Variational problems with moving boundaries-1

Hello friends welcome to my lecture on variational problems with moving boundaries.

(Refer Slide Time: 0:30)

Variational problem with a movable boundaries:

In extremizing the functional

$$I[y(x)] = \int_{x_1}^{x_2} F(x, y, y') dx. \quad \dots(1)$$

so far we took the boundary points (x_1, y_1) and (x_2, y_2) in the functional (1) as fixed. Now we consider the case when one or both the boundary points can move. Then the class of admissible curves will be extended because in addition to the comparison curves with fixed boundary points, we have to also consider curves with variable boundary points.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 2

So far we extremize the functional $I[y(x)] = \int_{x_1}^{x_2} F(x, y, y') dx$ where both the boundary points x_1, y_1 and x_2, y_2 were taken as fixed. Now we shall consider the case where one or both the boundary points x_1, y_1 can move. So the class of admissible curves will be extended because in addition to the comparison curves with fixed boundary points, we have also to consider curves with variable boundary points.

(Refer Slide Time: 1:00)

Consequently, if on a curve $y = y(x)$, an extremum is attained in a problem with moving boundary points, then certainly the extremum will also be attained on a restricted class of curves with fixed boundary points and hence the basic condition for attaining an extremum in a problem with fixed boundaries must be satisfied. Thus, the curves $y = y(x)$ on which extremum of the functional (1) is attained in a moving boundary problem must be solutions of the Euler equation

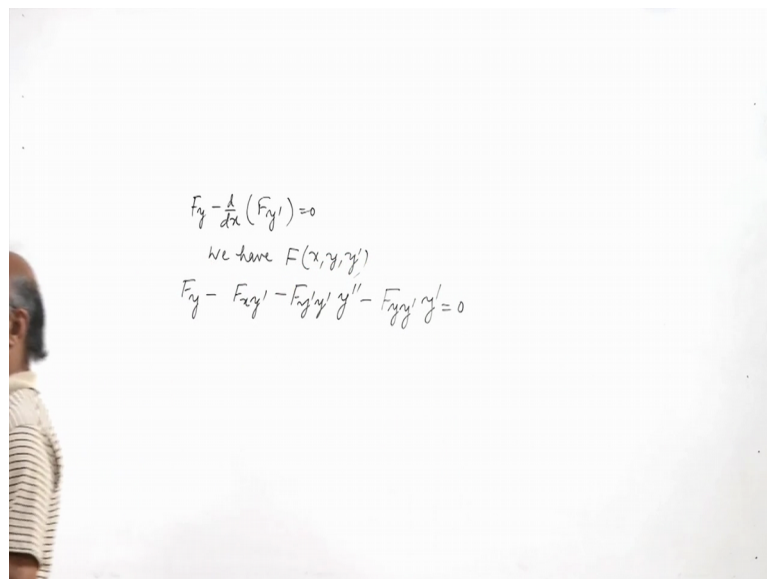

$$\frac{\partial F}{\partial y} - \frac{d}{dx} \left(\frac{\partial F}{\partial y'} \right) = 0, \quad \dots(1)$$

so that these curves must be extremals.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

Now consequently, if on a curve y equal to y x , an extremum is attained in a problem with moving boundary points, then certainly the extremum will also be attained on a restricted class of curves with fixed boundary points and hence the basic condition for attaining an extremum in a problem with fixed boundaries must be satisfied. And we know the condition for the extremum in the problem with fixed boundaries it is that the curves y equal to y x on which the extremal of the functional 1 is attained must be solutions of the equation F_y minus d over dx F_y dash equal to 0, so that these curves must be extremals.

(Refer Slide Time: 1:52)

On expanding this equation F_y minus d over dx F_y dash equal to 0, F_y dash is equal to 0. Now we know that we have F as a function of x, y, y dash. So when we differentiate F_y dash

what we will have with respect to x we shall have derivative of F derivative of F x y dash then we have derivative of F y dash y dash and we also have we will differentiate this with respect to x then we differentiate this with respect to y and we differentiate it with respect y dash and y dash we differentiate with respect to x, so we get y double dash, we differentiate this with respect to x we get F x y dash, we differentiate this with respect to y dash and then y dash is differentiated with respect to x so that we get this. And then we differentiate it with respect to y and then y is differentiated with respect to x.

(Refer Slide Time: 3:21)

On expanding (2), we find that

$$F_y - F_{xy'} - F_{yy'}y' - F_{yy''}y'' = 0,$$

which is, in general, a second order differential equation in $y(x)$ so its general solution contains two arbitrary constants which are determined from the two boundary conditions $y(x_1) = y_1$ and $y(x_2) = y_2$ in the problem with fixed boundary points. But in a moving boundary value problem one or both of these conditions are missing and therefore the missing condition (or conditions) for a determination of the arbitrary constants of the general solution of the Euler's equation have to be obtained from the basic necessary condition for an extremum which is the vanishing of the variation δI .

