal to delta f by delta y minus d over dx of delta f by delta y dash into y dash.

Now from the Euler's equation we know that this is 0 delta f by delta y minus d over dx delta f over delta y dash is equal to 0. So right hand side is equal to 0 and thus we get (the) or I can say d over dx of f minus y dash delta f by delta y dash minus delta f by delta x equal to 0. So this is another form of the Euler's equation and in case f is independent of x, it reduces to d over dx f minus y dash delta f over delta y dash equal to 0 like here.

(Refer Slide Time: 11:44)

Hence, the time taken by the particle from  $A(0,0)$  to  $B(x_1, y_1)$

$$t(y(x)) = \frac{1}{\sqrt{2g}} \int_0^{x_1} \frac{\sqrt{1+y'^2}}{\sqrt{y}} dx$$

Let  $f(x, y, y') = \frac{\sqrt{1+y'^2}}{\sqrt{y}}$ .

Since  $f(x, y, y')$  is independent of  $x$ , the Euler's equation reduces to

$$\frac{d}{dx} \left( f - y' \frac{\partial f}{\partial y'} \right) = 0$$

 5

Here,  $f$  is a function of  $y$  and  $y'$  only. It does not depend on  $x$ . So the Euler's equation this one reduces to this equation. Now from here when we integrate with respect to  $x$  we will have  $f$  minus  $y'$  delta  $f$  over delta  $y'$  is equal to some constant.

(Refer Slide Time: 12:01)

$$\Rightarrow f - y' \frac{\partial f}{\partial y'} = c, \text{ (say)}$$

or  $(1+y'^2)^{1/2} - y'^2(1+y'^2)^{-1/2} = c\sqrt{y}$

or  $\frac{dy}{dx} = \sqrt{\frac{c_1 - y}{y}}$

on integrating, we get

$$\int_0^x dx = \int_0^x \sqrt{\frac{y}{c_1 - y}} dy$$

 6

So this is what we have  $f$  minus  $y'$  delta  $f$  over delta  $y'$  is equal to  $C$ .

(Refer slide time: 12:31)

Hence, the time taken by the particle from  $A(0,0)$  to  $B(x_1, y_1)$

$$t(y(x)) = \frac{1}{\sqrt{2g}} \int_0^{x_1} \frac{\sqrt{1+y'^2}}{\sqrt{y}} dx$$

Let  $f(x, y, y') = \frac{\sqrt{1+y'^2}}{\sqrt{y}}$ .

