Fredholm Integral Equation with Separable Kernels: Examples

Hello Friends! Welcome to this lecture, in previous class we have already seen the theory to solve Fredholm Integral Equation with Separable Kernel and we have also discussed the concept of Eigen values and Eigen functions. And now in this lecture we discuss some example based on that theory given earlier. So let us go to the first example here.

(Refer Slide Time: 00:50)

Here I just want to note here that in previous class we have discussed $y(x)$ equal to $f(x)$ plus a to b and $k(x, t)$ and $f(t)$ dt sorry here it is $f(t)$ it is $y(t)$ here, $y(t)$ dt here. And here we have assumed that this kernel $k(x, t)$ is separable means we have assumed that it can be written as in this separable form are equal to 1 to n . And we have discussed how to solve this.

(Refer Slide Time: 01:33)

Example 1

Solve the Fredholm integral equation of the second kind

$$y(x) = x + \lambda \int_0^1 (xt^2 + x^2t)y(t)dt. \quad (1)$$

Solution: The kernel $k(x, t) = xt^2 + x^2t$ is separable and we can set

$$c_1 = \int_0^1 t^2 y(t)dt, \quad c_2 = \int_0^1 ty(t)dt.$$

The (1) becomes

$$y(x) = x + \lambda c_1 x + \lambda c_2 x^2.$$

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So let us take the first example given here and here the example is that solve the Fredholm Integral Equation of the second kind $y(x)$ equal to x plus λ 0 to 1 xt^2 plus x^2t $y(t) dt$. So here if you look at kernel is this $x t^2$ plus $x^2 t$.

So it is here $x t^2$ is written as the function of x and function of t^2 plus this also can be written as function of x and function of t . So this is of the separable kind. So here the kernel $k(x, t)$ is a separable and now we can use our theory which we have already discussed to solve this.

(Refer Slide Time: 02:11)

$$y(x) = f(x) + \lambda \int_a^b K(x,t) y(t) dt.$$

$$K(x,t) = \sum_{i=1}^n q_i(x) b_i(t).$$

$$y(x) = x + \lambda \int_0^1 (xt^2 + x^2t)y(t) dt$$

$$= x + \lambda x \int_0^1 t^2 y(t) dt + \lambda x^2 \int_0^1 t y(t) dt$$

$$= x + \lambda x c_1 + \lambda x^2 c_2.$$

$$t + \lambda c_1 t + \lambda t^2 c_2.$$

$$t^2 [t + \lambda c_1 t + \lambda t^2 c_2] dt$$

So here what we trying to do here, just I am going to write it here so in this example $y(x)$ is equal to x plus λ $\int_0^1 x t^2 dx$ and $y(t) dt$ I can simplify this as x plus λ . Now x say here variable is t so I can take x out so it is $\int_0^1 t^2 y(t) dt$ plus λ . I can take x square here so $\lambda \int_0^1 y(t) dt$.

So if you look at this quantity is going to be a constant quantity. So I am going to write it x plus λ $\int_0^1 y(t) dt$ if I denote this as say c_1 then it is c_1 plus λ $\int_0^1 y(t) dt$ again the same this quantity is also constant so I will write it like C_2 . So here if I denote this c_1 as $\int_0^1 y(t) dt$ and C_2 as $\int_0^1 y(t) dt$. And I can write equation 1 as $y(x)$ equal to x plus λc_1 plus $\lambda c_2 x^2$.

So it means that solution is given like this only thing we have to discuss here how to find out the value c_1 and c_2 the constant c_1 and c_2 . For this what we can do here we can look at the formula here C_1 is equal to $\int_0^1 y(t) dt$. Now we already know what is the form of $y(t)$ I can write down I can use this $y(x)$ equal to this to put it here. So when you put let me write it here.

So here this is your $y(x)$ so I can write $y(t)$ as t plus λc_1 plus $\lambda c_2 t^2$ this x is t square so this is $\lambda c_2 t^2$. So using this I can write it here C_1 as $\int_0^1 t^2 (t + \lambda c_1 + \lambda c_2 t^2) dt$ and we can solve this. So similarly we can do for C_2 also.

(Refer Slide Time: 04:40)

On putting this value in c_1 and c_2 , we obtain

$$c_1 = \frac{1}{4} + \frac{1}{4}\lambda c_1 + \frac{1}{5}\lambda c_2.$$

$$c_2 = \frac{1}{3} + \frac{1}{3}\lambda c_1 + \frac{1}{4}\lambda c_2.$$

Now, after finding the value of c_1 and c_2 , we find the solution

$$y(x) = \frac{[(240 - 60\lambda)x + 80\lambda x^2]}{(240 - 120\lambda - \lambda^2)}.$$

IT ROADSHOW | NPTEL ONLINE CERTIFICATION COURSE | 3

So if we use this then I can write c_1 as $\frac{1}{4} + \frac{1}{4}\lambda c_1 + \frac{1}{5}\lambda c_2$. Similarly we can have expression for c_2 . Now if you look at this is a simple algebraic

So here I am writing here $y(x)$ if you take that sides then it is $\lambda \int_0^1 (3x - 2) y(t) dt$ (06:09). So now here if you write it then it is λ you can take $3x - 2$ out because variable the integration is t so $\int_0^1 (3t - 2) y(t) dt$ and that is given as $y(x)$, ok.