NPTEL ONLINE CERTIFICATION COURSE

4

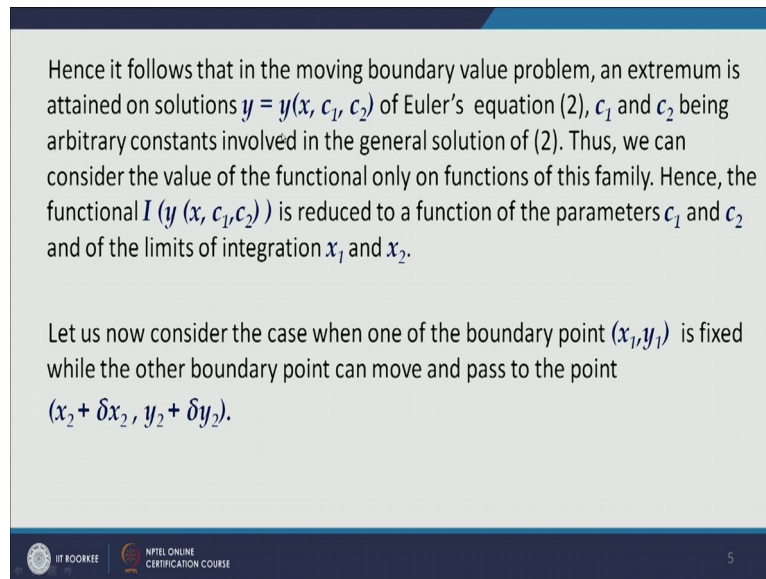

So we get F y minus F x y dash we get F y minus F x y dash minus F y y dash into y dash minus F y y dash F y dash y dash into y double dash equal to 0. Now this is a second order differential equation in y x so its solution will involve two arbitrary constants and these two arbitrary constants can be determined from the two boundary conditions y x 1 equal to y 1 and y x 2 equal to y 2 in the problem with fixed boundary points.

Now in the case of a moving boundary problem one or both of these conditions are missing and therefore the missing condition are conditions if one boundary point is fixed there will be one mixing condition, if both the boundary points are moving then then we will be missing two conditions. So for a determination of the arbitrary constants of the general solution of the Eulers Equation have to be obtained from the basic necessary condition for an extremum which is vanishing of the variation delta I.

(Refer Slide Time: 4:26)

Hence it follows that in the moving boundary value problem, an extremum is attained on solutions $y = y(x, c_1, c_2)$ of Euler's equation (2), c_1 and c_2 being arbitrary constants involved in the general solution of (2). Thus, we can consider the value of the functional only on functions of this family. Hence, the functional $I(y(x, c_1, c_2))$ is reduced to a function of the parameters c_1 and c_2 and of the limits of integration x_1 and x_2 .

Let us now consider the case when one of the boundary point (x_1, y_1) is fixed while the other boundary point can move and pass to the point $(x_2 + \delta x_2, y_2 + \delta y_2)$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

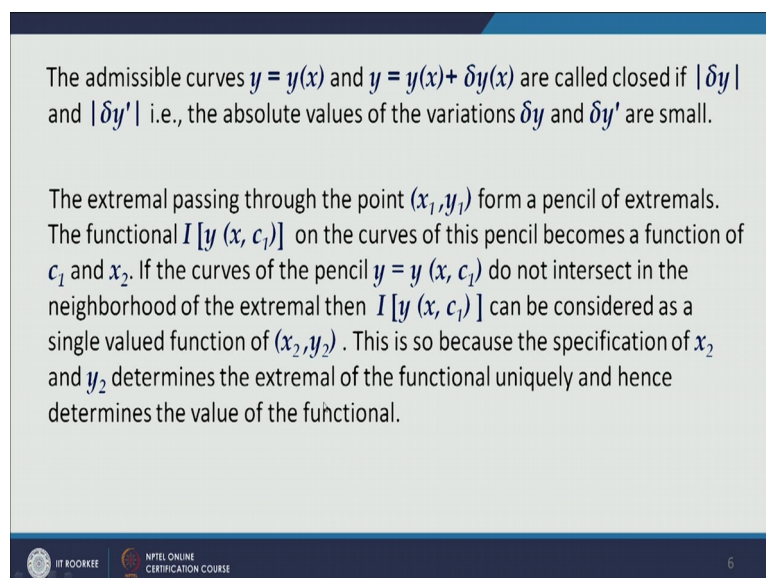

Now, hence it follows that in the moving boundary value problem an extremum is attained on solutions y equal to $y(x, c_1, c_2)$ of Euler's Equation the Euler's Equation is $F_y - d/dx F_{y'} = 0$ where c_1 and c_2 are arbitrary constants involved in the general solution of the Euler's Equation. Now so we can consider the value of the functional only on functions of the family y equal to $y(x, c_1, c_2)$.

Now here the functional $I[y(x, c_1, c_2)]$ is then a function of the parameters c_1 and c_2 and of the limits of the integration x_1 and x_2 . Now let us consider the case first we discuss a simple case where one of the boundary point x_1, y_1 is fixed while the other boundary point can move and pass to the point $x_2 + \delta x_2, y_2 + \delta y_2$.

(Refer Slide Time: 5:18)

The admissible curves $y = y(x)$ and $y = y(x) + \delta y(x)$ are called closed if $|\delta y|$ and $|\delta y'|$ i.e., the absolute values of the variations δy and $\delta y'$ are small.