Since  $f(x, y, y')$  is independent of  $x$ , the Euler's equation reduces to

$$\frac{d}{dx} \left( f - y' \frac{\partial f}{\partial y'} \right) = 0$$

5

$$\Rightarrow f - y' \frac{\partial f}{\partial y'} = c, \text{ (say)}$$

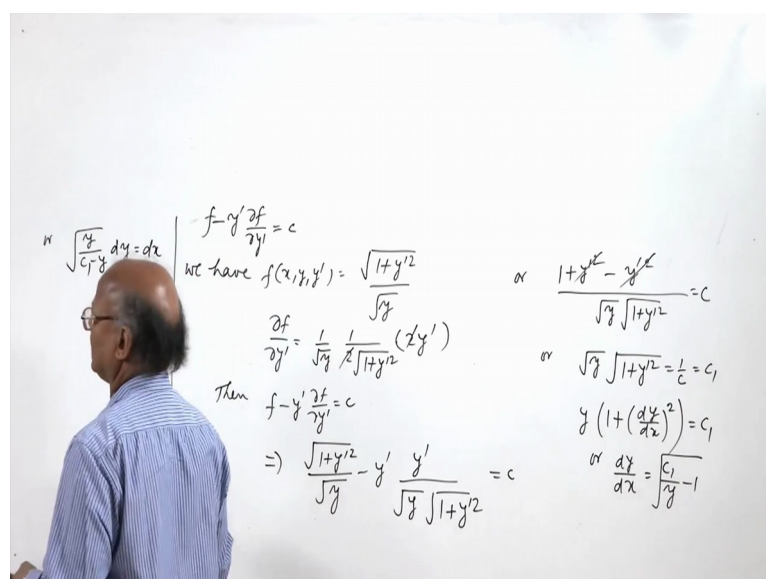

or  $(1+y'^2)^{1/2} - y'^2(1+y'^2)^{-1/2} = c\sqrt{y}$

or  $\frac{dy}{dx} = \sqrt{\frac{c_1 - y}{y}}$

on integrating, we get

$$\int_0^x dx = \int_0^x \sqrt{\frac{y}{c_1 - y}} dy$$

6

$\int \frac{y'}{\sqrt{c_1 - y}} dy = dx$

$f - y' \frac{\partial f}{\partial y'} = c$

we have  $f(x, y, y') = \frac{\sqrt{1+y'^2}}{\sqrt{y}}$

$\frac{\partial f}{\partial y'} = \frac{1}{\sqrt{y}} \cdot \frac{1}{\sqrt{1+y'^2}} (2y')$

Then  $f - y' \frac{\partial f}{\partial y'} = c$

$\Rightarrow \frac{\sqrt{1+y'^2}}{\sqrt{y}} - y' \frac{y'}{\sqrt{y} \sqrt{1+y'^2}} = c$

$\alpha \frac{1+y'^2 - y'^2}{\sqrt{y} \sqrt{1+y'^2}} = c$

$\alpha \frac{1}{\sqrt{y} \sqrt{1+y'^2}} = c$

$\alpha \sqrt{y} \sqrt{1+y'^2} = \frac{1}{c} = c_1$

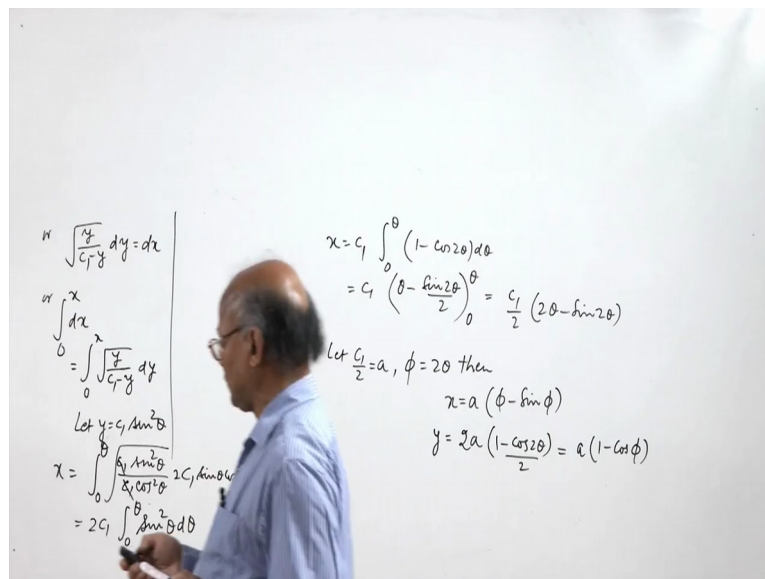

$y \left( 1 + \left( \frac{dy}{dx} \right)^2 \right) = c_1^2$

$\alpha \frac{dx}{dy} = \sqrt{\frac{c_1^2}{y} - 1}$

Now  $f$  is equal to Euler's simplify this equation  $f$  minus  $y$  dash we have  $f$  equal to under root 1 plus  $y$  dash square upon root  $y$ . So we find the partial derivative with respect to  $y$  dash from here. So we shall have 1 over root  $y$  1 over 2 square root under root 1 plus  $y$  dash square into  $2y$  dash. So this 2 will cancel with this 2 here and then  $f$  minus  $y$  dash  $\Delta f$  over  $\Delta y$  dash is equal to  $C$  gives us under root 1 plus  $y$  dash square divided by root  $y$  minus  $y$  dash times  $y$  dash divided by root  $y$  into under root 1 plus  $y$  dash square equal to  $C$ .

So what we will get? Root  $y$  into square root 1 plus  $y$  dash square and then we shall have 1 plus  $y$  dash square minus  $y$  dash square equal to  $C$ . So this cancel's and we get or under root  $y$  into  $y$  dash, under root 1 plus  $y$  dash square equal to 1 by  $C$ . So what we get is we can solve it. So let us see, this is  $y$  times 1 plus  $dy$  by  $dx$  whole square 1 over  $C$  if we put as  $C1$  so then this is  $C1$ . So or we can say  $dy$  by  $dx$  is equal to  $C1$  over  $y$  minus 1 square root. Now as  $x$  increases  $y$  also increases. So we get this so  $C1$  this is so the subtracting the variables we will get or root  $y$  over  $C1$  minus  $y$  or into  $dy$  is equal to  $dx$ .