Now this quantity is going to be a constant call it c then we have $y(x)$ is equal to $c \lambda (3x - 2)$. So now our form of the solution is already known to us that $y(x)$ is equal to $c \lambda (3x - 2)$.

The only thing we need to find out is the constant c here. So here we have denoted c as $\int_0^1 y(t) dt$. So here if you write down then c is going to be $\int_0^1 y(t) dt$ now $y(t)$ is going to be what $c \lambda$ in place of x we are writing t here $3t - 2$ dt . So if you look at this is what $\int_0^1 c \lambda (3t - 2) dt$ you can take it out then it is what $3t^2 - 2t$ and dt .

And if you solve you will get $c \lambda c \lambda$ and this is what $3t^2 - 2t$ by $3 - 3$ is there $-2t^2 + 2t$ and if you use a integral boundary limit, boundary 0 to 1 then it is coming out to be $1 - 1$ that is 0 . So this is coming out to be 0 . So here we have c equal to 0 . So it means that if you use c equal to 0 here then our solution is going to be $y(x)$ is equal to 0 . It means that here the solution of this homogeneous problem is nothing but trivial solution.

So if I look at this problem as Eigen value Eigen function problem then this homogeneous Fredholm integral equation is not having any Eigen value because we do not have any non trivial solution corresponding to any λ here. So and it is not very surprising because if you look at the kernel here, kernel is $3x - 2$ and t . So kernel is not symmetric and we can say that a Fredholm integral equation with non symmetric kernel may not have Eigen value and Eigen function.

(Refer Slide Time: 08:50)

So but if you look at the same problem this problem in a different manner, so if I look at this problem as $y(x)$ is equal to $\lambda \int_0^1 (2x-3)t y(t) dt$. So here if you look at your kernel is again in separable kind and kernel is also not symmetric. So I can say that here symmetric means $k(x, t)$ is not equal to $k(t, x)$. I am talking about a real kernels so I am writing $k(x, t)$ is not equal to $k(t,x)$.

So it is a problem with non symmetric kernel but if you try to solve the same problem I am using the same technique I can write it $y(x)$ is equal to $\lambda \int_0^1 (2x-3)t y(t) dt$ I can write this as $C \int_0^1 (2t-3)t y(t) dt$ I can write this as $C \int_0^1 (2t^2 - 3t) dt$ and this is what $\lambda C \int_0^1 (2t^2 - 3t) dt$.

So this I can write it here $\lambda C \int_0^1 (2t^2 - 3t) dt$ and if you simplify this is $\lambda C [2t^3/3 - 3t^2/2]_0^1$ and here you get $\lambda C [2/3 - 3/2]$. So if you simplify you will get $\lambda C [4/6 - 9/6]$ and this is what $\lambda C [-5/6]$ and you can simplify and you can get value for this I can say that $C [1 + 15/6] = 0$ and this expression is what $C [1 - 15/6] = 0$ so it is going to be plus 5 by 6, so it is equal to 0.

So here if I take C equal to 0 then we are getting a trivial solution but if I take $\lambda = -6/5$ then we can say that λ is going to be minus 6 by 5 then in this case I can chose any value of C or I can say that in this case when λ is equal to minus 6 by 5

then our solution $y(x)$ is given by $c_1 \lambda$, λ is minus 6 by 5 so I can write it minus 6 by 5 here, this value to x minus 3.

So in this particular case we too have non symmetric kernel but in this particular case we have Eigen values because corresponding solution is non zero solution. So here we can relate these two problems as that a non symmetric Fredholm integral equation with non symmetric kernel may or may not have Eigen value, ok. So so here we have solved these two problems with the help of separable kernel, ok. So this is what we have discussed now.

(Refer Slide Time: 12:00)

The slide, titled "Example 3", presents a Fredholm integral equation of the second kind. It states: "Consider the differential equation" (though it is an integral equation)
$$y(x) = \lambda \int_0^1 (1 - 3xt)y(t)dt + F(x). \quad (5)$$
 This equation can be written in the form
$$y(x) = \lambda(c_1 - 3c_2x) + F(x). \quad (6)$$
 where $c_1 = \int_0^1 y(t)dt$ and $c_2 = \int_0^1 ty(t)dt$
$$(7)$$
 The slide footer includes the IIT Roorkee logo and the text "NPTEL ONLINE CERTIFICATION COURSE" with the number "6" in the bottom right corner.

Now let us go to example 3 here, so here we want to solve this Fredholm integral equation of second kind so $y(x)$ is given as $\lambda \int_0^1 (1 - 3xt)y(t) dt + f(x)$. If you look at here kernel is symmetric, ok. So $k(x, t)$ is basically $1 - 3xt$ so $k(x, t)$ is same as $k(t, x)$. Now you also want to solve this particular problem.

