**Variational Problem Involving a Conditional Extremum-2**

Hello friends welcome to today's lecture and in today's lecture we will continue our discussion.

(Refer Slide Time: 0:30)

The image shows a whiteboard with three mathematical expressions written in black ink. The first expression is an integral: 
$$I[y_1, \dots, y_n] = \int_{x_0}^{x_1} F(x, y_1, \dots, y_n, y_1', \dots, y_n') dx.$$
 The second expression is 
$$\Phi_1(x, y_1, \dots, y_n) = 0$$
 The third expression is 
$$\Phi_i(x, y_1, \dots, y_n, y_1', \dots, y_n') = 0 \quad i = 1, \dots, m, m < n.$$

In previous lecture we have considered the variational problem with constraint this. Now in today's class we extend our discussion when this constraint is not only this finite equation but set of equations here. So we have  $y_1$  dash to say  $y_n$  dash is equal to 0 here,  $i$  is from 1 to say  $m$ , here  $m$  is less than  $n$  and try to see that how to find out the extremal functions of this variational problem provided this constraints are given.

(Refer Slide Time: 1:14)

**Constraints of the form  $\phi(x, y_1, y_2, \dots, y_n, y'_1, y'_2, \dots, y'_n)$**

In the preceding section we examined the problem of investigating the functional for an extremum:

$$v = \int_{x_0}^{x_1} f(x, y_1, y_2, \dots, y_n, y'_1, y'_2, \dots, y'_n) dx; y_j(x_0) = y_{j0}, \quad y_j(x_1) = y_{j1} \quad j = 1, 2, \dots, n$$

given the finite constraints

$$\phi_i(x, y_1, y_2, \dots, y_n) = 0, \quad i = 1, 2, \dots, m.$$

Now, if the constraint equations are the differential equations

$$\phi_i(x, y_1, y_2, \dots, y_n, y'_1, y'_2, \dots, y'_n) = 0, \quad i = 1, 2, \dots, m.$$

2

So let us consider here. So as I pointed out in the preceding section we examined the problem of investigating the functional for an extremum  $v$  equal to  $\int_{x_0}^{x_1} f$  of  $x, y_1$  to  $y_n, y_1$  dash to  $y_n$  dash  $d$  of  $x$  satisfying the boundary condition given at the end  $x$  not and given at the end  $x_1$  as  $y_j$   $x$  not equal to  $y_{j0}$  and  $y_j$   $x_1$  is equal to  $y_{j1}$  for each  $j$  is equal to 1 to  $n$  and here in we have discussed that we have constraint given in this form  $\phi_i$   $x, y_1$  to  $y_n$  equal to 0,  $i$  is from 1 to  $m$ .

But now let us consider the constraint in place of finite constraint let us consider the set of differential equations. So here constraints are set of differential equation  $\phi_i$   $x, y_1$  to  $y_n, y_1$  dash to  $y_n$  dash equal to 0 for  $i$  equal to 1 to  $m$ , here  $m$  is strictly less than  $n$ .

(Refer Slide Time: 2:12)

This type of constraints are called are called nonholonomic. In this case, we will prove a conditional extremum of a functional  $v$  is achieved on the same curves on which is achieved an unconditional extremum of the functional

$$\bar{v} = \int_{x_0}^{x_1} \left[ F + \sum_{i=1}^m \lambda(x) \phi_i \right] dx = \int_{x_0}^{x_1} \bar{F} dx,$$

where

$$\bar{F} = F + \sum_{i=1}^m \lambda(x) \phi_i.$$

suppose that one of the functional determinants of order  $m$  is different from zero, say,

$$\frac{D(\phi_1, \phi_2, \dots, \phi_m)}{D(y'_1, y'_2, \dots, y'_m)} \neq 0.$$

This guarantees independence of the constraints.

3

## Constraints of the form $\phi(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n')$

In the preceding section we examined the problem of investigating the functional for an extremum:

$$v = \int_{x_0}^{x_1} f(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n') dx; \quad y_j(x_0) = y_{j0}, \quad y_j(x_1) = y_{j1} \quad j = 1, 2, \dots, n$$

given the finite constraints

$$\phi_i(x, y_1, y_2, \dots, y_n) = 0, \quad i = 1, 2, \dots, m.$$

Now, if the constraint equations are the differential equations

$$\phi_i(x, y_1, y_2, \dots, y_n, y_1', y_2', \dots, y_n') = 0, \quad i = 1, 2, \dots, m.$$

So this type of constraint are called nonholonomic and the constraint defined here are called holonomic. So this we call as holonomic constraint and this we call as nonholonomic constraint. So in this case we will prove a conditional extremum of a functional  $v$  is achieved on the same curve on which it is achieved an unconditional extremum of the functional here. So as we discussed in previous case we also show that the extremal conditional extremum of  $v$  achieved on conditional extremum of this  $v$  bar.

So here we defined a new function  $F$  bar as  $F$  plus  $i$  equal to 1 to  $m$  lambda  $x$  phi of  $i$  and here we assume that these phi  $i$  are independent to each other it means that we are assuming that Jacobian of phi 1 to phi  $m$  with respect to  $y_1$  dash to  $y_m$  dash is not equal to 0. So here we are relabeling our variable in the sense that this Jacobian of phi 1 to phi  $m$  with respect to  $y_1$  dash to  $y_m$  dash are nonzero and this also guarantees the independence of the constraint.

(Refer Slide Time: 3:42)

Let  $y_1, y_2, \dots, y_n$  be an arbitrary permissible system of functions that satisfies the constraint equations  $\phi_i = 0$  ( $i = 1, 2, \dots, m$ ). Vary the constraint equations

$$\sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j} \delta y_j + \sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j'} \delta y_j' = 0, \quad i = 1, 2, \dots, m$$

Multiply term by term each of the equations obtained by the (as yet) undetermined factor  $\lambda_i(x)$  and integrate from  $x_0$  to  $x_1$ ; this yields

$$\int_{x_0}^{x_1} \lambda_i(x) \sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j} \delta y_j dx + \int_{x_0}^{x_1} \lambda_i(x) \sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j'} \delta y_j' dx = 0$$

So here we try to proceed in a similar way as we proceeded in previous section here. So here let us take  $y_1$  to  $y_n$  be an arbitrary permissible system of function that satisfy the constraint equation  $\phi_i = 0$  for each  $i = 1$  to  $m$ . Now here we vary the constraint equation and we have this  $j = 1$  to  $n$   $\delta \phi_i$  by  $\delta y_j$  plus summation  $j = 1$  to  $n$   $\delta \phi_i$  by  $\delta y_j'$  equal to 0 for each  $i = 1$  to  $m$ .

If you remember in previous case this term is not coming so so this term was not there in previous discussion. So as we discussed there what we try to do here we multiply by say each term by  $\lambda_i$  and integrate from  $x_0$  to  $x_1$  and we have this  $x_0$  to  $x_1$   $\lambda_i$   $\sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j} \delta y_j dx$  plus  $x_0$  to  $x_1$   $\lambda_i$   $\sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j'} \delta y_j' dx$  equal to 0. So again we have then addition of this term. So here we simplify the second term by transferring the derivative on this term.