(Refer Slide time: 15:42)

So let us integrate with respect to let us integrate both sides. So integral this will give you integral 0 to  $x$   $dx$  equal to integral 0 to  $x$ . So let us now put let  $y$  be equal to  $C1 \sin$  square theta. So left hand side becomes  $x$  and we get here 0 to  $dy$  will become  $2C1 \sin$  theta  $\cos$  theta  $d\theta$  and this is one  $x$  is  $x$   $y$  is  $y$ , so I think we should put here  $y$  here. So this will give you 0 to  $\pi$  by 2 and or we can say 0 to theta not  $\pi$  by 2 at this point 0, it should be theta not 0 not  $\pi$  by 2, it should be theta. So this  $x$  here, let me write  $x$  here. So this is  $C1 \sin$  square theta and what we will get  $C1$  minus  $C1 \sin$  square theta  $C1 \cos$  square theta,  $dy$  is  $2C1 \sin$  theta  $\cos$  theta  $d\theta$ , we have to put the limit for theta. So we have written it theta.

So this is  $C1$  cancel out here and what we will get here,  $2C1 \int_0^\theta \cos \theta \sin^2 \theta \, d\theta$  and then we shall have  $\cos \theta$  will cancel with  $\cos \theta$  we shall have  $\sin^2 \theta \, d\theta$ . So what we have is this. so this is now we can integrate this. So this is  $x$  equal to  $C1 \int_0^\theta (1 - \cos 2\theta) \, d\theta$ . So this is equal to  $C1$  then we have  $\theta - \frac{\sin 2\theta}{2}$ , the integral of  $1 - \cos 2\theta$ . So  $0$  to  $\theta$  will give you  $C1$  by  $2$   $2\theta - \sin 2\theta$ . Now let us say, let  $C1$  by  $2$  equal to  $a$  and  $\phi$  be equal to  $2\theta$  then,  $x$  is equal to  $a$  times  $\phi - \sin \phi$  and  $y$  is equal to  $C1 \sin^2 \theta$ . So  $y$  is equal to  $C1$ ,  $C1$  is equal to  $2a$  and  $\sin^2 \theta$  is  $1 - \cos 2\theta$  divided by  $2$ . So this will be  $a$  times  $1 - \cos \phi$ .

(Refer Slide Time: 19:07)

Solving, we get

$$x = a(\phi - \sin \phi), \quad y = a(1 - \cos \phi)$$

which is a cycloid.

The constant 'a' is determined from the fact that the curve passes through  $(x_1, y_1)$ .

Thus, the path of the particle is a cycloid.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

So  $x$  equal to  $a$  times  $\phi - \sin \phi$ ,  $y$  equal to  $a$  times  $1 - \cos \phi$  and it is very well known that the parametric equations of the cycloid are given by  $x$  equal to  $a$  times  $\phi - \sin \phi$ ,  $y$  equal to  $a$  times  $1 - \cos \phi$ . So when the path key (19:20) slides under the action of gravity where the resistance and the friction of the medium are neglected, it travels along the satellite. Its path is that of a cycloid. The constant here is determined from the fact that the particle passes through the point  $(x_1, y_1)$ . So that will give you the values of  $a$  and  $\phi$ .

(Refer Slide Time: 20:04)

**Euler's equation in the case of several dependent variables:**

We extend the variational problem for the case of one variable i.e.  $\int_{x_1}^{x_2} f(x, y, y') dx$  to the case of the several variables as functions of a single independent variable i.e. a necessary condition for the functional

$$\int_{x_1}^{x_2} f(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n') dx, \quad y_i = y_i(x), \quad i = 1, 2, \dots, n$$

to be an extremum is that

$$\frac{\partial f}{\partial y_i} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_i'} \right) = 0, \quad i = 1, 2, \dots, n.$$

8

Now let us show the path of the particle is a cycloid. Now let us consider Euler's equation in the case of several dependent variables, you have earlier done the Euler's equation in the case of one dependent variable. Now we shall be doing the Euler's equation in the case of several dependent variables. So in previous lectures you have studied how to find the extremum value of this functional, where there is one independent variable  $x$  and there is one dependent variable  $y$ . So we discuss the case of the Euler's equation in the case of 1 dependent variable. Now we shall extend the study to the case of several dependent variables. So the variational problem will be now extended to the case of several variables as function of a single independent variable.