(Refer Slide Time: 12:29)

$$y(x) = F(x) + \lambda \int_0^1 (1-3xt) y(t) dt$$

$$K(x,t) = 1-3xt$$

$$= 1-3x.t$$

$$= F(x) + \lambda \int_0^1 y(t) dt - \lambda x \int_0^1 t y(t) dt$$

$$C_1 = \int_0^1 y(t) dt, C_2 = \int_0^1 t y(t) dt$$

$$y(x) = F(x) + \lambda C_1 - 3x \lambda C_2$$

$$y(x) = F(x) + \lambda (C_1 - 3x C_2)$$

Let me write it here ok, so problem is this $y(x)$ I am writing $f(x)$ here plus lambda times 0 to 1 (1 minus 3x t) and $y(t)$ dt here. So here your $k(x, t)$ is written as (1 minus 3xt) which I can write it 1 minus 3 times x times t. So I can write it that it is a function of x it is function of t so it is separable kind and if you simplify this further then it is $f(x)$ plus lambda 0 to 1 $y(t)$ dt plus you can write it here as minus lambda 0 to 1 3x you can take it out.

So 3x also you can take it out here and it is what t $y(t)$ dt. So again as we have pointed out this is going to be a constant function call it c_1 and this is 0 to 1 t $y(t)$ dt is your c_2 . So c_1 is going to be 0 to 1 $y(t)$ dt and c_2 is going to be 0 to 1 tof $y(t)$ dt. So with this our solution $y(x)$ can be written as $f(x)$ plus lambda c_1 minus 3x lambda c_2 . Or I can simplify this further $f(x)$ plus lambda you can take it out $c_1 (1 - 3x) c_2$. So only thing we need to find out these constants c_1 and c_2 .

(Refer Slide Time: 14:27)

Multiplying both sides of (6) successively by 1 and x and integrate the result over (0, 1), we get

$$c_1 = \lambda(c_1 - \frac{3}{2}c_2) + \int_0^1 F(x)dx,$$
$$c_2 = \lambda(\frac{1}{2}c_1 - c_2) + \int_0^1 xF(x)dx.$$

or

$$(1 - \lambda)c_1 + \frac{3}{2}\lambda c_2 = \int_0^1 F(x)dx,$$
$$-\frac{1}{2}\lambda c_1 + (1 + \lambda)c_2 = \int_0^1 xF(x)dx. \quad (8)$$

The determinant of coefficients is given by

$$D(\lambda) = \frac{1}{4}(4 - \lambda^2) \quad (9)$$

IT ROORKEE
NPTEL ONLINE
CERTIFICATION COURSE
7

So to find out this what we try to do here, you can use this thing. So what we try to do here look at the (question) equation number 6 here we multiply by 1 and integrate between 0 to 1. So if you look at the equation number 6 multiply by 1 with no change and integrate between 0 to 1. So this side will give you c 1 and this i you will get something which we want to integrate here. So that will give you 1 equation in terms of C 1.

And similarly if you multiply this with respect to x here and integrate between 0 to 1 then we can get c 2 here, so multiplying both side of 6 successfully by 1 and x and (integral) indicate the result over 0 to 1 we can get these two equations. So first equation is this c 1 equal to lambda c 1 minus 3 by 2 c 2 plus 0 to 1 f(x) dx and c 2 equal to lambda c 1 by 2 minus c 2 plus 0 to 1 x f(x) dx.

And if you simplify this then you will have an algebraic equation in terms of c 1 and c 2 so if you look at this is coefficient matrix I can represent as a d lambda so I am just going to write it equation number 8 here.

(Refer Slide Time: 15:49)

$$(1-\lambda)C_1 + \frac{3}{2}\lambda C_2 = \int_0^1 f(x) dx$$

$$-\frac{\lambda}{2}C_1 + (1+\lambda)C_2 = \int_0^1 x f(x) dx$$

$$\begin{pmatrix} 1-\lambda & \frac{3}{2}\lambda \\ -\frac{\lambda}{2} & 1+\lambda \end{pmatrix} \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = \begin{pmatrix} \int_0^1 f(x) dx \\ \int_0^1 x f(x) dx \end{pmatrix}$$

$$D(\lambda) = 1 - \lambda^2 + \frac{3}{4}\lambda^2$$

$$= \frac{1}{4}(4 - \lambda^2)$$

So if you look at $1 - \lambda C_1 + \frac{3}{2}\lambda C_2$ is equal to $\int_0^1 f(x) dx$ plus here it is second equation is $-\frac{\lambda}{2}C_1 + (1 + \lambda)C_2$ equal to $\int_0^1 x f(x) dx$.

So here your lambda coefficient matrix is given by $1 - \lambda$ and $\frac{3}{2}\lambda$ minus λ by 2 and $1 + \lambda$ here. So this is a coefficient matrix here and C_1 and C_2 and it is given by this thing. Here it is $\int_0^1 f(x) dx$ and $\int_0^1 x f(x) dx$.

Now to solve this look at the determinant of this coefficient matrix so $D(\lambda)$ is basically $1 - \lambda^2 + \frac{3}{4}\lambda^2$ (squa) $\frac{3}{4}\lambda^2$ by 4 lambda square. So I can write it here that this is going to be $\frac{1}{4}(4 - \lambda^2)$ is that ok.

Now so here solution on this algebraic equation will depend on the quantity lambda that $D(\lambda)$ is 0 and $D(\lambda)$ is not equal to 0 . So here we consider the case that if lambda is not equal to plus minus 2 means this $D(\lambda)$ is non zero. In that case we have a unique solution and we can get that unique solution by solving this algebraic equation.