(Refer Slide Time: 5:02)

integrating each term of the second integral by parts and taking into consideration that  $\delta y_j' = (\delta y_j)'$  and  $(\delta y_j)_{x=x_0} = (\delta y_j)_{x=x_1} = 0$ , we will have

$$\int_{x_0}^{x_1} \sum_{j=1}^n \left[ \lambda_i(x) \frac{\partial \phi_i}{\partial y_j} \delta y_j - \frac{d}{dx} \left( \lambda_i(x) \frac{\partial \phi_i}{\partial y_j'} \right) \right] \delta y_j dx = 0. \quad (1)$$

From the basic necessary condition for an extremum,  $\delta v = 0$ , we have

$$\int_{x_0}^{x_1} \sum_{j=1}^n \left( F_{y_j} - \frac{d}{dx} F_{y_j'} \right) \delta y_j dx = 0, \quad (2)$$

Since

$$\delta v = \int_{x_0}^{x_1} \sum_{j=1}^n (F_{y_j} \delta y_j + F_{y_j'} \delta y_j') dx = \int_{x_0}^{x_1} \sum_{j=1}^n \left( F_{y_j} - \frac{d}{dx} F_{y_j'} \right) \delta y_j dx$$

Adding termwise all the equations (1) and equation (2) and introducing the notation

$$\bar{F} = F + \sum_{i=1}^m \lambda_i(x) \phi_i$$

we have

$$\int_{x_0}^{x_1} \sum_{j=1}^n \left( \bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} \right) \delta y_j dx = 0 \quad (3)$$

Since the variations  $\delta y_j, j = 1, 2, \dots, n$  are not arbitrary, we cannot yet use the fundamental lemma. Choose  $m$  factors  $\lambda_1(x), \lambda_2(x), \dots, \lambda_m(x)$  so that they satisfy the equations

$$\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0, \quad j = 1, 2, \dots, m$$

So for this we integrate each term of the second integral by parts and taking into considering that  $\delta y_j$  dash equal to  $\delta y_j$  whole dash and variation at the point  $x$  not and  $x_1$  is simply 0. So by doing this we have this condition  $x$  not to  $x_1$   $j$  equal to 1 to  $n$   $\lambda_i(x)$   $\frac{\partial \phi_i}{\partial y_j} \delta y_j$  and  $\delta y_j$  minus  $d$  by  $dx$  of  $\lambda_i(x) \frac{\partial \phi_i}{\partial y_j'}$  by  $\delta y_j$  dash into  $\delta y_j dx$  equal to 0.

Now we will proceed further so now let us consider the functional here from the basic necessary condition for an extremum  $\delta v$  has to be 0 which reduces to this condition  $x$  not to  $x_1$   $j$  equal to 1 to  $n$   $F$  of  $y_j$  minus  $d$  by  $dx$   $F$  of  $y_j$  dash  $\delta y_j dx$  is equal to 0. This we obtain from this that  $\delta y_j$  is equal to this  $x$  not to  $x_1$   $j$  equal to 1 to  $n$   $F$  of  $y_j$   $\delta y_j$  plus

$F$  of  $y_j$  dash  $\delta y_j$  dash  $d$  of  $x$ . So by transferring this derivative on this we are getting this equation number 2. So adding term vice all the equations 1 and equation 2.

So here we have this equation 1 which we obtain from the constraints and this which we obtain by necessary condition for extremum that is  $\delta v$  equal to 0 so here we add term by term and we get this notation  $\bar{F}$  equal to  $F$  plus summation  $i$  equal to 1 to  $m$   $\lambda_i(x) \phi_i$ . Then this equation 1 and 2 can be written in a concise form as 3. So here 3 is what  $x$  not to  $x_1$   $j$  equal to 1 to  $n$   $\bar{F}$   $y_j$  minus  $d$  by  $dx$  of  $\bar{F}$   $y_j$  dash  $\delta y_j$   $dx$  equal to 0, where  $\bar{F}$  is defined as  $F$  plus summation  $i$  equal to 1  $\lambda_i(x) \phi_i$ . Now again this variation  $\delta y_j$ ,  $j$  is from 1 to  $n$  are not arbitrary, we cannot use the fundamental lemma. So here as we done in a previous case we choose  $m$  factor  $\lambda_1$  to  $\lambda_m$  so that they satisfy the equation  $\bar{F}$   $y_j$  minus  $d$  by  $dx$  of  $\bar{F}$   $y_j$  dash equal to 0 for each  $j$  equal to 1 to  $m$ .

So this we did in previous case also the only difference between this case and the previous case is that in previous case this is resulting into system of a linear equation.

(Refer Slide Time: 7:38)

Adding termwise all the equations (1) and equation (2) and introducing the notation

$$\bar{F} = F + \sum_{i=1}^m \lambda_i(x) \phi_i$$

we have

$$\int_{x_0}^{x_1} \sum_{j=1}^n \left( \bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} \right) \delta y_j dx = 0 \quad (3)$$

Since the variations  $\delta y_j$ ,  $j = 1, 2, \dots, n$  are not arbitrary, we cannot yet use the fundamental lemma. Choose  $m$  factors  $\lambda_1(x), \lambda_2(x), \dots, \lambda_m(x)$  so that they satisfy the equations

$$\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0, \quad j = 1, 2, \dots, m$$

∞

7

After writing in expanded form, these equations form a system of linear differential equations in

$$\lambda_i(x) \text{ and } \frac{d\lambda_i}{dx}, \quad i = 1, 2, \dots, m$$

which has the solution  $\lambda_1(x), \lambda_2(x), \dots, \lambda_m(x)$ , which depends on  $m$  arbitrary constants. With this choice of  $\lambda_1(x), \lambda_2(x), \dots, \lambda_m(x)$ , (3) is reduced in the form

$$\int_{x_0}^{x_1} \sum_{j=m+1}^n \left( \bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} \right) \delta y_j dx = 0$$

where the variations  $\delta y_j, j = m + 1, \dots, n$  are now arbitrary, and hence, assuming all variations  $\delta y_j = 0$ , except some one  $\delta y_i$ , and applying the fundamental lemma, we obtain

But in this particular case this will reduce to system of an linear differential equation in  $\lambda_i x$  and  $d \lambda_i$  by  $d$  of  $x$ . So this is the only difference between the previous case and this case and since it is a linear differential equation and the involved functions  $F$  are  $\phi$  all are continuous. So we have existence guaranteed so and we can say that which has the solution  $\lambda_1$  to  $\lambda_m$  which depend on  $m$  arbitrary constants. Now with this choice of  $\lambda_1$  to  $\lambda_m$ .

Now this previous equation number 3 is reduced to from  $m + 1$  to  $n$  and we can say that it is  $x$  not to  $x_1$  summation  $m + 1$  to  $n$   $\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'}$  dash  $\delta y_j dx$  equal to 0. And here the variation  $\delta y_j, j$  from  $m + 1$  to  $n$  are now arbitrary and hence by assuming all variation except one as 0 we can apply the fundamental lemma.

(Refer Slide Time: 8:48)

$$\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0, \quad j = m + 1, m + 2, \dots, n$$

Thus, the functions  $y_1(x), \dots, y_n(x)$  that render the functional  $v$  a conditional extremum, and the factors  $\lambda_1(x), \lambda_2(x), \dots, \lambda_m(x)$  must satisfy the system of  $n + m$  equations

$$\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0, \quad j = 1, 2, \dots, n$$

and

$$\phi_i = 0, \quad i = 1, 2, \dots, m$$

i. e. they must satisfy the Euler equations of the auxiliary functional  $\bar{v}$ , which is regarded as a functional dependent on the  $n + m$  functions

$y_1, \dots, y_n, \lambda_1, \lambda_2, \dots, \lambda_m$ .

