**Power Method**

Hello everyone, uhh so welcome to the 4<sup>th</sup> lecture of this module and today we are going to discuss one more method for finding eigenvalues and eigenvectors of a matrix. So in the last lecture we have discussed Jacobi method for finding eigenvalues for a symmetric matrix and there we have uhh we have use the similarity transformation in such a way the a similar matrix has uhh we a similar matrix found corresponding to the given matrix and that similar matrix is just like uhh just a diagonal matrix where the eigenvalues are the diagonal elements, like Jacobi method was restrict up to symmetric matrix only, today we are going to discuss a method which is applicable to any square matrix; however again we are having some conditions to apply power method, which is we are going to discuss today and we will discuss about those conditions.

(Refer Slide Time: 1:40)

Power method for finding dominant eigenvalues

Let  $A$  be an  $n \times n$  matrix. The eigenvalues are calculated on solving the characteristic equation of  $A$  given by

$$\lambda^n + c_{n-1}\lambda^{n-1} + c_{n-2}\lambda^{n-2} + \dots + c_0 = 0$$

**Dominant eigenvalue and dominant eigenvector**

Let  $\lambda_1, \lambda_2, \dots, \lambda_n$  be the eigenvalues of an  $n \times n$  matrix  $A$ .  $\lambda_1$  is said to be the dominant eigenvalue of  $A$  if

$$|\lambda_1| > |\lambda_i|, \quad i = 2, 3, \dots, n.$$

Eigenvector corresponding to  $\lambda_1$  are called dominant eigenvector of  $A$ .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

So first of all, let  $A$  be a square matrix of order  $n$ . the eigenvalues are calculated just by solving the characteristic equation, which is given as  $\lambda^n + c_{n-1}\lambda^{n-1} + c_{n-2}\lambda^{n-2} + \dots + c_0 = 0$ . So it is a  $n$  degree polynomial in  $\lambda$  and roots zeros of this polynomial will give you the eigenvalues. Let us say eigenvalues are  $\lambda_1, \lambda_2, \dots, \lambda_n$ , where some of them may be equal or

repeated we will say that  $\lambda_1$  is a dominant eigenvalue of  $A$ , if this condition is satisfied means, the absolute value of  $\lambda_1$  is greater than rest of the absolute values of rest of the eigenvalues that is  $|\lambda_1| > |\lambda_i|$  for  $i = 2, 3, \dots, n$  and if this condition holds  $\lambda_1$  is the dominant eigenvalue and the corresponding eigenvector is called dominant eigenvector of  $A$ .

(Refer Slide Time: 2:47)

**Power method for finding dominant eigenvalues**

**Example**  
Consider the matrix

$$A = \begin{pmatrix} 2 & -12 \\ 1 & -5 \end{pmatrix}$$

The characteristic polynomial of  $A$  is  $\lambda^2 + 3\lambda + 2 = (\lambda + 1)(\lambda + 2)$ . Thus  $\lambda_1 = -1$  and  $\lambda_2 = -2$  are the eigenvalues. Also  $|-2| > |-1|$ , so  $-2$  is the dominant eigenvalue. Eigenvector of  $A$  corresponding to  $\lambda_2 = -2$  will be given by equation  $Ax = \lambda_2 x$ . On solving this equation, we get  $x = t \begin{pmatrix} 3 \\ 1 \end{pmatrix}, t \neq 0$ .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So for example, if I take this 2 by 2 matrix so the characteristic polynomial of this matrix is  $\lambda^2 + 3\lambda + 2$ , which is having zeros as  $\lambda_1 = -1$  and  $\lambda_2 = -2$ . So the eigenvalues are -1 and -2 for this matrix. Now if we see that absolute value of -2 is greater than absolute value of -1. Hence, -2 is the dominant eigenvalue of this matrix and corresponding eigenvector is (3, 1).

(Refer Slide Time: 3:29)

Power method for finding dominant eigenvalues

**Preconditions**

The power method can be used when

- 1 Eigenvalues can be arranged in the following way
$$|\lambda_1| > |\lambda_2| \geq |\lambda_3| \geq \dots \geq |\lambda_n|$$
so that  $|\lambda_1|$  is the dominant eigenvalue.
- 2  $A_{n \times n}$  has  $n$  linearly independent eigenvectors.

IT ROORKEE NITEL ONLINE CERTIFICATION COURSE 5

Now what are the conditions to apply power method? First of all, eigenvalues can be arranged in the following way that is, the dominant eigenvalue should be there for the matrix and there should not be any repetition of dominant eigenvalue, for example, if we are having a 3 by 3 matrix, there should be 1 dominant eigenvalue which is not equals to others, for example if A is 3 by 3 and we are having eigenvalues minus 5, 3 and 2. Then here minus 5 is clearly dominant eigenvalue, but if we are having eigenvalues like -5, 5 and 4. Here, we cannot apply power method as such and we will not be able to find out the eigenvalue, because here the dominant eigenvalue is -5 as well as 5 and it is repeated. So here  $\lambda_1$  is not clear strictly greater than the rest of the eigenvalue in terms of absolute value. The second condition is which is again very important that the matrix A should have a linearly independent eigenvectors. It means A should be similar to A diagonal matrix if we talk in terms of similarity transformation.