let us consider for example, this functional integral  $x_1$  to  $x_2$   $f(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n')$   $dx$  this functional we want to extremize this functional where  $y_i$  is our dependent variables, which are depend on the one single independent variable  $x$  and  $i$  varies from 1 to  $n$ . So there are  $n$  independent variables all depending on 1 single independent variable  $x$  and the condition for this functional to be an extremum is that the partial derivative of  $f$  with respect to  $y_i$ ,  $y_i$  is  $i$ th dependent variable, minus  $d$  over  $dx$  partial derivative of  $f$  with respect to  $y_i'$  is equal to 0 and this must hold for all values of  $i$ ,  $i$  equal to 1 to  $n$ . So there will be system of  $n$  equations here corresponding to the  $n$  dependent variables  $y_i$ .

(Refer Slide Time: 21:36)

**Proof:**

Let us consider the functional

$$I = \int_{x_1}^{x_2} f(x, y_1, y_2, y_1', y_2') dx. \quad \dots(1)$$

We wish to find necessary conditions to be satisfied by the two functions  $y_1(x)$  and  $y_2(x)$  that extremize the functional  $I$ .

Let us suppose that  $y_1(x)$  and  $y_2(x)$  satisfy the boundary conditions  $y_i(x_1) = y_{i1}$ ,  $y_i(x_2) = y_{i2}$ , for  $i = 1, 2$  i.e.  $y_1(x_1) = y_{11}$ ,  $y_1(x_2) = y_{12}$  and  $y_2(x_1) = y_{21}$ ,  $y_2(x_2) = y_{22}$ .

**Euler's equation in the case of several dependent variables:**

We extend the variational problem for the case of one variable i.e.  $\int_{x_1}^{x_2} f(x, y, y') dx$  to the case of the several variables as functions of a single independent variable i.e. a necessary condition for the functional

$$\int_{x_1}^{x_2} f(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n') dx, \quad y_i = y_i(x), \quad i = 1, 2, \dots, n$$

to be an extremum is that

$$\frac{\partial f}{\partial y_i} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_i'} \right) = 0, \quad i = 1, 2, \dots, n.$$

Now let us we shall prove this result we shall find this necessary condition for this functional for the case  $n$  equal to 2. The proof can be really extended to the case of any arbitrary  $n$ .

(Refer Slide Time: 22:00)

**Proof:**  
Let us consider the functional

$$I = \int_{x_1}^{x_2} f(x, y_1, y_2, y_1', y_2') dx. \quad \dots(1)$$

We wish to find necessary conditions to be satisfied by the two functions  $y_1(x)$  and  $y_2(x)$  that extremize the functional  $I$ .  
Let us suppose that  $y_1(x)$  and  $y_2(x)$  satisfy the boundary conditions  $y_i(x_1) = y_{i1}$ ,  $y_i(x_2) = y_{i2}$ , for  $i = 1, 2$  i.e.  $y_1(x_1) = y_{11}$ ,  $y_1(x_2) = y_{12}$  and  $y_2(x_1) = y_{21}$ ,  $y_2(x_2) = y_{22}$ .

9

Now let us consider this functional  $I$  equal to  $x_1$  to  $x_2$   $f(x, y, y_2, y_1 \text{ dash}, y_2 \text{ dash})$ . Now we (( ))(21:56) to find the necessary condition to be satisfied by the two functions  $y_1$  and  $y_2$ , which depend on the single independent variable  $x$  and those values of  $y_1, y_2$  which extremize this functional  $I$ . So now suppose that  $y_1$  and  $y_2$   $x$  satisfy the boundary conditions at the point  $x_1$  by  $y_1$   $x_1$  is equal to  $y$  is equal  $11$  and  $y_1$  at  $x_2$  is takes the value  $y_{12}$   $y_2$  function at  $x_1$  takes the value  $y_{21}$  and  $y_2$  at  $x_2$  takes the value  $y_{22}$ .