Adding termwise all the equations (1) and equation (2) and introducing the notation

$$\bar{F} = F + \sum_{i=1}^m \lambda_i(x) \phi_i$$

we have

$$\int_{x_0}^{x_1} \sum_{j=1}^n \left( \bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} \right) \delta y_j dx = 0 \quad (3)$$

Since the variations  $\delta y_j, j = 1, 2, \dots, n$  are not arbitrary, we cannot yet use the fundamental lemma. Choose  $m$  factors  $\lambda_1(x), \lambda_2(x), \dots, \lambda_m(x)$  so that they satisfy the equations

$$\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0, \quad j = 1, 2, \dots, m$$

And we can get the from the Euler equation that  $\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0$  for  $j = m+1$  to  $n$ . And so if we combine equation like this which we have obtained by choosing factors  $\lambda_1$  to  $\lambda_m$  with this condition here  $\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0$  which we obtain by applying the fundamental lemma. So now this will reduce to this this will extend to this  $\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0$  for  $j = 1$  to  $n$  along with the condition  $\phi_i = 0$  for  $i = 1$  to  $m$ . Now these are  $n+m$  equation which is sufficient to provide as the solution  $y_1$  to  $y_n$  and  $\lambda_1$  to  $\lambda_m$ .

So it means that the function  $y_1$  to  $y_n$   $x$  that render the functional  $v$  a conditional extremum and the factor  $\lambda_1$  to  $\lambda_m$   $x$  must satisfy the system of  $n+m$  equation which is given by this and this.

It means that they must satisfy the Eulers Equation of the auxiliary functional  $\bar{v}$ , which is regarded as functional dependent on the  $n+m$  functions. So if we consider  $\bar{v}$  as a function of this  $y_1$  to  $y_n$  and  $\lambda_1$  to  $\lambda_m$  then these  $n+m$  equation can be obtained through the Eulers Equation applied on this  $\bar{v}$ . So let us go to new problem and if you look at these this analysis is similar to the analysis which we have discussed in previous case the only change from previous study and this study is only these points let me remind you.

(Refer Slide Time: 10:52)

Let  $y_1, y_2, \dots, y_n$  be an arbitrary permissible system of functions that satisfies the constraint equations  $\phi_i = 0$  ( $i = 1, 2, \dots, m$ ). Vary the constraint equations

$$\sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j} \delta y_j + \sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j'} \delta y_j' = 0, \quad i = 1, 2, \dots, m$$

Multiply term by term each of the equations obtained by the (as yet) undetermined factor  $\lambda_i(x)$  and integrate from  $x_0$  to  $x_1$ ; this yields

$$\int_{x_0}^{x_1} \lambda_i(x) \sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j} \delta y_j dx + \int_{x_0}^{x_1} \lambda_i(x) \sum_{j=1}^n \frac{\partial \phi_i}{\partial y_j'} \delta y_j' dx = 0$$

Adding termwise all the equations (1) and equation (2) and introducing the notation

$$\bar{F} = F + \sum_{i=1}^m \lambda_i(x) \phi_i$$

we have

$$\int_{x_0}^{x_1} \sum_{j=1}^n \left( \bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} \right) \delta y_j dx = 0 \quad (3)$$

Since the variations  $\delta y_j$ ,  $j = 1, 2, \dots, n$  are not arbitrary, we cannot yet use the fundamental lemma. Choose  $m$  factors  $\lambda_1(x), \lambda_2(x), \dots, \lambda_m(x)$  so that they satisfy the equations

$$\bar{F}_{y_j} - \frac{d}{dx} \bar{F}_{y_j'} = 0, \quad j = 1, 2, \dots, m$$

One addition is here, right another addition is here in the in terms of equation so here we are getting a differential equation rather than simple finite a linear system of linear equation and rest are almost same.

(Refer Slide Time: 11:12)

**Isoperimetric Problem**

To obtain the necessary condition in an isoperimetric problem involving finding an extremum of a functional  $v = \int_{x_0}^{x_1} F dx$ , given the constraints  $\int_{x_0}^{x_1} F_i dx = l_i$ ,  $i = 1, 2, \dots, m$ , it is necessary to form the auxiliary functional

$$v^{**} = \int_{x_0}^{x_1} \left( F + \sum_{i=1}^m \lambda_i F_i \right) dx$$

where  $\lambda_i$  are constants and write the Euler equations for it. The arbitrary constants  $C_1, C_2, \dots, C_{2n}$  in the general solution of a system of Euler's equations and the constants  $\lambda_1, \lambda_2, \dots, \lambda_m$  are determined from the boundary conditions

$$y_j(x_0) = y_{j0}, \quad y_j(x_1) = y_{j1}, \quad j = 1, 2, \dots, n$$

10

So now let us move to new problem that is isoperimetric problem and this we have already studied.

(Refer Slide Time: 11:24)

$$z_i = \int_{x_0}^x G_i(x, x_1, \dots, x_n) dx, \quad z_i(x_0) = 0, \quad z_i(x_1) = l_i$$

$$\Rightarrow z_i'(x) = G_i(x, x_1, \dots, x_n) \Rightarrow \frac{z_i' - G_i(x, x_1, \dots, x_n)}{\phi_i} = 0$$

$$\psi[x_1, \dots, x_n] = \int_{x_0}^{x_1} F(x, y_1, \dots, y_n, x_1', \dots, x_n') dx.$$

$$\psi \phi_i(x, x_1, \dots, x_n) = 0$$

$$\psi \phi_i(x, x_1, \dots, x_n, x_1', \dots, x_n') = 0 \quad i = 1, \dots, m, m < n.$$

$$\int_{x_0}^{x_1} G_i(x, x_1, \dots, x_n) dx = l_i \quad i = 1, \dots, m, m < n.$$

The only difference between these previously discussed problem here that in first we have considered that finite equation conditions are given in terms of finite equation and now we have already discussed the case when constraints are nothing but system of system of differential equation. Now in case of isoperimetric problem your conditions are given in terms of integral equation. So here we have  $x$  not to  $x_1$  we have  $G_i$  say  $x, y_1$  to  $y_n$  and of  $x$  equal to 0 for each  $i$  equal to 1 to  $m$ ,  $m$  is less than  $n$ . So this also can be reduced to previous case by just assuming not 0 some values say  $l_i$ .

So this can be reduced to this so problem of extremum of this along with this condition are known as isoperimetric problem which we have already discussed but here we can observe that this problem can be reduced to the problem which we have just discussed by assuming a new variable that is  $z_i$  as  $x$  not to  $x$ , say  $G_i(x, y_1$  to say  $y_n$  and of  $x$ . So by here we can say that  $z_i$  is simply 0 and  $z_i$  your  $x_1$  is  $x_1$  is given as  $l$  of  $i$ .

So what is the advantage of considering this  $z_i$ ? That if we differentiate with respect to  $x$  here then we have  $z_i$  dash  $x$  is equal to  $G$  of  $i$   $x$ ,  $y_1$  to  $y_n$ . This I can write it as  $z_i$  dash minus  $j$  of  $i$   $x$ ,  $y_1$  to say  $y_n$  is equal to 0. So if we denote this as say  $\phi_i$  then this isoperimetric problem is reduced to the problem of finding the extremum of this functional along with this condition extremum, okay. So this we can solve. So taking this as  $\phi_i$  we can apply our discussion which we have just done just over and we can find out say the solution of the isoperimetric problem.