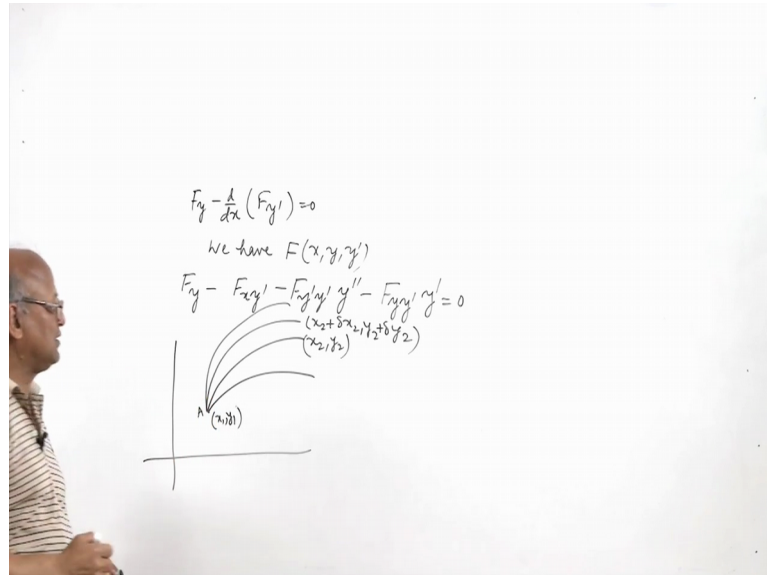

The extremal passing through the point (x_1, y_1) form a pencil of extremals. The functional $I[y(x, c_1)]$ on the curves of this pencil becomes a function of c_1 and x_2 . If the curves of the pencil $y = y(x, c_1)$ do not intersect in the neighborhood of the extremal then $I[y(x, c_1)]$ can be considered as a single valued function of (x_2, y_2) . This is so because the specification of x_2 and y_2 determines the extremal of the functional uniquely and hence determines the value of the functional.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

The admissible curves y equal to $y(x)$ and y equal to $y(x) + \delta y(x)$ will be called closed if $|\delta y|$ and $|\delta y'|$ are small. The extremal passing through the point (x_1, y_1) form a pencil of extremals.

(Refer Slide Time: 5:41)

You can see how it forms a pencil of extremals let us say this is our point $A(x_1, y_1)$ then we have a pencil of extremals. So this is (x_2, y_2) , this is $(x_2 + \delta x_2, y_2 + \delta y_2)$ we call it a pencil of curves because its shape is that of a pencil. Now so the extremal passing through the point (x_1, y_1) form a pencil of extremals.

(Refer Slide Time: 6:41)

The admissible curves $y = y(x)$ and $y = y(x) + \delta y(x)$ are called closed if $|\delta y|$ and $|\delta y'|$ i.e., the absolute values of the variations δy and $\delta y'$ are small.

The extremal passing through the point (x_1, y_1) form a pencil of extremals. The functional $I[y(x, c_1)]$ on the curves of this pencil becomes a function of c_1 and x_2 . If the curves of the pencil $y = y(x, c_1)$ do not intersect in the neighborhood of the extremal then $I[y(x, c_1)]$ can be considered as a single valued function of (x_2, y_2) . This is so because the specification of x_2 and y_2 determines the extremal of the functional uniquely and hence determines the value of the functional.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

Now the functional $I[y, x, c_1]$ on the curves of this pencil becomes a function of then c_1 and x_2 . If the curves of the family curves of the pencil y equal to $y(x, c_1)$ do not intersect in the neighborhood of the extremal then $I[y, x, c_1]$ can be considered as a single valued function of x_2, y_2 . This is because the specification x_2 and y_2 determines the extremal of the functional uniquely and hence determines the value of the functional.

(Refer Slide Time: 7:26)

Let us determine the variation of the functional $I[y(x, c_1)]$ when the boundary point moves from (x_2, y_2) to $(x_2 + \delta x_2, y_2 + \delta y_2)$.

Thus, the increment ΔI is given by

$$\begin{aligned} \Delta I &= I(y(x) + \delta y(x)) - I(y(x)) \\ &= \int_{x_1}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx - \int_{x_1}^{x_2} F(x, y, y') dx \\ &= \int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx \\ &\quad + \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx \quad \dots(3) \end{aligned}$$

Now let us determine the variation of the functional $I[y, x, c_1]$ when the boundary point moves from x_2, y_2 to $x_2 + \delta x_2, y_2 + \delta y_2$. So in this case the increment ΔI is then given by $\Delta I = I[y, x, c_1 + \delta y, x_2 + \delta x_2] - I[y, x, c_1]$ and $I[y, x, c_1 + \delta y, x_2 + \delta x_2]$ will then be integral x_1 to $x_2 + \delta x_2$ because we are moving from x_2, y_2 to $x_2 + \delta x_2, y_2 + \delta y_2$, so x_1 to $x_2 + \delta x_2$ $F(x, y + \delta y, y' + \delta y')$ dx and $I[y, x, c_1]$ will be x_1 to x_2 $F(x, y, y')$ dx . Now this is integral x_1 to $x_2 + \delta x_2$ can be written as integral x_1 to x_2 plus integral x_2 to $x_2 + \delta x_2$.

(Refer Slide Time: 8:14)

$$\begin{aligned}
 \Delta I &= I(y(x) + \delta y(x)) - I(y(x)) \\
 &= \int_{x_1}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx - \int_{x_1}^{x_2} F(x, y, y') dx \\
 &= \int_{x_1}^{x_2} F(x, y + \delta y, y' + \delta y') dx + \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx \\
 &\quad - \int_{x_1}^{x_2} F(x, y, y') dx \\
 &= \int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx + \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx
 \end{aligned}$$

We can write ΔI is equal to $I(y(x) + \delta y(x)) - I(y(x))$ which is equal to $\int_{x_1}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx - \int_{x_1}^{x_2} F(x, y, y') dx$. Now we can write it as $\int_{x_1}^{x_2} F(x, y + \delta y, y' + \delta y') dx + \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx - \int_{x_1}^{x_2} F(x, y, y') dx$ and this can be combined as $\int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx + \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx$.

So this is how we get the $\int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx + \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx$.

(Refer Slide Time: 11:00)

Using the mean value theorem, we have

$$\int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx = (F)_{x=x_2 + \theta \delta x_2} \cdot \delta x_2, \quad 0 < \theta < 1.$$

Since F is a continuous function, we may write

$$(F)_{x=x_2 + \theta \delta x_2} = F(x, y, y')_{x=x_2} + \varepsilon$$

where ε is an infinitesimal such that $\varepsilon \rightarrow 0$, as $\delta x_2 \rightarrow 0$ and $\delta y_2 \rightarrow 0$.