(Refer Slide Time: 17:36)

It follows that a unique solution exists if and only if

$$\lambda \neq \pm 2, \quad (10)$$

which is obtained by solving (8), for c_1 and c_2 and putting the result into (6). In particular,

- if $F(x) = 0$ and $\lambda \neq \pm 2$, the only solution is the trivial solution $y(x) = 0$.
- The $\lambda = \pm 2$ are the eigen values of the problem. If $\lambda = +2$, equations (8) takes the form

$$\begin{aligned} -c_1 + 3c_2 &= \int_0^1 F(x) dx, \\ -c_1 + 3c_2 &= \int_0^1 xF(x) dx. \end{aligned} \quad (11)$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

So you can get c_1 and c_2 by just inverting this non singular matrix and you can get values of c_1 and c_2 . Once we have c_1 and c_2 we can write down our solution $y(x)$ in terms of c_1 and c_2 . So now here there are certain cases depending on the $f(x)$ and the value is λ here. If I assume that $f(x)$ equal to 0 and λ is not equal to plus minus 2.

So when we assume that λ is not equal to plus minus 2 means coefficient matrix is non singular matrix. So in that case our $f(x)$ equal to 0 means we have a homogeneous equation.

So homogenous Fredholm integral equation is given with the thing that coefficient matrix has is a non singular matrix. So in this particular case the value here if you look at the value here c_1 and c_2 is going to be what. So here this is $f(x)$ is 0 so this is going to be 0 0 and this is a non singular matrix so you can get only a trivial solution that c_1 equal to 0 and c_2 equal to 0.

(Refer Slide Time: 18:41)

It follows that a unique solution exists if and only if

$$\lambda \neq \pm 2, \quad (10)$$

which is obtained by solving (8), for c_1 and c_2 and putting the result into (6). In particular,

- if $F(x) = 0$ and $\lambda \neq \pm 2$, the only solution is the trivial solution $y(x) = 0$.
- The $\lambda = \pm 2$ are the eigen values of the problem. If $\lambda = +2$, equations (8) takes the form

$$\begin{aligned} -c_1 + 3c_2 &= \int_0^1 F(x) dx, \\ -c_1 + 3c_2 &= \int_0^1 xF(x) dx. \end{aligned} \quad (11)$$

NPTEL ONLINE CERTIFICATION COURSE

So I can say that when $f(x)$ is equal to 0 I can simplify this result as this, if $f(x)$ is not $f(x)$ equal to 0 and λ is not equal to plus minus 2 the only solution is the trivial solution $y(x)$ equal to 0. But if I assume that λ is plus minus 2 and then the coefficient matrix is going to be a singular matrix. So I can find out the Eigen values of the our problem.

(Refer Slide Time: 19:14)

$$\begin{aligned} (1-\lambda)c_1 + \frac{\lambda}{2}c_2 &= \int_0^1 F(x) dx \\ -\frac{\lambda}{2}c_1 + (1+\lambda)c_2 &= \int_0^1 xF(x) dx \end{aligned}$$

$$\begin{pmatrix} 1-\lambda & \frac{\lambda}{2} \\ -\frac{\lambda}{2} & 1+\lambda \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \begin{pmatrix} \int_0^1 F(x) dx \\ \int_0^1 xF(x) dx \end{pmatrix}$$

$$\begin{aligned} D(\lambda) &= 1-\lambda^2 + \frac{3}{4}\lambda^2 \\ &= \frac{1}{4}(4-\lambda^2) \end{aligned}$$

So here we can say that $D(\lambda) = 0$ gives you the values for Eigen values. So here $\lambda = \pm 2$ gives you Eigen values of the problem.

(Refer Slide Time: 19:25)

• If $\lambda = -2$, equations (8) takes the form

$$c_1 - c_2 = \frac{1}{3} \int_0^1 F(x) dx.$$
$$c_1 - c_2 = \int_0^1 xF(x) dx. \quad (12)$$

Equation (11) is compatible only if the function $F(x)$ satisfies the condition

$$\int_0^1 F(x) dx = \int_0^1 xF(x) dx \text{ or } \int_0^1 (1-x)F(x) dx = 0. \quad (13)$$

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Now we look at the particular case when lambda is equal to plus 2. So when lambda is equal to plus 2 then your equation this equation, equation number 8 here you put lambda equal to 2 then this will reduce to equation number 11 which says that minus c 1 plus 3c 2 equal to 0 to 1 f(x)dx.

And if you look at the second equation it is also minus c 1 plus 3 c 2 equal to 0 to 1 f(x) dx. Now these two equation will be valid only when the value of 0 to 1 f(x)dx is same as 0 to 1 x f(x) dx. Or I can say that, that this equation number 11 is compatible if 0 to 1 f(x) dx is equal to 0 to 1 x f(x) dx. So we will discuss this case.

Now let us move to case lambda equal to minus 2. In this case when lambda equal to minus 2 equation 8 means this equation, equation number 8 is reduced to this form c 1 minus c 2 equal to 1 by 3 0 to 1 f(x) dx and c 1 minus c 2 equal to 0 to 1 x f(x) dx. So again here we have a c 1 minus c 2 equal to this and c 1 minus c 2 equal to this. This is possible only when the right hand side of these two equations match.