(Refer Slide Time: 14:02)

**Isoperimetric Problem**

To obtain the necessary condition in an isoperimetric problem involving finding an extremum of a functional  $v = \int_{x_0}^{x_1} F dx$ , given the constraints  $\int_{x_0}^{x_1} F_i dx = l_i$ ,  $i = 1, 2, \dots, m$ , it is necessary to form the auxiliary functional

$$v^{**} = \int_{x_0}^{x_1} \left( F + \sum_{i=1}^m \lambda_i F_i \right) dx$$

where  $\lambda_i$  are constants and write the Euler equations for it. The arbitrary constants  $C_1, C_2, \dots, C_{2n}$  in the general solution of a system of Euler's equations and the constants  $\lambda_1, \lambda_2, \dots, \lambda_m$  are determined from the boundary conditions

$$y_j(x_0) = y_{j0}, \quad y_j(x_1) = y_{j1}, \quad j = 1, 2, \dots, n$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 10

and from the isoperimetric conditions

$$\int_{x_0}^{x_1} F_i dx = l_i, \quad i = 1, 2, \dots, m.$$

The system of Euler's equations for the functional  $v^{**}$  does not vary if  $v^{**}$  is multiplied by some constant factor  $\mu_0$  and, hence, is given in the form

$$\mu_0 v^{**} = \int_{x_0}^{x_1} \sum_{i=0}^m \mu_i F_i dx$$

where  $F_0 = F$  and  $\mu_j = \lambda_j \mu_0, j = 1, 2, \dots, m.$

So we can see that to obtain the necessary condition in an isoperimetric problem involving finding an extremum of a functional  $v$  which is given as  $\int_{x_0}^{x_1} F dx$ , given the constraints  $\int_{x_0}^{x_1} F_i dx = l_i, i = 1, 2, \dots, m$ , it is necessary to form the auxiliary functional  $v^{**}$  that is  $\int_{x_0}^{x_1} F + \sum_{i=1}^m \lambda_i F_i dx$ . Where  $\lambda_i$  are constants and we can write the Euler Equation for this functional  $v^{**}$  this we can obtain from the previous discussion.

The arbitrary constants  $C_1$  to  $C_{2n}$  in the general solution of system of Euler's Equation and the constants  $\lambda_1$  to  $\lambda_m$  we can obtain these by boundary condition and boundary condition defined at both the end. And from the isoperimetric condition that is  $\int_{x_0}^{x_1} F_i dx = l_i, i = 1, 2, \dots, m$ . And the system of Euler's Equation for the functional  $v^{**}$  does not vary if  $v^{**}$  is multiplied by some constant factor.

So it means that if we already find out say extremal functional for  $v^{**}$  with the  $v^{**}$  then extremal curve will not change if we multiply by some nonzero constant that is  $\mu_0$  and we can say that  $\mu_0 v^{**} = \int_{x_0}^{x_1} \sum_{i=0}^m \mu_i F_i dx$ . So what we try to do here let us consider here.

(Refer Slide Time: 15:55)

$$z_i = \int_{x_0}^x G_i(x, x_1, \dots, x_n) dx, \quad z_i(x_0) = 0, \quad z_i(x_1) = \lambda_i$$

$$\Rightarrow z_i'(x) = G_i(x, x_1, \dots, x_n) \Rightarrow \frac{z_i' - G_i(x, x_1, \dots, x_n)}{\phi_i} = 0$$

$$\checkmark U[x_1, \dots, x_n] = \int_{x_0}^{x_1} F(x, y_1, \dots, y_n, x_1', \dots, x_n') dx.$$

$$\mu_0 U^{**} = \int_{x_0}^{x_1} \left( F + \sum_{i=1}^m \lambda_i G_i \right) dx = \int_{x_0}^{x_1} \left( \sum_{i=0}^m \mu_i F_i \right) dx$$

$$\checkmark \int_{x_0}^{x_1} G_i(x, x_1, \dots, x_n) dx = \lambda_i \quad i=1, \dots, m, \quad m < n.$$

$F_0 = F$   
 $F_i = G_i$   
 $\mu_i = \lambda_i \mu_0$

So what we are doing here we are having a problem this we are considering this problem along with this condition. So for this we consider  $v$  double star as  $x$  not to  $x_1$  we call this as  $F$  plus here we have  $\lambda_i$  summation  $\lambda_i$  you can write it  $G_i$ ,  $i$  is from 1 to  $m$   $d$  of  $x$ . So here we consider this as  $F$  bar and we simply find out the Eulers Equation for this. Now if we multiply both side by any constraint say  $\mu_0$  not then also there is no change in solution of Eulers Equation.

So what we can do here? We rewrite this as integral  $x$  not to  $x_1$  and we can write this as  $i$  equal to 0 to  $m$  rather than from starting from 1 to  $m$  and we can write this as say  $\mu_i$  and we can write it your  $F_i$  and  $d$  of  $x$ . So here your  $F_0$  is your  $F$  and your  $F_i$  is your  $G_i$  and your  $\mu_i$  is equal to  $\lambda_i \mu_0$ . So here we can simply write that  $\mu_0$  not  $\mu_0$  not  $v$  double star is given as  $x$  not to  $x_1$  summation  $i$  equal to 0 to  $m$   $\mu_i F_i d$  of  $x$  the purpose behind behind doing this that now this is symmetric in all  $F_i$  and we can say that and we can say that.

(Refer Slide Time: 17:40)

and from the isoperimetric conditions

$$\int_{x_0}^{x_1} F_i dx = l_i, \quad i = 1, 2, \dots, m.$$

The system of Euler's equations for the functional  $v^{**}$  does not vary if  $v^{**}$  is multiplied by some constant factor  $\mu_0$  and, hence, is given in the form

$$\mu_0 v^{**} = \int_{x_0}^{x_1} \sum_{i=0}^m \mu_i F_i dx$$

where  $F_0 = F$  and  $\mu_j = \lambda_j \mu_0, j = 1, 2, \dots, m.$

11

So here F not is F and Mu j is lambda j Mu not for j equal to 1 to m.

(Refer Slide Time: 17:45)

Now all the functions  $F_i$  enter symmetrically, and therefore the extremals in the original variational problem and in the problem involving finding an extremum of the functional  $\int_{x_0}^{x_1} F_s dx$  given the isoperimetric conditions

$$\int_{x_0}^{x_1} F_i dx = l_i, \quad i = 0, 1, 2, \dots, s-1, s+1, \dots, m$$

coincide with any choice of  $s, s = 0, 1, \dots, n.$  This property is called the reciprocity principle.