(Refer Slide Time: 4:51)

**Power method for finding dominant eigenvalues**

Let the matrix  $A$  contains  $n$  linearly independent eigenvectors  $\{v_1, v_2, \dots, v_n\}$ . Where,  $v_1$  is the eigenvector corresponding to the dominant eigenvalue  $\lambda_1$ . If  $v$  is any vector, it can be written as

$$v = c_1 v_1 + c_2 v_2 + \dots + c_n v_n \quad (1)$$

where,  $c_1, c_2, \dots, c_n$  are scalars.  
Premultiplying equation (1) by  $A$  and using  $Av_1 = \lambda_1 v_1$ ,  $Av_2 = \lambda_2 v_2, \dots$ , we get

$$\begin{aligned} Av &= c_1 \lambda_1 v_1 + c_2 \lambda_2 v_2 + \dots + c_n \lambda_n v_n \\ &= \lambda_1 \left[ c_1 v_1 + c_2 \left( \frac{\lambda_2}{\lambda_1} \right) v_2 + \dots + c_n \left( \frac{\lambda_n}{\lambda_1} \right) v_n \right] \end{aligned}$$

BIT ROORKEE  NITEL ONLINE CERTIFICATION COURSE 6

So with these two conditions let us derive the power method.

(Refer Slide Time: 4:57)

$A_{n \times n}$ ,  $|\lambda_1| > |\lambda_2| \geq |\lambda_3| \dots \geq |\lambda_n|$   
 $v_1 \quad v_2 \quad \dots \quad v_n$   
 If  $v \in \mathbb{R}^n$   
 $v = c_1 v_1 + c_2 v_2 + \dots + c_n v_n$   
 $Av = c_1 Av_1 + c_2 Av_2 + \dots + c_n Av_n$   
 $= c_1 \lambda_1 v_1 + c_2 \lambda_2 v_2 + \dots + c_n \lambda_n v_n$   
 $Av = \lambda_1 \left[ c_1 v_1 + c_2 \left( \frac{\lambda_2}{\lambda_1} \right) v_2 + \dots + c_n \left( \frac{\lambda_n}{\lambda_1} \right) v_n \right]$   
 $A^2 v = \lambda_1^2 \left[ c_1 v_1 + c_2 \left( \frac{\lambda_2}{\lambda_1} \right)^2 v_2 + \dots + c_n \left( \frac{\lambda_n}{\lambda_1} \right)^2 v_n \right]$   
 $\vdots$   
 $A^k v = \lambda_1^k \left[ c_1 v_1 + c_2 \left( \frac{\lambda_2}{\lambda_1} \right)^k v_2 + \dots + c_n \left( \frac{\lambda_n}{\lambda_1} \right)^k v_n \right]$

So let  $A$  is  $n$  by  $n$  matrix and it is having eigenvalues  $\lambda_1$  which is strictly greater than in terms of absolute value to rest of the eigenvalues, moreover we are having eigenvector as  $v_1$  corresponding to  $\lambda_1$ ,  $v_2$  corresponding to  $\lambda_2$  and  $v_n$  corresponding to  $\lambda_n$  and here, we are assuming that  $v_1, v_2, v_n$  are linearly independent. So if these vectors are linearly independent, then any vector  $v$  from the vector space  $\mathbb{R}^n$  can be written as the linear combination of these eigenvectors. So if  $v$  belongs to  $\mathbb{R}^n$  or if matrix is from the complex number and from the  $C_n$  so if we form  $\mathbb{R}^n$  then we can write  $v$  equals to  $C_1 v_1$  plus  $C_2 v_2$  plus  $C_n v_n$ . Here,  $C_1, C_2, C_n$  are scalars.

Now if I multiply by matrix A, in this equation I will get in the left hand side A into V and then  $C_1 A$  into  $V_1$  plus  $C_2 A$  into  $V_2$  plus  $C_n A$  into  $V_n$ , as we know that  $V_1$  is an eigenvector corresponding eigenvalue  $\lambda_1$  for the matrix A. So I can write  $C_1 \lambda_1 V_1$ . Similarly, this term I can write  $\lambda_2 V_2$  plus  $C_n \lambda_n V_n$  or if I take  $\lambda_1$  common from the right hand side, I can write  $C_1 V_1$  plus  $C_2 \lambda_2$  upon  $\lambda_1$  into  $V_2$ . So this is equals to  $AV$ .