So I can say that this equation number 11 which is corresponding to lambda equal to plus 2 and equation number 12 which is corresponding to lambda equal to minus 2 will be compatible if the right hand side of this equation number 11 and equation 12 should match. So I can write that equation 11 is compatible only if the function f(x) satisfy the condition this. So here equation number 11 is given here, so this will be compatible if these two are equal.

Or I can say that $\int_0^1 f(x) dx$ equal to $\int_0^1 x f(x) dx$ or you can say $\int_0^1 (1-x) f(x) dx$ equal to 0. So here if $f(x)$ satisfies this condition then only equation number 11 makes sense.

(Refer Slide Time: 21:38)

Similarly (12) is compatible only when

$$\frac{1}{3} \int_0^1 F(x) dx = \int_0^1 xF(x) dx \quad \text{or} \quad \int_0^1 (1-3x)F(x) dx = 0. \quad (14)$$

in each of the above cases the corresponding equations (11) and (12) are redundant.
First let us consider the case when

$$F(x) = 0. \quad (15)$$

so that (5) is homogeneous. Then if $\lambda \neq \pm 2$, the only solution is the trivial solution.

- If $\lambda = 2$, equation (11) is redundant and gives $c_1 = 3c_2$. Thus in this case (6) gives the solution

$$y(x) = A(1-x) \quad \text{when} \quad \lambda = 2 \quad (16)$$

$A = 6c_2$ is an arbitrary constant. The function $(1-x)$ and all its non-zero multiples are the eigen function corresponding to the eigen value $\lambda = +2$.

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 10

Similarly when λ equal to minus 2 is compatible only when these two things are equal or I can say that $\int_0^1 (1-3x) f(x) dx$ is equal to 0. So it means that when λ is equal to 2 then equation will give a makes sense. If $\int_0^1 (1-x) f(x) dx$ is equal to 0.

Similarly when λ equal to minus 2. You can calculate c_1 and c_2 only when we have $\int_0^1 (1-3x) f(x) dx$ is 0. So let us sarize everything. We can say that if I consider $f(x)$ equal to 0 r λ is plus minus not equal to plus minus 2. We have seen that only solution is trivial solution. But if you take λ equal to 2 then equation 11 is redundant.

(Refer Slide Time: 22:25)

It follows that a unique solution exists if and only if

$$\lambda \neq \pm 2, \quad (10)$$

which is obtained by solving (8), for c_1 and c_2 and putting the result into (6). In particular,

- if $F(x) = 0$ and $\lambda \neq \pm 2$, the only solution is the trivial solution $y(x) = 0$.
- The $\lambda = \pm 2$ are the eigen values of the problem. If $\lambda = +2$, equations (8) takes the form

$$-c_1 + 3c_2 = \int_0^1 F(x) dx,$$

$$-c_1 + 3c_2 = \int_0^1 xF(x) dx. \quad (11)$$

IT FRODOOEE NPTEL ONLINE CERTIFICATION COURSE 8

If you look at equation number 11 these two will give the same things redundant it will make sense only when we have 0 to 1 (1 minus x) f(x) dx is 0. Or I can write it here if lambda equal to 2 equation 11 is redundant and gives c 1 equal to 3 c 2, is it ok. And in this case we have solution like y(x) equal to a 1 minus x when lambda equal to let me write it here, ok.

(Refer Slide Time: 23:02)

$$(1-\lambda)c_1 + \frac{\lambda}{2}c_2 = \int_0^1 F(x) dx$$

$$-\frac{c_1\lambda}{2} + (1+\lambda)c_2 = \int_0^1 xF(x) dx$$

$$\begin{pmatrix} 1-\lambda & \frac{\lambda}{2} \\ -\frac{\lambda}{2} & 1+\lambda \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \begin{pmatrix} \int_0^1 F(x) dx \\ \int_0^1 xF(x) dx \end{pmatrix} \quad c_1 = 0 = c_2$$

$$z(x) = F(x) + \lambda (c_1 - 3c_2 x)$$

\therefore If $F(x) = 0$ $-c_1 + 3c_2 = \int_0^1 F(x) dx = 0$

$c_1 = 3c_2$ $-c_1 + 3c_2 = \int_0^1 xF(x) dx = 0$

$$= \int_0^1 F(x) + \lambda 3c_2 (1-x) = A (1-x)$$

So here your solution is what solution is y(x) is equal to f(x) plus lambda times let me look at here solution is what we have written here we have a solution lambda times c 1 minus 3 c 2 x. 3c 2 this is c 2, ok. So here when lambda equal to 2 and f(x) is equal to 0 so in this case lambda equal to 2 equation number 11 is basically what, equation number 11 is minus c 1 plus 3 c 2 is equal to 0 to 1 f(x) dx.

Now here $f(x)$ is 0 so it is basically 0, if you look at the second equation minus c_1 plus $3c_2$ equal to 0 to $\int_0^1 f(x) dx$. So again this is 0 $f(x)$ is 0 so it is equal to 0. So this basically these two equations is the same equation so I can write it c_1 equal to $3c_2$.