12

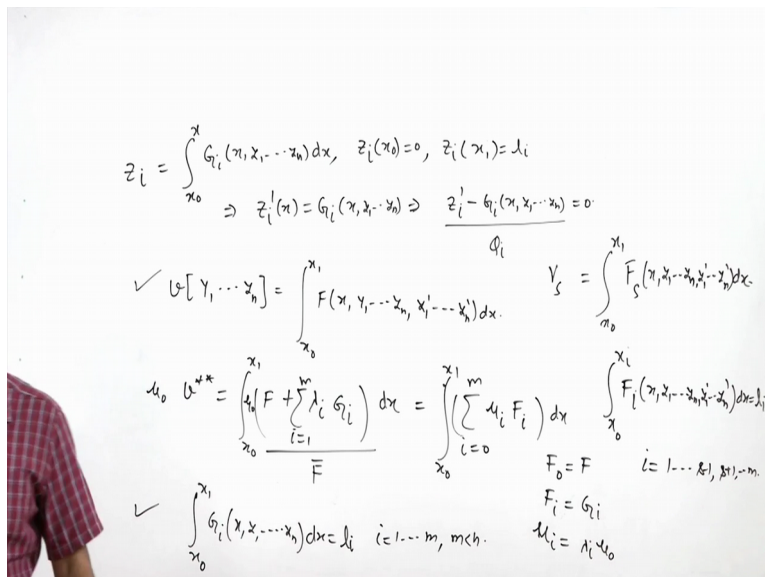

The purpose is that now all the functions  $F_i$  enter in a symmetric manner and therefore the extremal in the original variational problem and in the problem involving finding an extremum of the functional  $\int_{x_0}^{x_1} F_s dx$  given the isoperimetric condition  $\int_{x_0}^{x_1} F_i dx = l_i$ , where  $i$  is from 0 to  $s-1$ , comma  $s+1$  to  $m$  coincide.

(Refer Slide Time: 18:14)

It means that coming back to this the purpose behind doing this is that if you look at we want to extremize this functional along with this condition and for that we have seen that the extremal functional basically satisfy the Eulers Equation corresponding to this variational problem this functional.

(Refer Slide Time: 18:34)

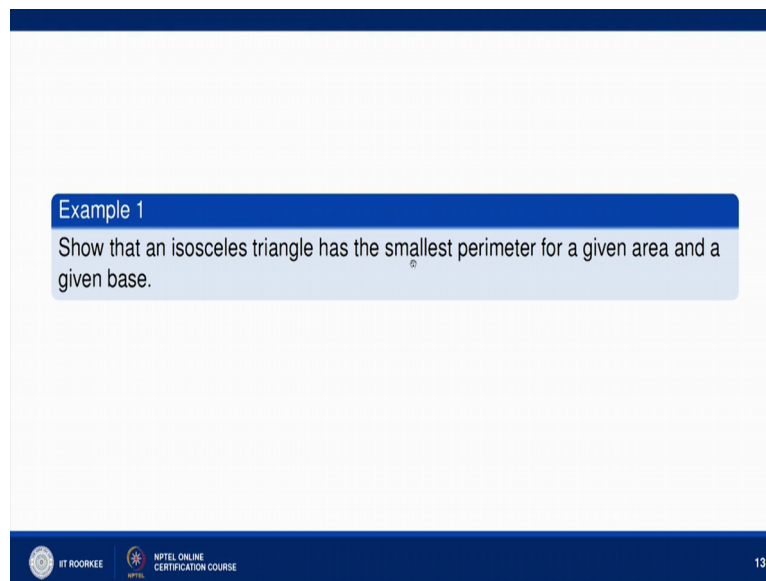

So here we can say that that code of these m plus 1 functionals we can say that let us extremize say let us say extremize x not to x 1 we can take out of these F i from 0 to m here, you can take any say function let us say that you take F of s x, y 1 to say y n and y 1 dash to y n dash d of x we want to say let us extremize this let us call this as V of s here keeping others as condition. So we can say that now conditions are reduced as (x not to x 1) x not to x n F of

$y_1$  to say  $y_n$  and  $y_1$  dash to  $y_n$  dash d of  $x$  equal to  $l_i$ , where here  $i$  is running from 1 to  $s$  minus 1 leaving this  $s$  out,  $s$  plus 1 to say  $m$ .

So it means that here you can take you can take you can extremize any of the integral keeping all other integral as constant then also your extremal functional will not change and it will in all these cases your you have to form this kind of function and your extremal functional functions will has to satisfy the Eulers Equation corresponding to this functional  $\mu$  not  $v$  double star. So this property is known as reciprocity principle.

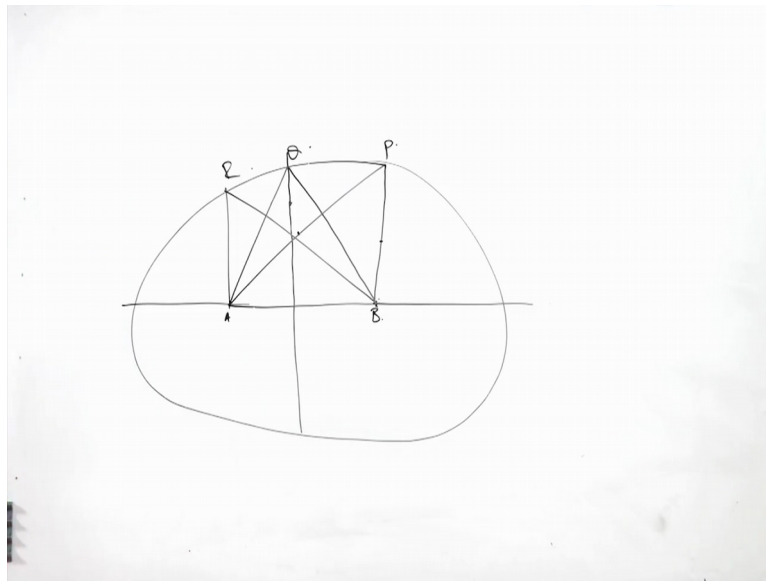

(Refer Slide Time: 20:20)

The slide features a dark blue header and footer. The main content area is white with a light blue gradient. A dark blue box contains the text 'Example 1' in white. Below it, a light blue box contains the text 'Show that an isosceles triangle has the smallest perimeter for a given area and a given base.' The footer contains the logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, along with the page number 13.

So here we discuss the first example which says that show that an isosceles triangle has the smallest parameter for a given area and a given base. So here we try to use the reciprocity principle to solve this particular problem. So we try to solve this problem by saying that a triangle isosceles triangle having the given perimeter and a given base has say maximum area.

(Refer Slide Time: 20:52)

So if you look at here let us take the base, base is already given let us say that this base is given as A and B and perimeter is fixed here. So let us say that perimeter is some kind of  $l$  and we want to find out say triangle having the maximum area and we try to show that that triangle is an isosceles triangle. So what we try to do here? Let us consider an ellipse whose focus are situated here and keeping this A, B as major axis and let us consider this as y axis here and let us consider this as the perimeter, this plus this is the perimeter here and vary this and we can have a an ellipse kind of figure here.

So here you can say that by the property of an ellipse if we take any triangle keeping the base point as A, B then the area for perimeter is going same. So we can consider this as P, we can say that Q and we can consider this R. So we can say that the perimeter of PAB, QAB and RAB will be the same that is that can be shown in a with the property of an ellipse. But the area of this AQB is going to be the highest the reason being that this is the having the highest say height. So this AQB will the highest AQB will be the will be a triangle having the maximum area because of it is having the highest height.

So we can say that this AQB is the triangle having the same perimeter but having the maximum area. So this can be considered with the help of reciprocity principle that given a given that isosceles triangle has the smallest perimeter for a given area and a given base. So with the help of reciprocity principle we can say that isosceles triangle has the smallest perimeter for a given area and a given base.