Thus,

$$\int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx = (F)_{x=x_2} \cdot \delta x_2 + \varepsilon \delta x_2.$$

Now let us use the mean value theorem, when we use the mean value theorem the second integral on the right x_2 to $x_2 + \delta x_2$ $F(x, y + \delta y, y' + \delta y')$ dx will be equal to the value of F calculated at x equal to $x_2 + \theta \delta x_2$ where θ is between 0 and 1, so this $x_2 + \theta \delta x_2$ is a point in between x_2 and $x_2 + \delta x_2$ into the length of the intervals. So this is δx_2 .

So using mean value theorem we can write the second integral on the right as F at x equal to $x_2 + \theta \delta x_2$ into δx_2 . Now we know that F is a continuous function, so we may write F at x equal to $x_2 + \theta \delta x_2$ is equal to $F(x, y, y')$ at x equal to x_2 plus ε , where ε is an infinitesimal such that ε goes to 0, as δx_2 goes to 0 and δy_2 goes to 0.

Thus we can write integral x_2 to $x_2 + \delta x_2$ as $F(x, y + \delta y, y' + \delta y')$ dx equal to F at x equal to x_2 into δx_2 plus $\varepsilon \delta x_2$. Let us put the value of this F at $x_2 + \theta \delta x_2$ here, so that we get this.

(Refer Slide Time: 12:30)

Using Taylor's theorem, the first term on the right hand side of (3) can be written as

$$\int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx$$

$$= \int_{x_1}^{x_2} \{F_y(x, y, y')\delta y + F_{y'}(x, y, y')\delta y'\} dx + R,$$

where R is an infinitesimal of the order higher than that of δy or $\delta y'$.

  9

Let us determine the variation of the functional $I[y(x, c_1)]$ when the boundary point moves from (x_2, y_2) to $(x_2 + \delta x_2, y_2 + \delta y_2)$.

Thus, the increment ΔI is given by

$$\Delta I = I(y(x) + \delta y(x)) - I(y(x))$$

$$= \int_{x_1}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx - \int_{x_1}^{x_2} F(x, y, y') dx$$

$$= \int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx$$

$$+ \int_{x_2}^{x_2 + \delta x_2} F(x, y + \delta y, y' + \delta y') dx \quad \dots(3)$$

  7

Now using Taylor's theorem the first term on the right side of this equation, equation number 3 is this one, this one. So this is the first term on the right side integral x_1 to x_2 $F(x, y + \delta y, y' + \delta y')$ minus $F(x, y, y')$.

Now this can be written as integral x_1 to x_2 $F_y(x, y, y')\delta y + F_{y'}(x, y, y')\delta y'$ dx plus R where R is an infinitesimal of the order higher than that of δy or $\delta y'$.

(Refer Slide Time: 13:22)

Handwritten derivation on a whiteboard:

$$\begin{aligned} \text{Thus, } \Delta(I) &= \int_{x_1}^{x_2} (F_{xy} \delta y + F_{yy} \delta y^2) dx + R + F|_{x=x_2} \delta x_2 + \epsilon \cdot \delta x_2 \\ &= \int_{x_1}^{x_2} F_{xy} \delta y dx + \int_{x_1}^{x_2} F_{yy} \delta y^2 dx + R + F|_{x=x_2} \cdot \delta x_2 + \epsilon \delta x_2 \\ &= \int_{x_1}^{x_2} F_{xy} \delta y' dx \\ &= \left\{ F_{xy} \delta y \right\}_{x_1}^{x_2} - \int_{x_1}^{x_2} \left(\frac{d}{dx} F_{xy} \right) \delta y dx \\ \text{Then } \Delta(I) &= \int_{x_1}^{x_2} \left(F_y - \frac{d}{dx} F_{xy} \right) \delta y dx + \left\{ F_y \delta y \right\}_{x_1}^{x_2} + (F)|_{x=x_2} \cdot \delta x_2 + \epsilon \delta x_2 + R \\ &= \left\{ F_y \delta y \right\}_{x_1}^{x_2} + \left\{ F \right\}_{x=x_2} \delta x_2 + \epsilon \delta x_2 + R \end{aligned}$$

Side notes on the right:

Since (x_1, y_1) is fixed
 $(\delta y)_{x=x_1} = 0$
 $\Delta I = (F_y)_{x=x_2} (\delta y)_{x=x_2} + (F)_{x=x_2} \delta x_2$

Now integral so what we will have the right hand side will become so thus this we have delta I equal to integral x 1 to x 2 F x, y plus delta y by Taylor's theorem we wrote it as derivative with respect to y F y into delta F x, y plus delta y, y dash plus delta y minus F x, y, y dash we wrote as F y delta y plus F y dash delta y dash. So F y delta y plus F y dash delta y dash dx plus R we wrote it as plus R where R is the infinitesimal and x 2 to x 2 plus delta x 2 we wrote as by using the mean value theorem we wrote it as F at x equal to x 2 into delta x 2 plus epsilon into delta x 2.

So we get the so let us now what we do is the let me integrate by parts so we can write it like this x 1 to x 2 F y delta y into dx plus integral x 1 to x 2 F y dash into delta y dash into dx plus R plus F at x equal to x 2 into delta x 2 plus epsilon into delta x 2. Now let us let us evaluate this integral if you evaluate integral x 1 to x 2 by integration by parts let us integrate by parts so we shall have F y dash into delta y minus d over dx of F y dash into delta y into dx.