If I multiply one more time by the matrix A, in this equation I will get  $A^2$  into V in the left hand side and this will become, so  $C_1 V_1$  plus  $C_2$  and the square of  $\lambda_2$  upon  $\lambda_1$  into  $V_2$  plus  $C_n$  square of this ratio term into  $V_n$  or if I continue by multiplying A again A again, let us say I multiply k time it will become  $A^k$  into V equals to  $\lambda_1^k$  into  $C_1 V_1$  plus  $C_2 \lambda_2^k$  upon  $\lambda_1^k$  into  $V_2$  and finally the last term will become

Now look at this equation, here we are having in the this term  $\lambda_2^k$  upon  $\lambda_1^k$ . Similarly, in the next term we will be having  $\lambda_3^k$  upon  $\lambda_1^k$  and so on. Here our assumption is that  $\lambda_1$  is the dominant eigenvalue. It means that this particular term  $\lambda_2^k$  upon  $\lambda_1^k$  will be less than 1. Similarly  $\lambda_3^k$  upon  $\lambda_1^k$  will be less than 1 and up to  $\lambda_n^k$  upon  $\lambda_1^k$  which is again place then 1.

(Refer Slide Time: 9:50)

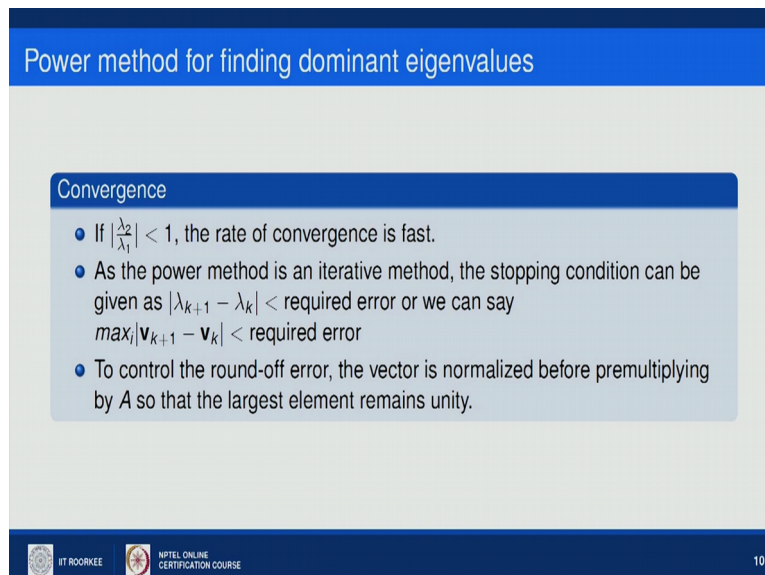

$$\begin{aligned}
 & k \rightarrow \infty \\
 & A^k V = \lambda_1^k C_1 V_1 \\
 & \lambda_1 = \lim_{k \rightarrow \infty} \frac{(A^{k+1} V)_r}{(A^k V)_r} \\
 \\ 
 & A V = \lambda_1 \left[ C_1 V_1 + C_2 \left( \frac{\lambda_2}{\lambda_1} \right) V_2 + \dots + C_n \left( \frac{\lambda_n}{\lambda_1} \right) V_n \right] \\
 & A^2 V = \lambda_1^2 \left[ C_1 V_1 + C_2 \left( \frac{\lambda_2}{\lambda_1} \right)^2 V_2 + \dots + C_n \left( \frac{\lambda_n}{\lambda_1} \right)^2 V_n \right] \\
 & \vdots \\
 & A^k V = \lambda_1^k \left[ C_1 V_1 + C_2 \left( \frac{\lambda_2}{\lambda_1} \right)^k V_2 + \dots + C_n \left( \frac{\lambda_n}{\lambda_1} \right)^k V_n \right]
 \end{aligned}$$

So when k is tending to infinity my  $A^k V$  will become  $\lambda_1^k$  into  $C_1 V_1$  it means I can find out  $\lambda_1$  as limit k tending to infinity by this ratio and here R is the component of the vector this particular vectors having the highest value in magnitude. So this

will give me dominant eigenvalue and since, we are using various powers of A that is why we are saying it the power method and from this equation, it is clear that if  $\lambda_1$  is the eigenvalue that is the dominant eigenvalue then the corresponding eigenvector will be  $V_1$ . So with this I can talk about the conversions of this power method.

So if  $\lambda_2$  upon  $\lambda_1$  and absolute of this ratio term is less than 1, the rate of conversion is fast, moreover whatever will be the means if it is quite small then 1 the method we converse faster if it is close to 1, this ratio term, the method will converge slowly, as we know that power method is an iterative method, because each time we are making we are starting with the initial solution  $V_0$ , then we are finding  $V_1$  as A of  $V_1$ , then  $V_2$  will be A of  $V_2$ ,  $V_3$  will be A of  $V_2$  and so on until unless it will not converge.

(Refer Slide Time: 12:06)

Power method for finding dominant eigenvalues

**Convergence**

- If  $|\frac{\lambda_2}{\lambda_1}| < 1$ , the rate of convergence is fast.
- As the power method is an iterative method, the stopping condition can be given as  $|\lambda_{k+1} - \lambda_k| < \text{required error}$  or we can say  $\max_i |v_{k+1} - v_k| < \text{required error}$
- To control the round-off error, the vector is normalized before premultiplying by A so that the largest element remains unity.