So when we take c_1 equal to $3c_2$ a then we have $y(x)$ equal to $f(x)$ plus lambda I am writing c_1 as $3c_2$ so i can take $3c_2$ common and I can write it here $1 - x$. So if I represent $f(x)$ is already 0 so this is 0. So i can write it this as a times $1 - x$ where a is some constant here constant is $3\lambda c_2$.

(Refer Slide Time: 24:40)

Similarly (12) is compatible only when

$$\frac{1}{3} \int_0^1 F(x) dx = \int_0^1 xF(x) dx \quad \text{or} \quad \int_0^1 (1-3x)F(x) dx = 0. \quad (14)$$

in each of the above cases the corresponding equations (11) and (12) are redundant.

First let us consider the case when

$$F(x) = 0. \quad (15)$$

so that (5) is homogeneous. Then if $\lambda \neq \pm 2$, the only solution is the trivial solution.

- If $\lambda = 2$, equation (11) is redundant and gives $c_1 = 3c_2$. Thus in this case (6) gives the solution

$$y(x) = A(1-x) \quad \text{when} \quad \lambda = 2 \quad (16)$$

$A = 6c_2$ is an arbitrary constant. The function $(1-x)$ and all its non-zero multiples are the eigen function corresponding to the eigen value $\lambda = +2$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

So I can write our solution here that if lambda equal to 2 and $f(x)$ equal to 0 then in this case our solution $y(x)$ is written as a into $(1 - x)$ where a is some arbitrary constant here it is given as λc_2 oh sorry $6c_2$. The function $1 - x$ is called Eigen function corresponding to lambda equal to 2.

So here lambda equal to 2 is one of the Eigen value and the corresponding Eigen function is given as $(1 - x)$ and any non zero multiple of $1 - x$

Similarly look at the (quotient) look at the solution for lambda equal to minus 2 and $f(x)$ equal to 0. So when lambda equal to minus 2 in that case.

(Refer Slide Time: 25:25)

• Similarly we find the solution

$$y(x) = B(1 - 3x) \text{ when } \lambda = -2 \quad (17)$$

$B = -2c_1 = -2c_2$ is an arbitrary constant, so that $(1 - 3x)$ is the eigen function corresponding to the eigen value $\lambda = -2$.

Equation (6) shows that any solution of (5) is expressible in the form

$$y(x) = F(x) + C_1(1 - x) + C_2(1 - 3x), \quad (18)$$

where $C_1 = 3\lambda(c_1 - c_2)/2$ and $C_2 = \lambda(3c_2 - c_1)/2$.

NPTEL ONLINE CERTIFICATION COURSE 11

If you look at the equation number 12 here then we will get c_1 equal to c_2 because $f(x)$ is 0 so c_1 is equal to c_2 in this case the solution is given here. So corresponding to λ equal to minus 2 and $f(x)$ is equal to 0 we have c_1 equal to c_2 and your solution is reduced to $y(x)$ is equal to $f(x)$ is simply 0 here $f(x)$ is simply 0 here and c_1 is equal to c_2 .

So c_1 I can take it out so it is λ equal to minus 2. So minus 2 c_1 is out c_1 and this is $1 - 3(x)$. So I can write it here $y(x)$ equal to some $b(1 - 3(x))$ where b is simply minus 2 c_1 or minus 2 c_2 because here we have c_1 equal to c_2 . So in this case where λ is equal to minus 2 and $f(x)$ is simply 0 then $y(x)$ is given as $b(1 - 3x)$.

(Refer Slide Time: 26:24)

$$(1-\lambda)c_1 + \frac{\lambda}{2}c_2 = \int_0^1 F(x)dx$$

$$-\frac{c_1\lambda}{2} + (1+\lambda)c_2 = \int_0^1 x F(x)dx$$

$$\begin{pmatrix} 1-\lambda & \frac{\lambda}{2} \\ -\frac{\lambda}{2} & 1+\lambda \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \begin{pmatrix} \int_0^1 F(x)dx \\ \int_0^1 x F(x)dx \end{pmatrix}$$

$c_1 = 0 = c_2$

$\lambda = -2, F(x) = 0, c_1 = c_2$

$y(x) = -2c_1(1-3x)$

$y(x) = B(1-3x)$

$B = -2c_1 = -2c_2$

$y(x) = F(x) + \lambda(c_1 - 3c_2x)$

$y(x) = F(x) + \alpha(1-x) + \beta(1-3x)$

So I can say that lambda equal to minus 2 is an Eigen value and the corresponding Eigen function is given by 1 minus 3x and a non zero multiple of 1 minus 3(x). Now if you look at with this information I can say that our solution y(x) which is given here as f(x) plus lambda times c 1 minus 3(c 2) x. I can simply rewrite in terms of Eigen function that is (1 minus x) and (1 minus 3x).

So I can simply write this as write it here I can write it here as y(x) plus f of sorry equal to f(x) plus lambda times. Now I am going to write it here I am going to write alpha times say 1 minus x lambda time (1 minus x) plus you do not need this alpha here, alpha times (1 minus x) and beta times 1 minus 3(x) and you can easily find out the value alpha and beta from comparing the comparison of these two things.

(Refer Slide Time: 27:41)

• Similarly we find the solution

$$y(x) = B(1 - 3x) \text{ when } \lambda = -2 \quad (17)$$

$B = -2c_1 = -2c_2$ is an arbitrary constant, so that $(1 - 3x)$ is the eigen function corresponding to the eigen value $\lambda = -2$.