(Refer Slide Time: 22:30)

**Proof:**  
Let us consider the functional

$$I = \int_{x_1}^{x_2} f(x, y_1, y_2, y_1', y_2') dx. \quad \dots(1)$$

We wish to find necessary conditions to be satisfied by the two functions  $y_1(x)$  and  $y_2(x)$  that extremize the functional  $I$ .  
Let us suppose that  $y_1(x)$  and  $y_2(x)$  satisfy the boundary conditions  $y_i(x_1) = y_{i1}$ ,  $y_i(x_2) = y_{i2}$ , for  $i = 1, 2$  i.e.  $y_1(x_1) = y_{11}$ ,  $y_1(x_2) = y_{12}$  and  $y_2(x_1) = y_{21}$ ,  $y_2(x_2) = y_{22}$ .

9

Now, let us consider two arbitrary functions say  $\eta_1(x)$  and  $\eta_2(x)$  which are all zero on the boundary i.e.  $\eta_1(x_1) = \eta_1(x_2) = \eta_2(x_1) = \eta_2(x_2) = 0$ .

Replacing  $y_1$  and  $y_2$  by  $y_1 + \varepsilon_1 \eta_1$  and  $y_2 + \varepsilon_2 \eta_2$  in (1), we get

$$I(\varepsilon_1, \varepsilon_2) = \int_{x_1}^{x_2} f(x, y_1 + \varepsilon_1 \eta_1, y_2 + \varepsilon_2 \eta_2, y_1' + \varepsilon_1 \eta_1', y_2' + \varepsilon_2 \eta_2') dx. \quad \dots(2)$$

Then  $I$  is a function of the parameters  $\varepsilon_1$  and  $\varepsilon_2$  and reduces to (1) when  $\varepsilon_1 = \varepsilon_2 = 0$ .

Let us consider 2a arbitrary functions  $\eta_1(x)$  and  $\eta_2(x)$ , which assume value 0 at the boundary points  $\eta_1$  at  $x_1$  and  $\eta_1$  at  $x_2$  is equal to 0. Similarly  $\eta_2$  at  $x_1$  and  $\eta_2$  at  $x_2$  is equal to 0. Now what we will do is? In the given functional we shall replace  $y_1$  and  $y_2$  by  $y_1$  plus  $\varepsilon_1 \eta_1$  and  $y_2$  by  $y_2$  plus  $\varepsilon_2 \eta_2$ , then the functional that we get will be a function of  $\varepsilon_1$  and  $\varepsilon_2$ , we shall call it as  $I(\varepsilon_1, \varepsilon_2)$ . So the function will take the form  $x_1$  to  $x_2$   $f(x, y_1 + \varepsilon_1 \eta_1, y_2 + \varepsilon_2 \eta_2, y_1' + \varepsilon_1 \eta_1', y_2' + \varepsilon_2 \eta_2')$  and then  $y_1$  dash plus  $\varepsilon_1 \eta_1$  dash  $y_2$  dash  $\varepsilon_2 \eta_2$  dash. Now this  $I$  then is a function of 2 parameters  $\varepsilon_1$  and  $\varepsilon_2$  and it we you can see that it reduces to the previous given functional this the this one, when  $\varepsilon_1 \varepsilon_2$  take value 0s.

(Refer Slide Time: 23:35)

Now, let us consider two arbitrary functions say  $\eta_1(x)$  and  $\eta_2(x)$  which are all zero on the boundary i.e.  $\eta_1(x_1) = \eta_1(x_2) = \eta_2(x_1) = \eta_2(x_2) = 0$ .

Replacing  $y_1$  and  $y_2$  by  $y_1 + \varepsilon_1 \eta_1$  and  $y_2 + \varepsilon_2 \eta_2$  in (1), we get

$$I(\varepsilon_1, \varepsilon_2) = \int_{x_1}^{x_2} f(x, y_1 + \varepsilon_1 \eta_1, y_2 + \varepsilon_2 \eta_2, y_1' + \varepsilon_1 \eta_1', y_2' + \varepsilon_2 \eta_2') dx. \quad \dots(2)$$

Then  $I$  is a function of the parameters  $\varepsilon_1$  and  $\varepsilon_2$  and reduces to (1) when  $\varepsilon_1 = \varepsilon_2 = 0$ .

To find the stationary value of (1), we find the stationary value of  $I(\varepsilon_1, \varepsilon_2)$  for  $\varepsilon_1 = \varepsilon_2 = 0$ .