Now so let us put this here so then delta I is equal to integral x 1 to x 2 F y integral x 1 to x 2 F y delta y delta x we can combine with this and write as F y minus d over dx F y dash into delta y dx. Then we have this one F y dash into delta y x 1 to x 2 and then we have F at x equal to x 2 into delta x 2 plus epsilon delta x 2, so this is what we have.

(Refer Slide Time: 17:18)

On integrating by parts, the linear part on the right side of the above integral is reduced to

$$\int_{x_1}^{x_2} F_y \delta y dx + (F_{y'} \delta y)_{x=x_1}^{x_2} - \int_{x_1}^{x_2} \frac{d}{dx} (F_{y'}) \delta y dx$$
$$= (F_{y'} \delta y)_{x=x_1}^{x_2} + \int_{x_1}^{x_2} \left(F_y - \frac{d}{dx} F_{y'} \right) \delta y dx .$$

Since the values of the functional I are taken only on the extremals, we have

$$F_y - \frac{d}{dx} F_{y'} = 0$$

  10

Now since the values of the functional are taken on the extremals therefore by the Euler's theorem we have $F_y - \frac{d}{dx} F_{y'}$ is equal to 0, so this expression becomes 0 and therefore this becomes $F_{y'} \delta y$ at x_1 to x_2 plus F at x equal to x_2 into δy plus $\epsilon \delta x$ and we also have R here.

Now now choose the boundary point x_1, y_1 is fixed δy at x_1, y_1 is equal to 0. So since x_1, y_1 point is fixed δy at x equal to x_1 is equal to 0 and thus the first expression on the right side becomes $F_{y'} \delta y$ at x equal to x_2 . So we and more over one ϵ goes to 0, one $\delta x_2, \delta y_2$ goes to 0 and R is also infinitesimally small. So we can write δI equal to δI equal to $F_{y'} \delta y$ at x equal to x_2 into δy at x equal to x_2 plus F at x equal to x_2 δx .

(Refer Slide Time: 19:27)

Further, the boundary point (x_1, y_1) is fixed, so

$$(\delta y)_{x=x_1} = 0.$$

Thus,
$$\int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx = (F_{y'} \delta y)_{x=x_2}.$$

Let us note that $(\delta y)_{x=x_2} \neq \delta y_2$, since δy_2 is the increment of the ordinate at the point is displaced from (x_2, y_2) to $(x_2 + \delta x_2, y_2 + \delta y_2)$. In fact, $(\delta y)_{x=x_2}$ is the increment of the ordinate at point $x = x_2$ when passing from the extremal joining (x_1, y_1) and (x_2, y_2) to the one joining (x_1, y_1) and $(x_2 + \delta x_2, y_2 + \delta y_2)$.

11

Now let us note that delta y at x equal to x 2 is not equal to delta y 2.

(Refer Slide Time: 19:38)

Note that $(\delta y)_{x=x_2} \neq \delta y_2$

Since (x_1, y_1) is fixed $(\delta y)_{x=x_1} = 0$

$$\delta I = (F_{y'})_{x=x_2} (\delta y)_{x=x_2} + (F)_{x=x_2} \delta x_2$$

So if we use that delta y note that this is not equal to delta y 2. What we do is let us see how it is not equal say this is your point A, this is your $x_2 + \delta x_2, y_2 + \delta y_2$, here is the point x_2, y_2 , this is your x_1, y_1 . Now so this is your point B let us say so now what we do is this is A, D, E let us take this as F and this as C.

Now since delta y 2 is the increment of y 2 when the boundary point is displaced from x_2, y_2 to $x_2 + \delta x_2, y_2 + \delta y_2$ in fact delta y at x equal to x_2 is the increment of the

ordinate at the point x equal to x_2 when passing from the extremal joining x_1, y_1 and x_2, y_2 to the one joining x_1, y_1 and $x_2 + \delta x_2, y_2 + \delta y_2$.

(Refer Slide Time: 21:28)

From the figure

$$BD = (\delta y)_{x=x_2}, \quad FC = \delta y_2.$$

Now, $EC \approx y'(x_2)\delta x_2$,

where \approx stands for "approximately equal to".

Then $BD = FC - EC$

$$\Rightarrow (\delta y)_{x=x_2} \approx \delta y_2 - y'(x_2)\delta x_2.$$

This equation is valid for the infinitesimals of higher order.

So BD is equal to δy , x equal to x_2 while FC is equal to δy_2 . So FC is δy_2 and now EC can be approximately equal to $y'(x_2)\delta x_2$ because this width is δx_2 , y' at x_2 is the slope of the curve $y(x)$ at x_2 , so approximately we can assume that EC is nothing but the slope of the curve at x_2 multiplied by the width DE that is δx_2 . So EC is approximately equal to δx_2 and therefore $BD = FC - EC$. So $BD = FC - EC$ and so this FC is equal to δy_2 so $\delta y_2 - y'(x_2)\delta x_2$. So BD is approximately equal to $\delta y_2 - y'(x_2)\delta x_2$. This equation is valid for the infinitesimals of higher order.

(Refer Slide Time: 23:08)

Thus,

$$\int_{x_1}^{x_2} \{F(x, y + \delta y, y' + \delta y') - F(x, y, y')\} dx \approx (F_{y'})_{x=x_2} (\delta y_2 - y'(x_2) \delta x_2)$$

Hence from (3) we have

$$\begin{aligned} \delta I &= (F)_{x=x_2} \delta x_2 + (F_{y'})_{x=x_2} (\delta y_2 - y'(x_2) \delta x_2) \\ &= (F - y' F_{y'})_{x=x_2} \delta x_2 + (F_{y'})_{x=x_2} \delta y_2. \end{aligned}$$

13

Now thus integral x 1 to x 2 F x, y plus delta y, y dash plus delta y dash minus F x, y, y dash dx which was equal to F y dash at x equal to x 2 into delta y at x equal to x 2, okay.