VT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

So there should be some stopping criteria and the stopping condition is if in the two successive iterations  $\lambda$  is less than a given threshold, okay, in terms of 10<sup>-3</sup> or 10<sup>-5</sup> whatever accuracy you want in your method or the maximum component in 2 successive vector  $V_{k+1}$  and  $V_k$  and difference of this, which is having the maximum value is less than a given threshold. Moreover to control the round off error the vector is normalize before pre-multiplying by A so that the largest element remains unity, for example, if you start with 1,1,1,1 and after multiplying with A you are getting let us say some vector 2, 3,4. So what I will do I will normalize it, in such a way that the biggest component of this  $V_2$  vector that is 4 should become 1 so that vector will become 2 by 4, 3 by 4 and 1.

(Refer Slide Time: 13:30)

### Power method for finding dominant eigenvalues

#### Convergence

Let  $\mathbf{v}_0$  be the arbitrary non-zero initial vector which is not orthogonal to vector  $\mathbf{v}_1$ .

$$\mathbf{y}_{k+1} = \mathbf{A}\mathbf{v}_k \quad (5)$$
$$\mathbf{v}_{k+1} = \mathbf{y}_{k+1}/\mathbf{m}_{k+1} \quad (6)$$

where  $\mathbf{m}_{k+1}$  is the largest element in  $\mathbf{y}_{k+1}$  magnitude. In this case,

$$\lambda_1 = \lim_{k \rightarrow \infty} \frac{(\mathbf{y}_{k+1})_r}{(\mathbf{v}_k)_r}, \quad r = 1, 2, \dots, n \quad (7)$$

Finally,  $\mathbf{v}_{k+1}$  is the required eigenvector.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

If we talk about eigenvector, so we start with  $\mathbf{V}_0$  as the initial vector and the condition is that this  $\mathbf{V}_0$  should not be orthogonal to vector  $\mathbf{V}_1$ . So and it should be a non-zero vector obviously, because we are finally converge in this particular vector is converging to the eigenvector. So  $\mathbf{y}_{k+1}$  equals to  $\mathbf{A}$  of  $\mathbf{V}_k$  then I will find out  $\mathbf{V}_{k+1}$  as  $\mathbf{y}_{k+1}$  upon  $\mathbf{m}_{k+1}$  and as I told you where  $\mathbf{m}_{k+1}$  is the largest element in  $\mathbf{y}_{k+1}$  in magnitude. So in this case,  $\lambda_1$  will be limit  $k$  tending to infinity,  $\mathbf{y}_{k+1}$   $r$  upon  $\mathbf{V}_k$   $r$ . finally,  $\mathbf{V}_{k+1}$  will be the required eigenvector corresponding to  $\lambda_1$ .

(Refer Slide Time: 14:00)

### Power method for finding dominant eigenvalues

#### Example

Consider the matrix

$$\mathbf{A} = \begin{bmatrix} 3 & -1 & 0 \\ -2 & 4 & -3 \\ 0 & -1 & 1 \end{bmatrix}$$

Let the initial column vector be

$$\mathbf{v}_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

Let us take an example of this method, just consider this 3 by 3 matrix and let the initial column vector be 1, 1, 1.

(Refer Slide Time: 14:04)

Power method for finding dominant eigenvalues

Example

First iteration is given as

$$\mathbf{v}_1 = \mathbf{A}\mathbf{v}_0 = \begin{bmatrix} 3 & -1 & 0 \\ -2 & 4 & -3 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 2 \\ -1 \\ 0 \end{bmatrix}$$

So,

$$\mathbf{y}_1 = 2 \begin{bmatrix} 1 \\ -0.5 \\ 0 \end{bmatrix}$$

with  $\lambda_1 = 2$ , the largest magnitude component of  $\mathbf{v}_1$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So first of all I will find out  $\mathbf{V}_1$ , uhh  $\mathbf{V}_1$  will be  $\mathbf{A}$  into  $\mathbf{V}_0$ ,  $\mathbf{A}$  is this 3 by 3 matrix,  $\mathbf{V}_0$  is 1, 1, 1 this column vector after multiplying I am getting another column vector, which is  $\mathbf{V}_1$ , 2, -1 and 0. Now what I will do first of all, I will find out from  $\mathbf{V}_1$  to  $\mathbf{y}_1$  and  $\mathbf{y}_1$  will be, I will see which is the biggest component in this vector in terms of a float value and here it is 1. So I will divide this  $\mathbf{V}_1$  by 2. So  $\mathbf{y}_1$  will become 1 by 2, 1, 0.5, 0. So here I can say that, in this iteration my eigenvalue is 2 and the eigenvector is 1, -0.5, 0.