(Refer Slide Time: 23:42)

**Example 2**

Find the shape of an absolutely flexible, inextensible homogeneous and heavy rope of given length  $l$  suspended at the points  $A$  and  $B$ . The rope in equilibrium takes a shape such that its center of gravity occupies the lowest position. Thus we have to find the minimum of the  $y$ -coordinate of the center of gravity of the string given by

$$I[y(x)] = \frac{\int_{x_1}^{x_2} y \sqrt{1 + y'^2} dx}{\int_{x_1}^{x_2} \sqrt{1 + y'^2} dx} \quad (4)$$

subject to the constraint

$$\int_{x_1}^{x_2} \sqrt{1 + y'^2} dx = l \quad (5)$$

BIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

This implies that we have to minimize the numerator of the right hand side of (4) subject to (5). Therefore, we form the functional

$$I^* = \int_{x_1}^{x_2} (y + \lambda) \sqrt{1 + y'^2} dx,$$

where  $\lambda$  is a constant. The first integral of the Euler equation for this functional is  $y + \lambda = C_1 \sqrt{1 + y'^2}$ , where  $C_1$  is a constant. Introducing

$$y' = \sinh t$$

we get

$$y + \lambda = C_1 \cosh t$$

BIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

Now moving on to second example here we want to find out the shape of an absolute absolutely flexible, inextensible homogeneous and heavy rope of a given length  $l$  suspended at the points  $A$  and  $B$ . And the rope in equilibrium takes a shape such that its center of gravity occupies the lowest position. So we try to find out the shape of such a rope. So here we use a condition that in equilibrium position the shape it will any rope will take a shape such that its center of gravity occupies the lowest position.

So we need to find out the minimum of the  $y$  coordinate of the center of gravity of the string given by this. So  $I$  of  $y$  of  $x$  is given by  $(x_1 \text{ to } x_2) \int_{x_1}^{x_2} y \sqrt{1 + y'^2} dx$  divided by  $(x_1 \text{ to } x_2) \int_{x_1}^{x_2} \sqrt{1 + y'^2} dx$  keeping the constraint  $(x_1 \text{ to } x_2) \int_{x_1}^{x_2} \sqrt{1 + y'^2} dx = l$ . So this constraint tells

you that the length is constant and it is given as  $l$ . So we want to find extremize the functional this keeping this constraint in mind.

So here we want to this implies that we have to minimize the numerator of the right hand side of 4 subject to 5. So we want to minimize the this numerator keeping this thing as constant that is  $l$ . So here we form the functional  $I$  star that is  $x$  1 to  $x$  2  $y$  plus lambda under root 1 plus  $y$  dash square d of  $x$  and here lambda is a constant.

(Refer Slide Time: 25:21)

The image shows a handwritten derivation on a whiteboard. The steps are as follows:

$$F = (y + \lambda) \sqrt{1 + y'^2} \quad \Rightarrow \quad x + \lambda = C_1 \sqrt{1 + y'^2}$$

$$F - y' F_{y'} = C_1$$

$$(x + \lambda) \sqrt{1 + y'^2} - y' \frac{(y + \lambda) y'}{\sqrt{1 + y'^2}} = C_1$$

$$\frac{(x + \lambda)(1 + y'^2) - y'^2 (y + \lambda)}{\sqrt{1 + y'^2}} = C_1 \sqrt{1 + y'^2}$$

$$\Rightarrow (x + \lambda) [1] = C_1 \sqrt{1 + y'^2}$$

So if you look at if you form the Euler Equation for this then  $F$  is given as  $y$  plus lambda under root 1 plus  $y$  dash square  $y$  dash square. Now here  $F$  is independent of independent variable  $x$ . So here your Eulers Equation reduce to  $F$  minus  $y$  dash  $F$  of  $y$  dash equal to constant, constant let us say  $C_1$ . The  $F$  is  $y$  plus lambda under root 1 plus  $y$  dash square minus  $y$  dash. Now  $F$  of  $y$  dash will be what  $y$  plus lambda and here we will get 2 into 1 plus  $y$  dash square 2 of  $y$  dash is equal to  $C_1$ , so 2, 2 will be cancelled out.

And here we can say that  $y$  plus lambda then multiply here so we have 1 plus  $y$  dash square minus  $y$  dash  $y$  dash square  $y$  plus lambda equal to  $C_1$  under root 1 plus  $y$  dash square. So here we can take this  $y$  plus lambda out, so  $y$  plus lambda out and inside you can say that it is 1 equal to  $C_1$  under root 1 plus  $y$  1 dash square  $y$  dash square. So here we can say that  $y$  plus lambda is equal to  $C_1$  under root 1 plus  $y$  1  $y$  dash square. So it is  $y$  dash square. So we want to simplify this for simplifying this we can introduce a new parameter  $t$  so by saying that  $y$  dash equal to  $\sin$  hyperbolic  $t$  then  $y$  plus lambda can be written as  $C_1$  under root 1 plus  $\sin$  hyperbolic square  $t$  can be written as  $y$  plus lambda equal to  $C_1 \cos$  hyperbolic  $t$ .

(Refer Slide Time: 27:04)

Giving

$$dx = \frac{dy}{y'} = C_1 dt.$$

Thus

$$x = C_1 t + C_2.$$

So

$$y + \lambda = C_1 \cosh[(x - C_2)/C_1]$$

is the desired curve which is a Catenary. The three constants  $\lambda$ ,  $C_1$  and  $C_2$  are determined from (5) and the boundary conditions that the rope passes through  $A$  and  $B$ .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 16

### Example 2

Find the shape of an absolutely flexible, inextensible homogeneous and heavy rope of given length  $l$  suspended at the points  $A$  and  $B$ . The rope in equilibrium takes a shape such that its center of gravity occupies the lowest position. Thus we have to find the minimum of the  $y$ -coordinate of the center of gravity of the string given by

$$I[y(x)] = \frac{\int_{x_1}^{x_2} y \sqrt{1 + y'^2} dx}{\int_{x_1}^{x_2} \sqrt{1 + y'^2} dx} \quad (4)$$

subject to the constraint

$$\int_{x_1}^{x_2} \sqrt{1 + y'^2} dx = l \quad (5)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

So now we can find out say parameter representation of  $x$  that is  $dx$  equal to  $dy$  upon  $y'$  that is  $C_1 dt$  and we can say that  $x$  is equal to  $C_1 t + C_2$ , so taking  $t$  from this equation we can say that  $t$  can be written as  $(x - C_2)/C_1$ . So  $y + \lambda$  can be written as  $C_1 \cosh[(x - C_2)/C_1]$ . So the shape of the hanging rope can be will be satisfying this equation which is the curve which is known as catenary equation. And the constant  $\lambda$ ,  $C_1$  and  $C_2$  can be obtained from the condition this and the boundary condition satisfy by the problem, okay.