(Refer Slide Time: 23:22)

Note that $(\delta y)_{x=x_2} \neq \frac{\delta y}{\delta x}$

Since (x_1, y_1) is fixed $(\delta y)_{x=x_1} = 0$

$$\delta I = (F_{y'})_{x=x_2} (\delta y)_{x=x_2} + (F)_{x=x_2} \delta x_2$$

$$\Rightarrow \delta I = (F_{y'})_{x=x_2} (\delta y_2 - y'(x_2) \delta x_2) + (F)_{x=x_2} \delta x_2$$

Thus, $\delta I = (F - y' F_{y'})_{x=x_2} \delta x_2 + (F_{y'})_{x=x_2} \delta y_2$

This is so so thus delta I is equal to F y dash at x equal to x 2 into delta y at x equal to x 2 delta y at x equal to x 2 is approximately equal to delta y 2 so we have delta y 2 minus y dash x 2 delta x 2 plus F at x equal to x 2 delta x 2. This is this was equal to F at x equal to x 2 into delta x 2, yes. So we have now combined let us combine the two, so what we have? Delta I is equal to F minus y dash F minus y dash into delta x 2 plus F y dash at x equal to x 2 into delta y 2 F y dash into F y dash F y dash will also come here. So F minus y dash F y dash into delta x 2 plus F y dash at x equal to x 2 into delta y 2.

(Refer Slide Time: 25:30)

Case I: When the variation δx_2 and δy_2 are independent, the necessary condition for the extremum of (1) is

$$(F - y'F_{y'})_{x=x_2} = 0 \quad \text{and} \quad (F_{y'})_{x=x_2} = 0.$$

Case II: When the variation δx_2 and δy_2 are not independent, then

$\delta y_2 = \phi'(x_2)\delta x_2$ where $y = \phi(x)$ is the equation of the curve along which the boundary point (x_2, y_2) moves. In this case

$$\delta I = (F - y'F_{y'})_{x=x_2} \delta x_2 + (F_{y'})_{x=x_2} (\phi'(x_2)\delta x_2) = 0.$$

14

Now now let us discuss the 2 cases, 1 case is the case where the variations delta x 2 and delta y 2 are independent, the necessary then we apply the necessary condition for the extremum of the functional given by 1 so in that case F minus y dash F y dash if delta x 2 delta y 2 is equal to are independent of each other.

(Refer Slide Time: 25:48)

Note that $(\delta y)_{x=x_2} \neq \delta y_2$

$\delta I = 0$ is the necessary condition for extremum of I

$F - y'F_{y'} = 0$
 $F_{y'}|_{x=x_2} = 0$
 when δx_2 and δy_2 are independent

Since (x_1, y_1) is fixed
 $(\delta y)_{x=x_1} = 0$

$\delta I = (F_{y'})_{x=x_2} (\delta y)_{x=x_2} + (F)_{x=x_2} \delta x_2$

$\Rightarrow \delta I = (F_{y'})_{x=x_2} (\delta y_2 - y'(x_2)\delta x_2) + (F)_{x=x_2} \delta x_2$

EC = $y'(x_2)\delta x_2$
 BD = EF = FC - EC
 $(\delta y)_{x=x_2} \approx \delta y_2 - y'(x_2)\delta x_2$

Thus, $\delta I = (F - y'F_{y'})_{x=x_2} \delta x_2 + (F_{y'})_{x=x_2} \delta y_2$

Then delta I equal to 0 will give us F minus y dash F y dash is equal to 0 because the condition for the extremum is delta I equal to 0 this is the necessary condition for the extremum. So if delta x 2, delta y 2 are independent we have F minus y dash F y dash equal to 0 at x equal to x 2 and we also have F y dash at x equal to x 2 equal to 0 when delta x 2, delta y 2 are independent, so this case 1.

(Refer Slide Time: 26:52)

Case I: When the variation δx_2 and δy_2 are independent, the necessary condition for the extremum of (1) is

$$(F - y'F_{y'})_{x=x_2} = 0 \quad \text{and} \quad (F_{y'})_{x=x_2} = 0.$$

Case II: When the variation δx_2 and δy_2 are not independent, then

$\delta y_2 = \phi'(x_2)\delta x_2$ where $y = \phi(x)$ is the equation of the curve along which the boundary point (x_2, y_2) moves. In this case

$$\delta I = (F - y'F_{y'})_{x=x_2} \delta x_2 + (F_{y'})_{x=x_2} (\phi'(x_2)\delta x_2) = 0.$$

14

In the case 2 when the variation δx_2 and δy_2 are not independent in that case we can write δy_2 equal to $\phi'(x_2)\delta x_2$ where $y = \phi(x)$ is the equation of the curve along which the boundary point x_2, y_2 moves.