$I(\varepsilon_1, \varepsilon_2)$  will be extremum when

$$\frac{\partial I}{\partial \varepsilon_1} = 0, \quad \frac{\partial I}{\partial \varepsilon_2} = 0.$$

Using the Leibnitz rule of differentiation under the integral sign

$$\frac{\partial I}{\partial \varepsilon_1} = \int_{x_1}^{x_2} \frac{\partial}{\partial \varepsilon_1} f(x, y_1 + \varepsilon_1 \eta_1, y_2 + \varepsilon_2 \eta_2, y_1' + \varepsilon_1 \eta_1', y_2' + \varepsilon_2 \eta_2') dx.$$

Now to find the stationary value of this function, since  $I$  is a function of 2 variables  $\varepsilon_1$  and  $\varepsilon_2$ , it will assume extremum value provided its partial derivative with respect to  $\varepsilon_1$  and  $\varepsilon_2$  are 0 that is those are the necessary conditions for  $I$  to have an extremum value. Now when we differentiate  $I$  with respect to  $\varepsilon_1$  let us see how what we get.

(Refer Slide Time: 24:04)

Now, let us consider two arbitrary functions say  $\eta_1(x)$  and  $\eta_2(x)$  which are all zero on the boundary i.e.  $\eta_1(x_1) = \eta_1(x_2) = \eta_2(x_1) = \eta_2(x_2) = 0$ .

Replacing  $y_1$  and  $y_2$  by  $y_1 + \varepsilon_1 \eta_1$  and  $y_2 + \varepsilon_2 \eta_2$  in (1), we get

$$I(\varepsilon_1, \varepsilon_2) = \int_{x_1}^{x_2} f(x, y_1 + \varepsilon_1 \eta_1, y_2 + \varepsilon_2 \eta_2, y_1' + \varepsilon_1 \eta_1', y_2' + \varepsilon_2 \eta_2') dx. \quad \dots(2)$$

Then  $I$  is a function of the parameters  $\varepsilon_1$  and  $\varepsilon_2$  and reduces to (1) when  $\varepsilon_1 = \varepsilon_2 = 0$ .

To find the stationary value of (1), we find the stationary value of  $I(\varepsilon_1, \varepsilon_2)$  for  $\varepsilon_1 = \varepsilon_2 = 0$ .

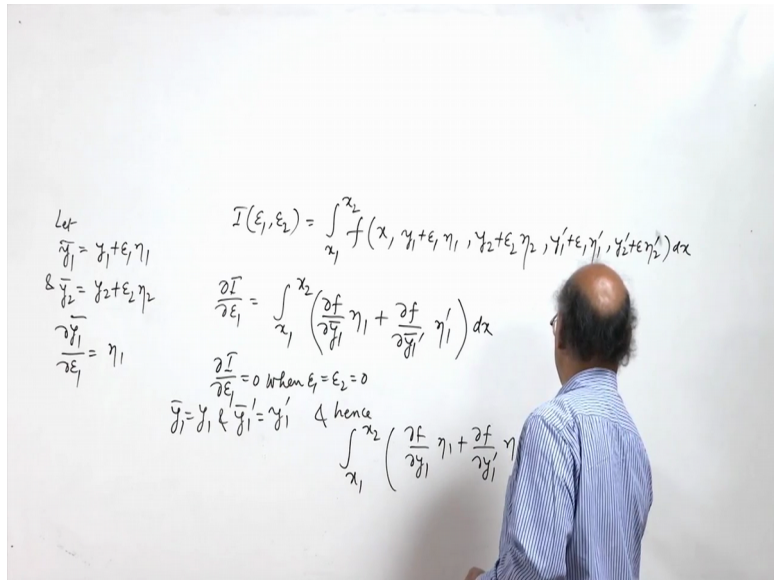

$I(\varepsilon_1, \varepsilon_2)$  will be extremum when

$$\frac{\partial I}{\partial \varepsilon_1} = 0, \quad \frac{\partial I}{\partial \varepsilon_2} = 0.$$

Using the Leibnitz rule of differentiation under the integral sign

$$\frac{\partial I}{\partial \varepsilon_1} = \int_{x_1}^{x_2} \frac{\partial}{\partial \varepsilon_1} f(x, y_1 + \varepsilon_1 \eta_1, y_2 + \varepsilon_2 \eta_2, y_1' + \varepsilon_1 \eta_1', y_2' + \varepsilon_2 \eta_2') dx.$$