(Refer Slide Time: 27:54)

**Theory of Optimal Control**

Find the control function  $u(t) = (u_1, u_2, \dots, u_m)^T$ , which extremizes the functional, called the performance index

$$I = \int_0^{T_0} f_0(x, u, t) dt \quad (6)$$

where  $x(t) = (x_1, x_2, \dots, x_n)^T$  is called the state vector,  $t$  is the time parameter,  $T_0$  is the terminal time and  $f_0$  is a given function of  $x, u$ , and  $t$ . The relations between  $x(t)$  and  $u(t)$  are given by

$$\frac{dx_i}{dt} = f_i(x_1, x_2, \dots, x_n; u_1, u_2, \dots, u_m), \quad i = 1, 2, \dots, n. \quad (7)$$

BIT ROORKEE  
NPTL  
NPTL ONLINE CERTIFICATION COURSE  
17

So now let us also discuss a new problem which is known as finding the control which optimize a certain functional. So here the problem is as follows. Find the control function  $u$   $t$  which is  $u_1$  to  $u_m$  transpose which extremizes the functional which is known as performance index  $I$  which is defined as  $\int_0^{t_{not}} f(x, u, t) dt$ . Here  $x$  is a state vector given as  $x_1$  to  $x_n$  transpose and  $t$  is the time parameter and  $t_{not}$  is the terminal time and  $f$  is a given function of  $x, u$  and  $t$ .

And the relation between the control vector and the state vector is given by this equation which is given as differential equation and it is defined as  $\frac{dx_i}{dt} = f_i(x_1, x_2, \dots, x_n, u_1, \dots, u_m)$ . So your control variable and state variables are given by this and we want to find out the control which extremizes the functional. So this is a very common problem in theory of optimal control and we want to extremize the the corresponding functional this.

(Refer Slide Time: 29:12)

As in an isoperimetric problem, we introduce Lagrange multipliers  $\lambda_i(t)$  and form augmented functional  $I^*$  from (6) and (7) as follows:

$$I^* = \int_0^{T_0} \left[ f_0 + \sum_{i=1}^n \lambda_i (f_i - \dot{x}_i) \right] dt, \quad (8)$$

where the dot over the vector  $x$  denotes the derivative with respect to time. Introducing the Hamiltonian functional  $H$  as

$$H = f_0 + \sum_{i=1}^n \lambda_i f_i \quad (9)$$

we find from (8),

$$I^* = \int_0^{T_0} (H - \sum_{i=1}^n \lambda_i \dot{x}_i) dt. \quad (10)$$

18

## Theory of Optimal Control

Find the control function  $u(t) = (u_1, u_2, \dots, u_m)^T$ , which extremizes the functional, called the performance index

$$I = \int_0^{T_0} f_0(x, u, t) dt \quad (6)$$

where  $x(t) = (x_1, x_2, \dots, x_n)^T$  is called the state vector,  $t$  is the time parameter,  $T_0$  is the terminal time and  $f_0$  is a given function of  $x, u,$  and  $t$ . The relations between  $x(t)$  and  $u(t)$  are given by

$$\frac{dx_i}{dt} = f_i(x_1, x_2, \dots, x_n; u_1, u_2, \dots, u_m), \quad i = 1, 2, \dots, n. \quad (7)$$

17

So as in a isoperimetric problem we introduce a Lagrange multiplier  $\lambda_i(t)$  and form augmented functional  $I^*$  that is given as  $\int_0^{T_0} [f_0 + \sum_{i=1}^n \lambda_i (f_i - \dot{x}_i)] dt$ . So previous equation number 7 can be written as  $f_i - \dot{x}_i = 0$ , so this can be considered as constraint given in terms of differential equation.

So here we form the functional  $I^*$  which is given by this. Now here  $\dot{x}_i$  denote the derivative with respect to time  $t$ . Now here we denote this portion  $f_0 + \sum_{i=1}^n \lambda_i f_i$  as  $H$  which is known as Hamiltonian functional  $H$ . Now in term of Hamiltonian functional  $H$  we can rewrite this  $I^*$  as  $\int_0^{T_0} (H - \sum_{i=1}^n \lambda_i \dot{x}_i) dt$ .

(Refer Slide Time: 30:10)

The Euler equations are

$$\frac{\partial H}{\partial x_i} = -\lambda'_i, \quad i = 1, 2, \dots, n, \quad (11)$$

$$\frac{\partial H}{\partial u_j} = 0, \quad j = 1, 2, \dots, m. \quad (12)$$

The optimal solutions for  $x$ ,  $u$  and  $\lambda$  are obtained by solving (7), (11) and (12). In fact, these are  $2n + m$  equations for  $x'_i$ 's,  $u'_j$ 's and  $\lambda'_i$ 's. If the initial conditions  $x_i(0) = 0$ , ( $i = 1, 2, \dots, n$ ) and the terminal conditions  $x_j(T_0)$ , ( $j = 1, 2, \dots, l$ ),  $l < n$  are known, then the terminal values  $x_j(T_0)$  for  $j = l + 1, l + 2, \dots, n$  are free. In this case we use the free end conditions

$$\lambda_j(T) = 0, \quad j = l + 1, l + 2, \dots, n. \quad (13)$$

The equations (13) are known as the transversality conditions.

As in an isoperimetric problem, we introduce Lagrange multipliers  $\lambda_i(t)$  and from augmented functional  $I^*$  from (6) and (7) as follows:

$$I^* = \int_0^{T_0} \left[ f_0 + \sum_{i=1}^n \lambda_i (f_i - \dot{x}_i) \right] dt, \quad (8)$$

where the dot over the vector  $x$  denotes the derivative with respect to time. Introducing the Hamiltonian functional  $H$  as

$$H = f_0 + \sum_{i=1}^n \lambda_i f_i \quad (9)$$

we find from (8),

$$I^* = \int_0^{T_0} \left( H - \sum_{i=1}^n \lambda_i \dot{x}_i \right) dt. \quad (10)$$

## Theory of Optimal Control

Find the control function  $u(t) = (u_1, u_2, \dots, u_m)^T$ , which extremizes the functional, called the performance index

$$I = \int_0^{T_0} f_0(x, u, t) dt \quad (6)$$

where  $x(t) = (x_1, x_2, \dots, x_n)^T$  is called the state vector,  $t$  is the time parameter,  $T_0$  is the terminal time and  $f_0$  is a given function of  $x$ ,  $u$ , and  $t$ . The relations between  $x(t)$  and  $u(t)$  are given by

$$\frac{dx_i}{dt} = f_i(x_1, x_2, \dots, x_n; u_1, u_2, \dots, u_m), \quad i = 1, 2, \dots, n. \quad (7)$$

So as we pointed out we find out say Eulers Equation and Eulers Equation is nothing but deba H by deba x i equal to minus lambda i dash, for i equal to 1 to n and deba H by deba u j equal to 0 that is j equal to 1 to m. So what we did we find out say Eulers Equation for this and which result in this n plus m equations. So the optimal solution for x, comma u and lambda are obtained by solving the set of equation that is 7 and the set of equation which we have obtained through the Eulers Equation and so these are in fact these are 2n plus m equations for which x, u and lambda i can be obtained.

So if the initial condition x i is are given at and and 0 and the terminal condition x j given at t not are known and if the conditions are less in number we can always define lambda j at terminal say T as 0 and these kind of conditions are known as transversality conditions.