(Refer Slide Time: 27:16)

When δx_2 and δy_2 are not independent

$\delta y_2 = \phi'(x_2)\delta x_2$

we shall have

$$\delta I = (F - y'F_{y'})_{x=x_2} \delta x_2 + F_{y'}|_{x=x_2} \delta y_2$$

$$= (F - y'F_{y'})_{x=x_2} \delta x_2 + F_{y'}|_{x=x_2} \phi'(x_2)\delta x_2$$

$$= [F + (\phi' - y')F_{y'}]_{x=x_2} \delta x_2 = 0$$

Since δx_2 is arbitrary, we get

$$[F + (\phi' - y')F_{y'}]_{x=x_2} = 0$$

So in this case δI will be equal to 0, so when δx_2 and δy_2 are not independent. So in this case in this case δy_2 will be equal to $\phi'(x_2)\delta x_2$ and we therefore will have so we shall have δI δI was equal to $F - y'$ dash into $F_{y'}$ dash at x equal to x_2 δx_2 plus $F_{y'}$ dash at x equal to x_2 into δy_2 this will be changed to $F - y'$ dash $F_{y'}$ dash at x equal to x_2 into δx_2 plus $F_{y'}$ dash at x equal to x_2 , δy_2 will be

replaced by $\phi(x_2) \delta x_2$ and we can combine the term to two terms and we write $(F + \phi' y - y' F_y)$ at $x = x_2$ equal to $x_2 \delta x_2$ equal to 0.

So since δx_2 is arbitrary we shall have so since δx_2 is arbitrary we get $F + \phi' y - y' F_y$ at $x = x_2$ is equal to 0. So this condition is to be satisfied at the point x_2, y_2 and this condition is known as the transversality condition.

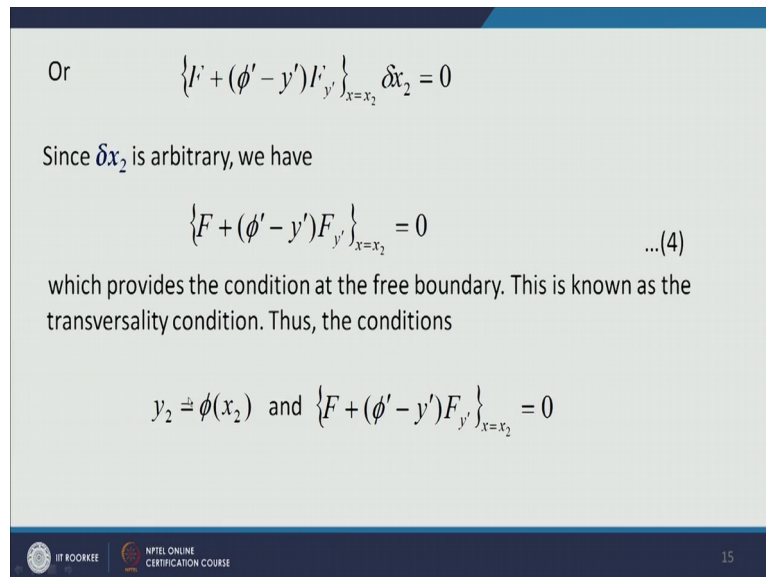

(Refer Slide Time: 29:56)

Or
$$\left\{ F + (\phi' - y') F_{y'} \right\}_{x=x_2} \delta x_2 = 0$$

Since δx_2 is arbitrary, we have

$$\left\{ F + (\phi' - y') F_{y'} \right\}_{x=x_2} = 0 \quad \dots(4)$$

which provides the condition at the free boundary. This is known as the transversality condition. Thus, the conditions

$$y_2 = \phi(x_2) \quad \text{and} \quad \left\{ F + (\phi' - y') F_{y'} \right\}_{x=x_2} = 0$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

So thus we have two conditions $y_2 = \phi(x_2)$ because x_2, y_2 point lies on the curve $y = \phi(x)$ and the transversality condition which is $F + \phi' y - y' F_y$ at $x = x_2$ is equal to 0.

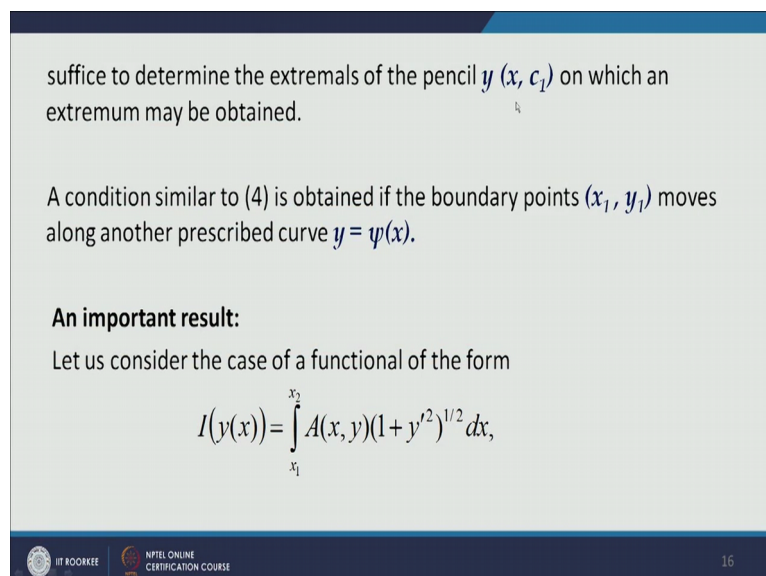

(Refer Slide Time: 30:22)

suffice to determine the extremals of the pencil $y(x, c_1)$ on which an extremum may be obtained.

A condition similar to (4) is obtained if the boundary points (x_1, y_1) moves along another prescribed curve $y = \psi(x)$.