Equation (6) shows that any solution of (5) is expressible in the form

$$y(x) = F(x) + C_1(1 - x) + C_2(1 - 3x), \quad (18)$$

where $C_1 = 3\lambda(c_1 - c_2)/2$ and $C_2 = \lambda(3c_2 - c_1)/2$.

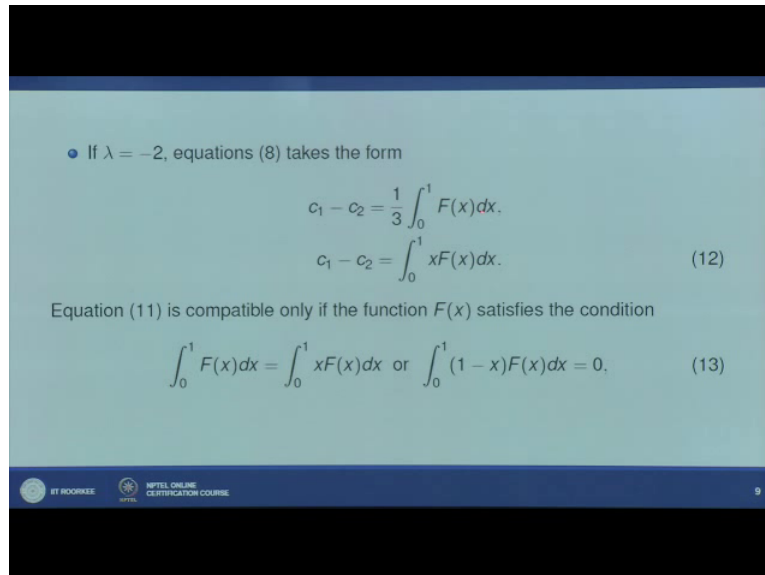

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 11

So here if you look at we can rewrite this solution y(x) as this, equation number 18 which says that y(x) can be written as f(x) plus c 1 times 1 minus x capital C times minus x plus capital C 2 times 1 minus 3x where you can find out capital C 1 and C 2 just like comparing the previous form of the solution and this form of the solution here capital C 1 is given as my 3 lambda C 1 minus C 2 by 2 and capital C 2 is given as lambda times 3 C 2 minus C 1 divided by 2.

So it means that your solution can be written as function f(x) which is non homogeneous terms plus linear combinations of Eigen function corresponding to Eigen values here. So solution is given by this.

Now we can say that any solution of (5) can be expressed as the sum of $f(x)$ and some linear combination of the Eigen function. Now look at the non homogeneous case it means when $f(x)$ is not equal to 0 then we know that if λ is not equal to plus minus 2 then unique solution exists. But what happens when λ plus 2 or minus 2.

(Refer Slide Time: 29:00)

• If $\lambda = -2$, equations (8) takes the form

$$c_1 - c_2 = \frac{1}{3} \int_0^1 F(x) dx.$$

$$c_1 - c_2 = \int_0^1 xF(x) dx. \quad (12)$$

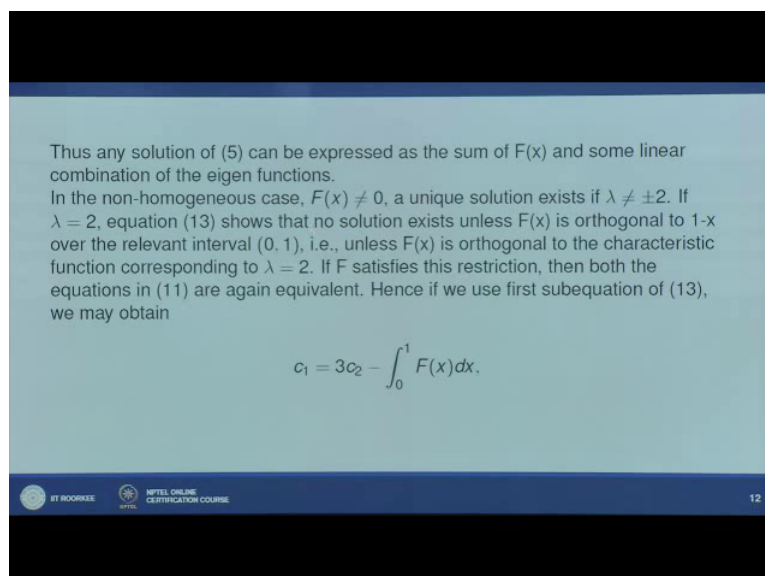

Equation (11) is compatible only if the function $F(x)$ satisfies the condition

$$\int_0^1 F(x) dx = \int_0^1 xF(x) dx \text{ or } \int_0^1 (1-x)F(x) dx = 0. \quad (13)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

So if I look at λ equal to 2 then in that case look at here this thing this is corresponding to λ equal to 2. So λ equal to 2 and $f(x)$ is non zero then this equation $\int_0^1 f(x) dx$ equal to $\int_0^1 x f(x) dx$ which we have obtained from here. So this will make sense only when $\int_0^1 (1-x) f(x) dx$ is 0. So it means that this function $f(x)$ is orthogonal to $1-x$ in the interval 0 to 1.