(Refer Slide Time: 31:24)

Consider for example the problem of finding the optimal control  $u$  which makes the functional

$$I = \int_0^l (x^2 + u^2) dt$$

stationary with  $x(0) = 1$  and  $\frac{dx}{dt} = u$ . Here the Hamiltonian function is

$$H = x^2 + u^2 + \lambda u.$$

Hence (11) and (12) give

$$2x = -\dot{\lambda}, \quad 2u + \lambda = 0$$

which along with  $\frac{dx}{dt} = u$  leads to

$$\ddot{x} - x = 0.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 20

The Euler equations are

$$\frac{\partial H}{\partial x_i} = -\dot{\lambda}_i, \quad i = 1, 2, \dots, n, \quad (11)$$

$$\frac{\partial H}{\partial u_j} = 0, \quad j = 1, 2, \dots, m. \quad (12)$$

The optimal solutions for  $x$ ,  $u$  and  $\lambda$  are obtained by solving (7), (11) and (12). In fact, these are  $2n + m$  equations for  $x_i$ 's,  $u_j$ 's and  $\lambda_j$ 's. If the initial conditions  $x_i(0) = 0$ , ( $i = 1, 2, \dots, n$ ) and the terminal conditions  $x_j(T_0)$ , ( $j = 1, 2, \dots, l$ ),  $l < n$  are known, then the terminal values  $x_j(T_0)$  for  $j = l + 1, l + 2, \dots, n$  are free. In this case we use the free end conditions

$$\lambda_j(T) = 0, \quad j = l + 1, l + 2, \dots, n. \quad (13)$$

The equations (13) are known as the transversality conditions.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 19

So let us consider one quick example on this, so here we consider the example of finding the optimal control  $u$  which makes the functional stationary with the condition that  $x$  of 0 is equal to 1 and  $dx$  by  $dt$  is equal to  $u$ . So control and state variable is related with this differential equation  $dx$  by  $dt$  equal to  $u$ . So here as pointed out we can form the Hamiltonian function as  $H$  equals to  $x$  square plus  $u$  square plus  $\lambda u$  and we can apply the Eulers Equation which is given in  $\frac{\partial H}{\partial x} = -\dot{\lambda}$  and  $\frac{\partial H}{\partial u} = 0$ .

So if we do this we have this equation  $2x$  equal to  $-\dot{\lambda}$  which we get from equation number 11 and  $\frac{\partial H}{\partial u} = 0$  we will get this  $2u$  plus  $\lambda$  equal to 0. So here  $u$  is given as  $dx$  by  $dt$ , so if you use this and you can take out  $\lambda$  here and put it here and we can say that equation that state vector satisfy is this second order differential equation.

(Refer Slide Time: 32:30)

Its solution satisfying  $x(0) = 1$  is

$$x(t) = C_1 \sinh t + \cosh t.$$

Since  $x$  is not specified at the terminal point  $T_0 = 1$ , we take  $\lambda = 0$  at  $t = 1$ . This at once gives  $u(1) = 0$  from  $2u + \lambda = 0$ . Since  $u = \dot{x}$ , we immediately get  $C_1 = -\frac{\sinh 1}{\cosh 1}$ . Thus the optimal control is

$$u(t) = -\frac{\sinh(1-t)}{\cosh 1}.$$

The corresponding state vector is given by

$$x(t) = \frac{\sinh(1-t)}{\cosh 1}.$$

21

Consider for example the problem of finding the optimal control  $u$  which makes the functional

$$I = \int_0^1 (x^2 + u^2) dt$$

stationary with  $x(0) = 1$  and  $\frac{dx}{dt} = u$ . Here the Hamiltonian function is

$$H = x^2 + u^2 + \lambda u.$$

Hence (11) and (12) give

$$2x = -\dot{\lambda}, \quad 2u + \lambda = 0$$

which along with  $\frac{dx}{dt} = u$  leads to

$$\ddot{x} - x = 0.$$

And whose solution is given  $x$  of  $C_1 \sin$  hyperbolic  $t$  plus  $C_2 \cos$  hyperbolic  $t$ . Now  $C_2$  we can obtain by the condition which is given at  $x$  of  $0$  is equal to  $1$ . So we can obtain  $C_2$  as  $1$  so your  $x$   $t$  is given as  $C_1 \sin$  hyperbolic  $t$  plus  $\cos$  hyperbolic  $t$ . Now we do not have any way to find out the  $C_1$  because  $x$  is not specified at the terminal point  $T$  not. So for that let us take  $\lambda$  equal to  $0$  at  $t$  equal to  $1$  so this at once gives  $u$  at  $1$  equal to  $0$ . Because we have this equation  $2u$  plus  $\lambda$  equal to  $0$ , so at  $t$  equal to  $1$  if  $\lambda$  at  $1$  is equal to  $0$  so  $u$  at  $1$  is equal to  $0$ . So  $u$  at  $1$  equal to  $0$  means  $\frac{dx}{dt}$  is equal to  $0$  at  $x$  equal to  $1$ .

So we can say that  $u$  equal to  $x$  dot and we immediately get  $C_1$  equal to  $-\frac{\sin \text{hyperbolic } 1}{\cos \text{hyperbolic } 1}$ . So using this value of  $C_1$  you can write down the value of  $x$   $t$  and hence we can find out the optimal control like this. So  $u$   $t$  is defined as  $-\frac{\sin \text{hyperbolic } 1 - t}{\cos \text{hyperbolic } 1}$  and the corresponding state vector is given by  $x$  of  $t$  equal to  $\frac{\sin \text{hyperbolic } 1 - t}{\cos \text{hyperbolic } 1}$ .

(Refer Slide Time: 33:58)

$$F = (\gamma + \lambda) \sqrt{1 + \gamma^2} \Rightarrow x + \lambda = c_1 \sqrt{1 + \gamma^2}$$

$$F - \gamma^1 F_{\gamma^1} = c_1$$

$$(x + \lambda) \sqrt{1 + \gamma^2} - \gamma^1 \frac{(\gamma + \lambda) \gamma^1}{\sqrt{1 + \gamma^2}} = c_1$$

$$(x + \lambda) (1 + \gamma^2) - \gamma^2 (\gamma + \lambda) = c_1 \sqrt{1 + \gamma^2}$$

$$\Rightarrow (x + \lambda) [1] = c_1 \sqrt{1 + \gamma^2}$$

$$\phi(x_1, \dots, x_n) = \int_{x_0}^{x_1} (\gamma x_1 - x_2, x_1' - x_2') dx$$

$$\phi_i(x_1, x_2, \dots, x_n) = 0, \quad i = 1 \dots m$$

$$\phi_c(x_1, x_2, \dots, x_n, x_1', x_2', \dots, x_n') = 0, \quad i = 1 \dots m$$

So here in today's lecture we have seen few things first thing we consider the variational problem with so variational problem is we have say  $y_1$  to say  $y_n$  which is given as say  $x$  not to  $x_1$  f of  $x$ , comma  $y_1$  to say  $y_n$  and  $y_1$  dash to say  $y_n$  dash d of  $x$  and we have considered the case when conditions are constant given in terms of finite equation that is  $x$ , comma  $y_1$  to  $y_n$  is equal to 0,  $i$  is from 1 to say  $m$  that we have discussed in previous lecture.

And in today's lecture we have discussed the constraint of the form given in terms of differential equation like this  $i$  equal to 1 to say  $m$  and also we have discussed the principle known as reciprocity principle and with the help of reciprocity principle we have discussed certain problem and then as an example of this case we have discussed a case of optimal control.

And here it is to be pointed out that this optimal control is not lying on the boundary of the set of admissible control, if it is then we have a separate theory not this theory will not work for the control which lie on the boundary of the set of admissible control. So here I stop and we will discuss in next lecture, so thank you very much for listening us meet in next lecture, thank you.