An important result:

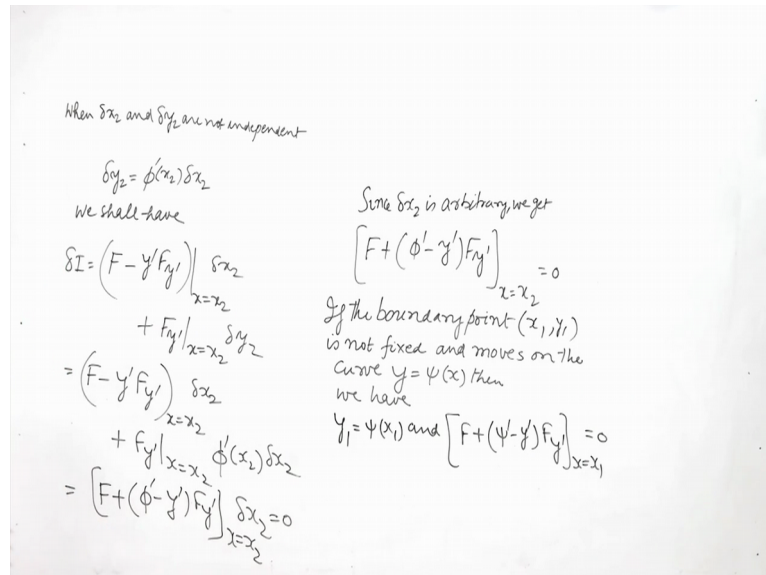

Let us consider the case of a functional of the form

$$I(y(x)) = \int_{x_1}^{x_2} A(x, y) (1 + y'^2)^{1/2} dx,$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 16

Now these two conditions are sufficient to determine the extremals of the pencil $y, x, c, 1$ on which an extremum may be obtained. Now in case the boundary point x_1, y_1 is not fixed it moves on the curve y equal to Ψx then a condition similar to the transversality condition can be derived in a similar manner.

(Refer Slide Time: 30:47)

And if we have y equal to Ψx then we shall have the if the boundary point if the boundary point x_1, y_1 is not fixed but moves is not fixed and moves on the curve y equal to Ψx then we have y_1 equal to Ψx_1 and the transversality condition F plus Ψ dash minus y dash $F y$ dash at x equal to x_1 equal to 0 they can be derived this can be derived in a similar manner.

(Refer Slide Time: 32:10)

suffice to determine the extremals of the pencil $y(x, c_1)$ on which an extremum may be obtained.

A condition similar to (4) is obtained if the boundary points (x_1, y_1) moves along another prescribed curve $y = \psi(x)$.

An important result:

Let us consider the case of a functional of the form

$$I(y(x)) = \int_{x_1}^{x_2} A(x, y)(1 + y'^2)^{1/2} dx,$$

16

So now let us discuss an important result suppose that we have a functional of the form $\int_{x_1}^{x_2} A(x, y) \sqrt{1 + y'^2} dx$.

(Refer Slide Time: 32:20)

$$\text{Here } F(x, y, y') = A(x, y) \sqrt{1 + y'^2}$$

$$\frac{\partial F}{\partial y'} = A(x, y) \frac{y'}{\sqrt{1 + y'^2}}$$

$$\text{In this case, the transversality condition}$$

$$\left[F + (\phi' - y') F_{y'} \right]_{x=x_2} = 0$$

$$\Rightarrow \left[A(x, y) \sqrt{1 + y'^2} + (\phi' - y') \frac{A(x, y) y'}{\sqrt{1 + y'^2}} \right]_{x=x_2} = 0$$

$$\text{or } \left[A(x, y) \left\{ (1 + y'^2) + (\phi' - y') y' \right\} \right]_{x=x_2} = 0$$

$$\left[A(x, y) (\phi' y' + 1) \right]_{x=x_2} = 0$$

$$\text{Since } A(x, y) \neq 0, \text{ we have } (\phi' y' + 1)_{x=x_2} = 0$$

$$\text{or } y' = -\frac{1}{\phi'} \text{ at } x = x_2$$

So here $F(x, y, y')$ is equal to $A(x, y) \sqrt{1 + y'^2}$ and we assume that $A(x, y)$ does not vanish so then let us find the partial derivative of this with respect to y' . So what we will get $A(x, y) \frac{y'}{\sqrt{1 + y'^2}}$.

So in this case the transversality condition at $x = x_2$ gives this will imply that we have $F + (\phi' - y') F_{y'}$ is equal to 0 at $x = x_2$. So $F_{y'}$ is $A(x, y) \frac{y'}{\sqrt{1 + y'^2}}$ and we will have $(\phi' - y') \frac{A(x, y) y'}{\sqrt{1 + y'^2}}$ plus $A(x, y) \sqrt{1 + y'^2}$ at $x = x_2$ equal to 0. Since $A(x, y) \neq 0$ we have $(\phi' - y') \frac{y'}{\sqrt{1 + y'^2}} + \sqrt{1 + y'^2} = 0$ at $x = x_2$. This means that the extremal curve c which is $y = y(x)$ is orthogonal to the curve $y = \phi(x)$ on which the point (x_2, y_2) moves.

Now what we will get here $(\phi' - y') \frac{y'}{\sqrt{1 + y'^2}} + \sqrt{1 + y'^2} = 0$ at $x = x_2$. But $A(x, y)$ is not equal to 0 since $A(x, y)$ does not vanish we have $(\phi' - y') \frac{y'}{\sqrt{1 + y'^2}} + \sqrt{1 + y'^2} = 0$ at $x = x_2$ or we can say $(\phi' - y') y' + (1 + y'^2) = 0$ at $x = x_2$. This means that the extremal curve c which is $y = y(x)$ is orthogonal to the curve $y = \phi(x)$ on which the point (x_2, y_2) moves.

So this is the case where the curve the extremizing curve y equal to $y = x$ and the curve y equal to $\phi(x)$ on which the point (x, y) moves they are orthogonal at the point (x, y) , x equal to x , y equal to y . So this is the orthogonality condition. So this is a special case where $F(x, y, y')$ is of a particular form, it is $A(x, y) \sqrt{1 + y'^2}$ where we assume that (x, y) is not equal to 0. So with this I would like to conclude my lecture, thank you very much.