(Refer Slide Time: 14:55)

Power method for finding dominant eigenvalues

Example

Second iteration:

$$\mathbf{v}_2 = \begin{bmatrix} 3 & -1 & 0 \\ -2 & 4 & -3 \\ 0 & -1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ -0.5 \\ 0 \end{bmatrix} = \begin{bmatrix} 3.5 \\ -4 \\ 0.5 \end{bmatrix}$$
$$\mathbf{y}_2 = -4 \begin{bmatrix} -0.875 \\ 1 \\ -0.125 \end{bmatrix}$$

with  $\lambda_2 = -4$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

## Power method for finding dominant eigenvalues

### Example

After 3 iterations, there is a very little sign of convergence of  $\lambda_r$ . However, after 14 iterations  $|\lambda_{14} - \lambda_{13}| < 0.0001$ . Hence, the power method converges to  $\lambda_{14} = 5.4773$  which is the dominant eigenvalue of **A**. The corresponding eigenvector is

$$\begin{bmatrix} -0.4037 \\ 1 \\ -0.2233 \end{bmatrix}$$

IT ROORKEE

NPTEL ONLINE  
CERTIFICATION COURSE

16

Then I will calculate  $V_2$ .  $V_2$  will be  $A$  into  $y_1$  and  $A$  into  $y_1$  when I will calculate it will become 3.5 minus 4.5, again I will divide this vector by 4 so that this term will become 1, -0.875, 1 and -0.125. So here in this iteration eigenvalue the approximation of eigenvalue is minus 4. So just look in first iteration it was 2, in the second iteration, it is coming -4 and similarly, we are getting a deviation is eigenvector. In the third iteration, eigenvalue becomes 6.125 that is approximation and  $y_3$  becomes -0.918, 1 and -0.1837.

So we are not getting any sign of convergence so far in 3 iterations however if we go up to 14 iterations what we found that the approximate of eigenvalue which I am getting in 14<sup>th</sup> iteration minus which I am getting in 13<sup>th</sup> iteration that absolute difference between these two is less than  $10^{-4}$  and hence, the power method converge to eigenvalue 5.4773, which is the dominant eigenvalue of the given matrix and the corresponding eigenvector becomes -0.4037, 1 and -0.2233.

(Refer Slide Time: 16:40)

### Power method for finding dominant eigenvalues

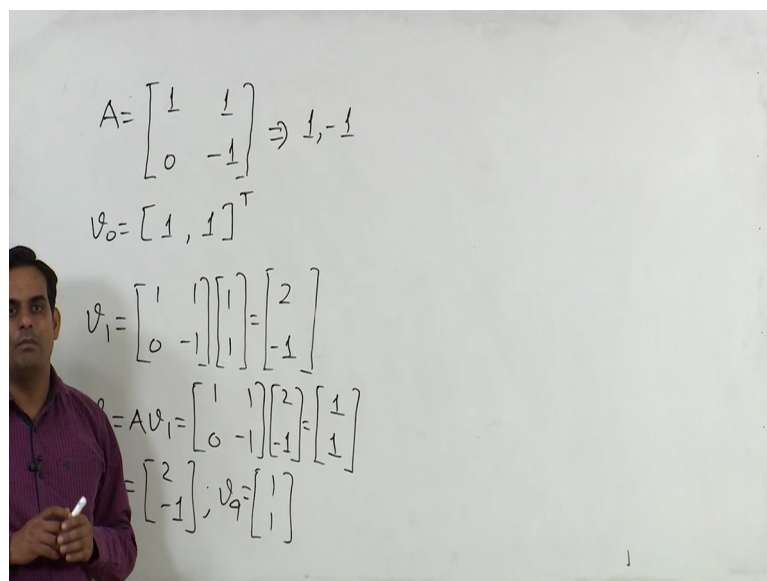

#### Disadvantages of power method

- 1 If the initial column vector  $\mathbf{v}_0$  is an eigenvector of  $\mathbf{A}$  other than that corresponding to the dominant eigenvalue then the method will fail since the iteration will converge to the wrong eigenvalue.
- 2 The speed of convergence of the power method depends on the ratio  $\frac{\text{magnitude of dominant eigenvalue } \lambda_1}{\text{magnitude of next largest eigenvalue}}$   
If this ratio is small, the method will converge slowly.
- 3 The power method only gives one dominant eigenvalue.

IT ROORKEE NITEL ONLINE CERTIFICATION COURSE 17

There are some disadvantages or limitations of this method. The first one is if the initial column vector  $\mathbf{V}_0$  is an eigenvector of  $\mathbf{A}$  other than the dominant eigenvector, then the method will fail since the iteration will converge to wrong eigenvalue, moreover the speed of convergence depends on the ratio magnitude of dominant eigenvalue  $\lambda_1$  upon magnitude of the next largest eigenvalue. If the ratio is small, the method will converge slowly. The power method only gives one dominant eigenvalue at a time; okay I will tell you how can we find out other eigenvalues using this method.