11

So this is I, when we differentiated with respect to x with respect to epsilon1. Since the integrand is a function of I1 epsilon1, so we will have to use the (( ))(25:05) of differentiation under the integral sign and here the limits of integration are constant. So we shall have x1 to x2. Now let us say that y1 bar be equal to y1 plus epsilon1 eta1 and y2 bar be equal to y2 plus epsilon2 eta2, okay. Then since the limits of integration do not depend on x1 and x2 upon epsilon1 and epsilon2, the partial derivative of y with respect epsilon1 will be x1 to x2, the partial derivative of this integrand with respect to epsilon1 and when we differentiated with respect to epsilon1, we shall have, so delta f over delta y bar delta y bar y1 bar and delta y1 bar over delta y1 bar over delta epsilon1 will be equal to eta1. So we shall have eta1 and then delta y1 f over delta y1 bar dash into epsilon1 dash.

When we differentiate it partially with respect to epsilon1, the this will be differentiated with respect to epsilon1. This is y1 bar, this is y1 bar dash. So partial derivative of f with respect to y1 bar into partial derivative of y1 bar with respect to epsilon1, which is eta1. Partial derivative of f with respect to y1 bar dash. So this is this and then partial derivative y1 bar dash with respect to epsilon1 will be eta1 dash dx. So this is what we have. Now we have delta I over delta epsilon1 is equal to 0 when epsilon1 is equal to epsilon2 equal to 0. So when epsilon1, epsilon2 are 0s, y1 bar becomes y1 bar becomes y1 and y1 bar dash becomes y1 dash and hence, we have integral x1 to x2 delta f over delta y1 eta1 plus delta f over delta y1 dash eta1 dash dx equal to 0.

(Refer Slide Time: 28:20)

Hence  $\frac{\partial I}{\partial \varepsilon_1} = 0$  when  $\varepsilon_1 = \varepsilon_2 = 0$

$$\Rightarrow \int_{x_1}^{x_2} \left( \frac{\partial f}{\partial y_1} \eta_1 + \frac{\partial f}{\partial y_1'} \eta_1' \right) dx = 0 \quad \dots(3)$$

Now, integrating by parts, we have

$$\int_{x_1}^{x_2} \frac{\partial f}{\partial y_1'} \eta_1' dx = - \int_{x_1}^{x_2} \frac{d}{dx} \left( \frac{df}{dy_1'} \right) \eta_1(x) dx$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So we have this equation integral x1 to x2 delta f over delta y1 eta1 plus delta f over delta y1 dash eta1 dash dx equal to 0. Now let us integrate by parts. The second term of this on the left hand side.

(Refer Slide Time: 28:30)

$$\int_{x_1}^{x_2} \left( \frac{\partial f}{\partial y_1'} \eta_1' \right) dx$$

$$= \left\{ \frac{\partial f}{\partial y_1'} \eta_1(x) \right\}_{x_1}^{x_2} - \int_{x_1}^{x_2} \frac{d}{dx} \left( \frac{\partial f}{\partial y_1'} \right) \eta_1(x) dx$$

$$= 0 - \int_{x_1}^{x_2} \frac{d}{dx} \left( \frac{\partial f}{\partial y_1'} \right) \eta_1(x) dx$$

$\frac{\partial \mathcal{I}}{\partial \epsilon_1} = 0$  when  $\epsilon_1 = \epsilon_2 = 0$   
 $\bar{y}_1 = y_1$  &  $\bar{y}_1' = y_1'$  & hence

$$\int_{x_1}^{x_2} \left( \frac{\partial f}{\partial y_1} \eta_1 + \frac{\partial f}{\partial y_1'} \eta_1' \right) dx = 0$$

or

$$\int_{x_1}^{x_2} \left( \frac{\partial f}{\partial y_1} \eta_1 - \frac{d}{dx} \left( \frac{\partial f}{\partial y_1'} \right) \eta_1 \right) dx = 0$$