(Refer Slide Time: 29:40)

Thus any solution of (5) can be expressed as the sum of $F(x)$ and some linear combination of the eigen functions.

In the non-homogeneous case, $F(x) \neq 0$, a unique solution exists if $\lambda \neq \pm 2$. If $\lambda = 2$, equation (13) shows that no solution exists unless $F(x)$ is orthogonal to $1-x$ over the relevant interval $(0, 1)$, i.e., unless $F(x)$ is orthogonal to the characteristic function corresponding to $\lambda = 2$. If F satisfies this restriction, then both the equations in (11) are again equivalent. Hence if we use first subequation of (13), we may obtain

$$c_1 = 3c_2 - \int_0^1 F(x) dx.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So I can write it here like this that if lambda equal to 2 this equation, equation for finding small c_1 and c_2 will give you solution when $f(x)$ is orthogonal to $(1 - x)$ over the interval $(0, 1)$. Or I can say that $f(x)$ is orthogonal to characteristic function what is $1 - x$ it is the characteristic function or Eigen function corresponding to lambda equal to 2. So we can say that for lambda equal to 2 we can find out c_1 and c_2 only when that $f(x)$ is orthogonal to the Eigen function corresponding to lambda equal to 2.

Or I can write it that if satisfy this instruction then in that case you can use any one of the formula of eleven. So here if you look at in eleven if we have $\int_0^1 f(x) dx$ is same as $\int_0^1 (1 - x) f(x) dx$, so I can use any of these two integral I can write it $c_1 = 3c_2 - \int_0^1 f(x) dx$, or I can write it this thing, ok.

In that case your let me here then I can write it the value of c_1 as in terms of c_2 as $c_1 = 3c_2 - \int_0^1 f(x) dx$. I am using the first sub equation of eleven. You can use second also no problem, right?

(Refer Slide Time: 31:01)

so that (6) gives the solution as follows:

$$\lambda = 2: y(x) = F(x) - 2 \int_0^1 F(x) dx + A(1 - x).$$

when

$$\int_0^1 (1 - x)F(x) dx = 0. \quad (19)$$

where $A = 6c_2$ is again an arbitrary constant. Thus in this case, infinitely many solutions exist, differing by a multiple of relevant characteristic function.

NPTEL ONLINE CERTIFICATION COURSE 13

In that case lambda equal to 2 $y(x)$ is given as $f(x)$ minus 2 times $\int_0^1 f(x) dx$ plus $A(1 - x)$. Now here $f(x)$ is a function which satisfy this property $\int_0^1 (1 - x) f(x) dx = 0$.

So it means that this solution exist only when $f(x)$ you have a function $f(x)$ which is orthogonal to Eigen function corresponding to lambda equal to 2 is that ok. And here we already know that here we have infinite many solution because A is completely arbitrary here, A is $6c_2$ and c_2 is completely arbitrary. So here we can have infinite many solution.

(Refer Slide Time: 31:48)

Similarly, if $\lambda = -2$ there is no solution unless $F(x)$ is orthogonal to $(1 - 3x)$ over $(0, 1)$ in which case infinitely many solutions exist as follows:

$$\lambda = -2: \quad y(x) = F(x) - \frac{2}{3} \int_0^1 F(x) dx + B(1 - 3x).$$

where

$$\int_0^1 (1 - 3x)F(x) dx = 0. \quad (20)$$

Here $B = -2c_2$ is an arbitrary constant.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

Now the same similar case we can consider for lambda equal to minus 2 so when lambda equal to minus 2 if you go back to your equation number this or we look at here. So if lambda equal to minus 2 so this will make sense if these two are equal, these two are equal means you are 0 to 1 1 minus 3x f(x) dx is equal to 0.

So it means that f(x) is orthogonal to 1 minus 3x, now what is this 1 minus 3x if you look at we have already calculated that 1 minus 3x is an Eigen function corresponding lambda equal to minus 2 it means that if we use this information I can say that for lambda equal to minus 2 there is no solution unless f(x) is orthogonal to this. And what is this function it is an Eigen function corresponding to lambda equal to , lambda equal to minus 2.

So I can say that in case lambda equal to minus 2 y(x) is given as f(x) minus 2 times 2 by 3 0 to 1 f(x) dx plus b times 1 minus 3x. Again here f(x) is satisfying this condition orthogonal condition and b is minus 2c 2 or minus 2 c 1 whatever and c 2 is an arbitrary thing so this is going to be infinitely many solutions here.

So it means that when we have a coefficient matrix which is a singular matrix then we had to look at the Eigen values and Eigen function and if function capital F(x) satisfy certain orthogonality condition then only we can have it non trivial solution. And in this particular case we have infinite many solutions here .

If you look at some example of capital F(x) for which this condition holds an we have a solution like this. So if you look at I can take f(x) as say 1 minus x or you can say like this

that here if I take $f(x)$ equal to $1 - x$ which is an Eigen function corresponding to λ equal to 2 . Then (20) will hold and we have a non trivial solution here, is that ok.

So in today's lecture we have seen that how to find out a solution of Fredholm integral equation of second kind when the kernel is separable kernel, Thank you for listening and we will meet again for next lecture, Thank you!