(Refer Slide Time: 17:50)

$$\mathbf{A} = \begin{bmatrix} 1 & 1 \\ 0 & -1 \end{bmatrix} \Rightarrow 1, -1$$
$$\mathbf{v}_0 = [1, 1]^T$$
$$\mathbf{v}_1 = \begin{bmatrix} 1 & 1 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 2 \\ -1 \end{bmatrix}$$
$$\mathbf{v}_2 = \mathbf{A}\mathbf{v}_1 = \begin{bmatrix} 1 & 1 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 2 \\ -1 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$
$$\mathbf{v}_3 = \begin{bmatrix} 2 \\ -1 \end{bmatrix}, \mathbf{v}_4 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

So as I told you, there are some limitations when I told you the assumption for applying this method, I told you that there should be a dominant eigenvalue, if this is not the case what will

happen, whether the method will converge or not. Let us see it with an example. So if I take a 2 by 2 matrix, let us say 1, 1, 0, -1. Let us find out the eigenvalue of this matrix using power method. So let me start with a initial vector  $V_0$  which is 1,1. So  $V_1$  will become 1, 1, 0, -1 that is my matrix  $A$  into  $V_0$  1, 1 so 1 plus 1, 2 and -1.

Now I will calculate 2,  $V_2$  will become  $A$  of  $V_1$ . So it is 1, 1, 0, -1 into 2 minus 1. So 2 minus 1 will become 1 and it became 1, 1, again then if I will calculate  $V_3$ ,  $V_3$  will come 2 minus 1,  $V_4$  will come 1, 1 and so on. So my method will stuck here in these two vectors in either I will get for the odd iterations of  $V$ , I will get 2, -1 for the even iterations like 2, 4, 6 I will get 1,1 and I will it will never converge. Why it is happening. This is clear from here, if you see the eigenvalue of this matrix, it is an upper triangular matrix and here eigenvalues are 1 and -1 and the region of this oscillation is very simple that the matrix is not having the dominant eigenvalue that is why the condition that the matrix should have dominant eigenvalue is quite important for applying the power method up to now we have seen that using the power method, we can calculate up only dominant eigenvalues and corresponding eigenvector, suppose I want to calculate other eigenvalues also.

(Refer Slide Time: 20:33)

**Power method**

**Finding nondominant eigenvalues**

- Once the dominant eigenpair  $(\lambda_1, v_1)$  of matrix  $A$  is computed, we may wish to compute  $\lambda_2$ .
- Here, we know that  $|\lambda_1| > |\lambda_2| \geq |\lambda_3| \geq \dots \geq |\lambda_n|$ .
- If  $A$  is symmetric, then it can be proved that if  $u_1 = v_1/|v_1|$ , then  $A_1 = A - \lambda_1 u_1 u_1^T$  has eigenvalues  $0, \lambda_2, \lambda_3, \dots, \lambda_n$  and the eigenvectors of  $A_1$  will be same as of  $A$ .

This application of the power method on  $A_1$  to find non-dominant eigenvalues is called the **method of deflation**.

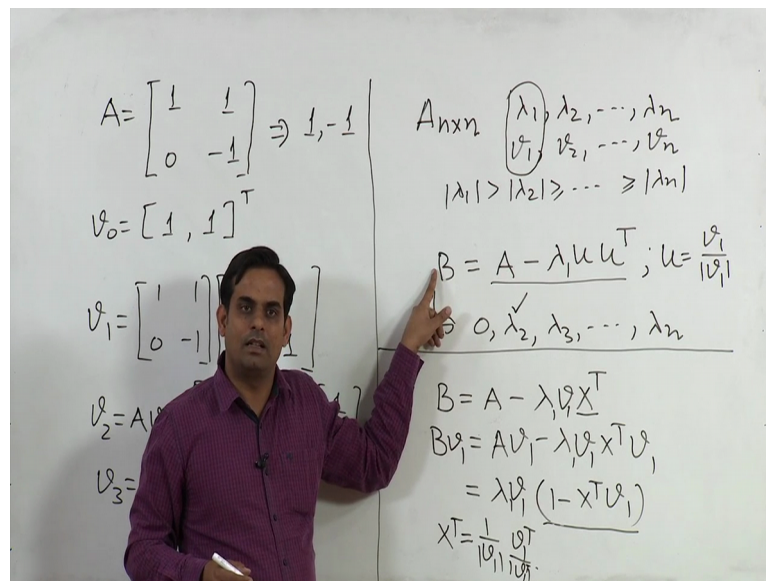

IIT ROORKEE  
 NPTEL ONLINE  
 CERTIFICATION COURSE

19

So we can modify this power method in such a way that we shift the dominant eigenvalue to 0 in a new matrix such that the second 2 dominant eigenvalue become the dominant, for example, if you are having eigenvalues  $\lambda_1, \lambda_2, \lambda_3$ , if  $\lambda_1$  is dominant what we will do we will shift  $\lambda_1$  to zero in some other matrix such that the  $\lambda_2$  becomes the dominant and then in this new matrix we will apply the power method. So this method is called method of deflation and it is based on deflation theorem. So how it works?

So once you calculate the dominant Eigen pair that is  $\lambda_1$   $V_1$  of a matrix as  $A$  you will calculate the or you want to calculate  $\lambda_2$ . Here, so I will take an example of symmetric matrix, but it can be generalized for any other matrix also. So if  $A$  is a symmetric matrix then it can be prove that if  $U_1$  is  $V_1$  upon mod of  $V_1$  then  $A_1$  is  $A$  minus  $\lambda_1 U_1 U_1^T$  has eigenvalues 0,  $\lambda_2$ ,  $\lambda_3$ ,  $\lambda_n$  and the eigenvector of  $A_1$  will be the same as of  $A$ . so this is one of the result of deflation theorem.