(So when we) so let us see, integral  $x_1$  to  $x_2$   $\delta f$  over  $\delta y_1$  dash  $\epsilon_1$  dash  $dx$ . When we integrated by parts, we have the partial derivative of  $f$  with respect to  $y_1$  dash into  $\epsilon_1 \eta_1(x)$   $x_1$  to  $x_2$  minus  $x_1$  to  $x_2$   $d$  over  $dx$  of this. Now we have assume that  $\epsilon_1 = 0$  (29:15) that  $x_1$  and  $x_2$ . So since  $\epsilon_1(x)$   $x_2$  is equal to 0  $\epsilon_1(x_1)$  is equal to 0, so we shall have 0 minus integral  $x_1$  to  $x_2$  and  $d$  over  $dx$  of. So the second integral here second term here second term here becomes this. So this be this gives us or  $x_1$  to  $x_2$   $\delta f$  over  $\delta y_1$   $\epsilon_1$  minus  $d$  over  $dx$  of we get this, okay. So thus we have integral  $x_1$  to  $x_2$   $\delta f$  over  $\delta y_1$  minus  $d$  over  $dx$   $\delta f$  over  $\delta y_1$  dash multiplied by the function  $\eta_1(x)$   $dx$  equal to 0. So this equation holds true for all choices of  $\eta_1(x)$ . Therefore, we must have  $\delta f$  over  $\delta y_1$  minus  $d$  over  $dx$  of  $\delta f$  over  $\delta y_1$  dash equal to 0.

(Refer Slide Time: 30:35)

(3)  $\Rightarrow \int_{x_1}^{x_2} \left\{ \frac{\partial f}{\partial y_1} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_1'} \right) \right\} \eta_1(x) dx = 0$  .

Since this equation must hold good for all choices of  $\eta_1(x)$ , we get

$$\frac{\partial f}{\partial y_1} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_1'} \right) = 0 \quad \dots(4)$$

Similarly  $\frac{\partial I}{\partial \varepsilon_2} = 0$ , when  $\varepsilon_1 = \varepsilon_2 = 0$ , implies

$$\frac{\partial f}{\partial y_2} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_2'} \right) = 0. \quad \dots(5)$$

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

Similarly when we differentiate I1 epsilon1, epsilon2 with respect to epsiln2 by using the ((  
(30:37) rule of differentiation under integral sign and put epsilon1 epsilon2 equal to 0 what  
we will get is delta f over delta y2 minus d over dx of delta f over delta y2 dash equal to 0.

(Refer Slide Time: 30:51)

Hence to find the extremals of our problem, we solve the equation (4) and (5).

Thus in general to find the extremals of the functional

$$I = \int_{x_1}^{x_2} f(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n') dx.$$

We have to solve the equations

$$\frac{\partial f}{\partial y_i} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_i'} \right) = 0, \quad i = 1, 2, \dots, n.$$

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

$$(3) \Rightarrow \int_{x_1}^{x_2} \left\{ \frac{\partial f}{\partial y_1} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_1'} \right) \right\} \eta_1(x) dx = 0 .$$

Since this equation must hold good for all choices of  $\eta_1(x)$ , we get

$$\frac{\partial f}{\partial y_1} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_1'} \right) = 0 \quad \dots(4)$$

Similarly  $\frac{\partial I}{\partial \varepsilon_2} = 0$ , when  $\varepsilon_1 = \varepsilon_2 = 0$ , implies

$$\frac{\partial f}{\partial y_2} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_2'} \right) = 0. \quad \dots(5)$$

13

And thus to find the extremum of our problem we solve the 2 equations, this is this equation and this equation. So corresponding to two dependent variables  $y_1$  and  $y_2$  which depends on  $x$  we have 2 equations here, which are to be solved.

(Refer Slide Time: 31:10)

Hence to find the extremals of our problem, we solve the equation (4) and (5).

Thus in general to find the extremals of the functional

$$I = \int_{x_1}^{x_2} f(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n') dx.$$

We have to solve the equations

$$\frac{\partial f}{\partial y_i} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_i'} \right) = 0, \quad i = 1, 2, \dots, n.$$

14

So these two equations we have to solve to find the extremum of the problem in the case when  $n$  is equal to 2. In the general case we can generalize it to  $n$  variables. So in the case on  $n$  variables when  $I$  is an integral from  $x_1$  to  $x_2$  of  $f(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n')$  dx, then similarly we can say we shall have to solve  $n$  equations,  $\frac{\partial f}{\partial y_i} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_i'} \right) = 0$ , where  $i$  runs from 1 to  $n$ , 1, 2, 3 and so on up to  $n$ . In our next lecture we shall take examples on this Euler's equation (in the) when the

number of dependent variables are several and they depend on a single independent variable.

So with this I would like to conclude my lecture. Thank you very much for your attention.