(Refer Slide Time: 22:08)

The whiteboard contains the following mathematical content:

$$A = \begin{bmatrix} 1 & 1 \\ 0 & -1 \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix}$$

$$V_0 = \begin{bmatrix} 1 & 1 \end{bmatrix}^T$$

$$V_1 = \begin{bmatrix} 1 & 1 \\ 0 & -1 \end{bmatrix}$$

$$V_2 = A V_1 - \lambda_1 V_1$$

$$V_3 = A V_2 - \lambda_2 V_2$$

$$A_{n \times n} \begin{pmatrix} \lambda_1 & \lambda_2 & \dots & \lambda_n \\ V_1 & V_2 & \dots & V_n \end{pmatrix}$$

$$|\lambda_1| > |\lambda_2| > \dots > |\lambda_n|$$

$$B = \frac{A - \lambda_1 U U^T}{\|U\|^2}; U = \frac{V_1}{\|V_1\|}$$

$$\Rightarrow 0, \lambda_2, \lambda_3, \dots, \lambda_n$$

$$B = A - \lambda_1 V_1 V_1^T$$

$$B V_1 = A V_1 - \lambda_1 V_1 V_1^T V_1$$

$$= \lambda_1 V_1 (1 - V_1^T V_1)$$

$$V_1^T = \frac{1}{\|V_1\|} \frac{V_1^T}{\|V_1\|}$$

So here we are saying that if  $A$  is  $n$  cross  $n$  matrix having eigenvalue  $\lambda_1$   $\lambda_2$ ,  $\lambda_n$  and corresponding eigenvectors are  $V_1$ ,  $V_2$ ,  $V_n$ . Now and also we are assuming that  $\lambda_1$  is the dominant eigenvalue and the corresponding eigenvector to this  $V_1$  that is a dominant eigenvector is  $V_1$ . Now I am saying, if  $A$  is a symmetric matrix, I can calculate a new matrix  $A_1$  or let us say it  $B$ , which is  $A$  minus  $\lambda_1$  into  $U$  into  $U$  transpose, where  $U$  is the unit vector in the direction of  $V_1$  then, this matrix  $B$  will be having the eigenvalues 0,  $\lambda_2$ ,  $\lambda_3$  up to  $\lambda_n$  and the eigenvectors will remain same like  $V_2$ ,  $V_3$ ,  $V_n$  for this new matrix  $B$ . so what we can do, suppose using the power method on this matrix  $A$ , we calculate the dominant eigenvalue and corresponding eigenvector that is  $\lambda_1$  and  $V_1$  and here, this is my  $\lambda_1$  is the dominant eigenvalue in this result.

So I calculate these two what I will do I will apply this transformation, I will get a new matrix  $B$  and again I will apply the power method on  $B$  so that I can calculate the next eigenvalue to the dominant that is  $\lambda_2$  and corresponding eigenvector that is the dominant eigenvalue of  $B$  will be the next two dominant eigenvalue of  $A$  and how we are getting this result? Suppose  $A$  is a symmetric matrix, so I want a new matrix  $B$ , which is something  $A$  minus

$\lambda V$  into  $X^T$ . So I am taking a vector  $X$ , if I multiply this vector  $X$  in this second term of the right hand side of this equation, I get a new matrix  $B$ , which is having the one of the eigenvalue as 0 if  $\lambda$  is the eigenvalue of  $A$ .

Now how? If  $V_1$  is the eigenvector corresponding  $\lambda$  of  $A$ , so I will be having  $B$  of  $V_1$  equals to  $A$  of  $V_1$  minus  $\lambda V_1 X^T V_1$  and as I told you  $\lambda_1$  and  $V_1$  are the dominant pair of matrix  $A$ . So  $AV_1$  can be written as  $\lambda_1 V_1$  and then it will become  $\lambda_1 V_1$  minus  $\lambda_1 V_1 X^T V_1$ . So it will become  $1$  minus  $X^T V_1$ . Now how to choose this vector  $X$  such that one of the eigenvalue of  $B$  should be 0 and the corresponding eigenvectors would be  $V_1$  so here if this term become 0, then what I can have? If this term is 0 and I choose  $X$  in such a way then  $BV_1$  will become  $\lambda_1 V_1$  into 0 that is  $BV_1$  equals to 0 means one of eigenvalue corresponding for which this is the eigenvector should be 0. So for a symmetric matrix I can take this  $X$  as this one so that my this becomes  $U$  and  $\lambda_1 U U^T U U^T$  this becomes the deflation transformation.

Method of Deflation

Example

Consider a symmetric matrix

$$A = \begin{pmatrix} 5 & -2 \\ -2 & 8 \end{pmatrix}$$

Find all the eigenvalues of this matrix using power method together with method of deflation.

Start with  $X_0 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ ;  $X_1 = AX_0 = \begin{pmatrix} 3 \\ 6 \end{pmatrix} \mapsto Y_1 = 1/6 \begin{pmatrix} 1/2 \\ 1 \end{pmatrix}$   $X_2 =$

$AY_1 = \begin{pmatrix} 1/2 \\ 7 \end{pmatrix} \mapsto Y_2 = 1/7 \begin{pmatrix} 1/14 \\ 1 \end{pmatrix}$ ;  $X_3 = AY_2 = \begin{pmatrix} -1.6429 \\ 7.8572 \end{pmatrix}$

20

Let us check this with one of the example again I am taking a 2 by 2 matrix and now I question is find all the eigenvalues of this matrix using power method together with method of deflation. So it is a 2 by 2 matrix, so there will be only 2 eigenvalues, uhh one of the eigenvalue that is the dominant eigenvalue we can calculate using the power method and the other one, we will use the method of deflation in power method.

(Refer Slide Time: 28:08)

Continuing this we get

$n$	$Y_n$	$\lambda_1$
3	$(-0.2091, 1.0000)^T$	7.8572
4	$(-0.3618, 1.0000)^T$	8.4182
5	$(-0.4362, 1.0000)^T$	8.7216
6	$(-0.4712, 1.0000)^T$	8.8724
7	$(-0.4871, 1.0000)^T$	8.9424
8	$(-0.4943, 1.0000)^T$	8.9742
9	$(-0.4975, 1.0000)^T$	8.9886
10	$(-0.4989, 1.0000)^T$	8.9950

which is converging to eigenvalue as 9 and corresponding eigenvector as  $(-1/2, 1)^T$ .

### Method of Deflation

**Example**

Consider a symmetric matrix

$$A = \begin{pmatrix} 5 & -2 \\ -2 & 8 \end{pmatrix}$$

Find all the eigenvalues of this matrix using power method together with method of deflation.

Start with  $X_0 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ ;  $X_1 = AX_0 = \begin{pmatrix} 3 \\ 6 \end{pmatrix} \mapsto Y_1 = 1/6 \begin{pmatrix} 1/2 \\ 1 \end{pmatrix}$   $X_2 =$

$AY_1 = \begin{pmatrix} 1/2 \\ 7 \end{pmatrix} \mapsto Y_2 = 1/7 \begin{pmatrix} 1/14 \\ 1 \end{pmatrix}$ ;  $X_3 = AY_2 = \begin{pmatrix} -1.6429 \\ 7.8572 \end{pmatrix}$

NPTEL ONLINE CERTIFICATION COURSE
20

So let us start with 1, 1. So using the power method and after going up to 10<sup>th</sup> iteration what I am getting that eigenvalue that is the dominant eigenvalue is converging to 9 and the corresponding eigenvector is converging to minus half 1. So hence one of the eigen value of this matrix, the bigger one in terms of absolute value is 9 and the corresponding eigenvector is minus 0.5, 1.

(Refer Slide Time: 28:42)

Here,

$$A_1 = A - \lambda_1 uu^T$$
$$= \begin{pmatrix} 5 & -2 \\ 2 & 8 \end{pmatrix} - 9/5 \begin{pmatrix} -1 \\ 2 \end{pmatrix} \begin{pmatrix} -1 & 2 \end{pmatrix} = 4/5 \begin{pmatrix} 4 & 2 \\ 2 & 1 \end{pmatrix}$$

Now if we start with  $X_0 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$ , we get  $X_2 = A_1 X_1 = 1/4.8 \begin{pmatrix} 1 \\ 1/2 \end{pmatrix}$

Which converge to eigenvalue  $\lambda_2 = 4$  and corresponding eigenvector as  $\begin{pmatrix} 1 \\ 1/2 \end{pmatrix}$

22

Now I apply this transformation deflation, so A will become A minus uhh B will become or A1, I have written A1 will become A minus lambda1 UU transpose. So after applying this my A1 is coming 4 upon 5 into (4, 2, 2, 1). Now again I will apply and from the method deflation theorem, one of the eigenvalue of this matrix will be 0 and the corresponding eigenvector will be V1 that is minus 0.5 and 1, which is corresponding to 9 or A. So by applying the power method again on this new matrix A1 starting with 1,1 we get X2 as this 1,1 upon 4.8 into 1 upon 1 by 2 and after going this way, we will see that the method is converging to 4 as the eigenvalue dominant eigenvalue of A1 and corresponding eigenvector as 1 and 0.5.

So hence this lambda2 equals to 4 is the dominant eigenvalue of A1, but it is the other eigenvalue that is the second eigenvalue of A and the corresponding eigenvector is 1 with and 0.5 as the two components. So hence using method of deflation with power method, we can calculate all the eigenvalues of a given matrix. So in this lecture we learn how to use power method for finding the dominant eigenvalue and corresponding eigenvector of a given matrix later on we have seen method of deflation if we apply together with power method, we can calculate other eigenvalues also, those are not dominant of the given matrix, thank you very much.
