Numerical differentiation part-V (Differentiation based on finite difference operators)

Welcome to the lecture series on numerical methods, in this lecture series we are just discussing this numerical differentiation based on interpolation and in the previous lecture I have discussed this like differentiation based on this Newton's divided difference interpolation and this error differentiation. And in this lecture we will just continue about this differentiation using this Central difference approximation and some of this finite difference approximation like based on finite difference operators.

(Refer Slide Time: 1:01)

Estimation of Error in Differentiation Formula based on Newton's Forward formula

The error term in Newton's forward difference formula we have,

$$R_{n+1}(x) = w(x) \frac{f^{n+1}(\xi)}{(n+1)!} = p(p-1)(p-2)\dots(p-n)h^{n+1} \frac{f^{n+1}(\xi)}{(n+1)!}, \quad x_0 \leq \xi \leq x_n$$

where $\min\{x_0, x_1, \dots, x_n\} < \xi < \max\{x_0, x_1, \dots, x_n\}$.

Differentiating with respect to x we get

$$R_{n+1}'(x) = h^{n+1} \frac{d}{dx} [p(p-1)(p-2)\dots(p-n)] \frac{f^{n+1}(\xi)}{(n+1)!} + h^{n+1} p(p-1)(p-2)\dots(p-n) \frac{d}{dx} \left[\frac{f^{n+1}(\xi)}{(n+1)!} \right]$$

So if you will just go for this error term analysis based on this Newton's forward difference formula, so usually these error terms for this Newton's forward difference approximation is written in the form like $R_{n+1}(x) = \omega \times f^{(n+1)}(\xi) / (n+1)!$, where this ω is usually written in the form like $x - x_0, x - x_1$ to $x - x_n$ here.

(Refer Slide Time: 1:36)

$$R_{n+1}(x) = w(x) \frac{f^{(n+1)}(\xi)}{(n+1)!}$$

where $w(x) = (x-x_0)(x-x_1) \dots (x-x_n)$

$$= p(p-1) \dots (p-n) h^{n+1} \frac{f^{(n+1)}(\xi)}{(n+1)!}$$

$$\min\{x_0, \dots, x_n\} \leq \xi \leq \max\{x_0, \dots, x_n\}$$

$$R_{n+1}'(x) = h^{n+1} \left[\frac{d}{dx} [p(p-1) \dots (p-n)] \frac{f^{(n+1)}(\xi)}{(n+1)!} + h^{n+1} \frac{d}{dx} \left(\frac{f^{(n+1)}(\xi)}{(n+1)!} \right) \cdot p(p-1) \dots (p-n) \right]$$

$$\frac{d}{dx} [p(p-1) \dots (p-n)] = \frac{dp}{dx} \frac{dp}{dx} = \frac{1}{h}$$

$x = x_0 + ph$

And in terms of p if you will just write then it can be written in the form like p into $p-1$ up to $p-n$ h to the power $n+1$ and f to the power $n+1$ zeta by $n+1$ factorial here. Since usually we are just expressing p as $x - x_0$ by h and that is why obviously we can just replace that one as in the form of $p-1$, $p-2$ that I have discussed in the previous lectures. So this Zeta well it can be determined as minima of x_0 to x_n this should be lies between zeta and maximum of x_0 to x_n here. So if you want to differentiate this error term here then this error term $R_{n+1}(x)$ can be written as $R_{n+1}'(x)$ which can be expressed as h to the power $n+1$ d by dx of p into $p-1$ up to $p-n$ f to the power $n+1$ Zeta by $n+1$ factorial here.

+ if you will just consider here $+ h$ to the power $n+1$ d by dx of your f to the power $n+1$ zeta by $n+1$ factorial into the product of p terms here that is p into $p-1$ up to $p-n$ here. Since Zeta is the function of x so that is why we have to differentiate this one with respect to x also here. So if you will just go for this like elimination of process here then we can just find that h to the power n it will just come since if you just see d by dx usually it can be written in the form like d by dp into dp by dx so dp by dx that will just give you 1 by h here. Usually we are just expressing x as $x_0 + ph$ here so that is why if you will just write this one as dp by dx here, which can be written as 1 by h here.

Obviously, this differentiation can be replaced as d by dp of the total function p into $p-1$ to $p-n$ into dp by dx here. So that is why this h term is coming and the final representation it can

be written in the form of like h to the power n if you will just write into d by dp of p into $p - 1$ up to $p - n$ f to the power $n + 1$ Zeta by $n + 1$ factorial + the remaining terms.

(Refer Slide Time: 4:56)

Estimation of Error in Differentiation Formula based on Newton's Forward formula

$$R_{n+1}'(x) = h^n \frac{d}{dp} [p(p-1)(p-2)\cdots(p-n)] \frac{f^{n+1}(\xi)}{(n+1)!}$$

$$+ h^{n+1} p(p-1)(p-2)\cdots(p-n) \frac{d}{dx} \{ f[x, x_0, x_1, \dots, x_n] \}$$

$$R_{n+1}'(x) = h^n \frac{d}{dp} [p(p-1)(p-2)\cdots(p-n)] \frac{f^{n+1}(\xi)}{(n+1)!}$$

$$+ h^{n+1} p(p-1)(p-2)\cdots(p-n) \frac{f^{n+2}(\xi_1)}{(n+2)!}$$

where $\min\{x_0, x_1, \dots, x_n\} < \xi, \xi_1 < \max\{x_0, x_1, \dots, x_n\}$

And if you will just apply this differentiation since in the earlier lecture we have derived this differentiation of f to the power $n + 1$ zeta there. So that is just completely expressed in the form of like divided difference from there, but here if we want to express this differentiation in the form of like Newton's forward difference operators here then this forward difference operators can be replaced here this f to the power $n + 1$ zeta as Δ to the power $n + 1$ y_0 by $n + 1$ factorial here.

Obviously we can just express this one in Delta form here since in all of these lectures I have just explained that this tabular value is known to us but the function is not known explicitly to us, so that is why if these tabular values has been given to us directly we can just approximate this error term by considering all of these tabular values even if this differentiation can be approximated by using this forward difference table here. And if we will just write this difference terms here in terms of Newton's forward difference operator so this can be written in the form of like Δ to the power $n + 1$ y_0 divided by $n + 1$ factorial into h to the power $n + 1$ here.

(Refer Slide Time: 6:22)

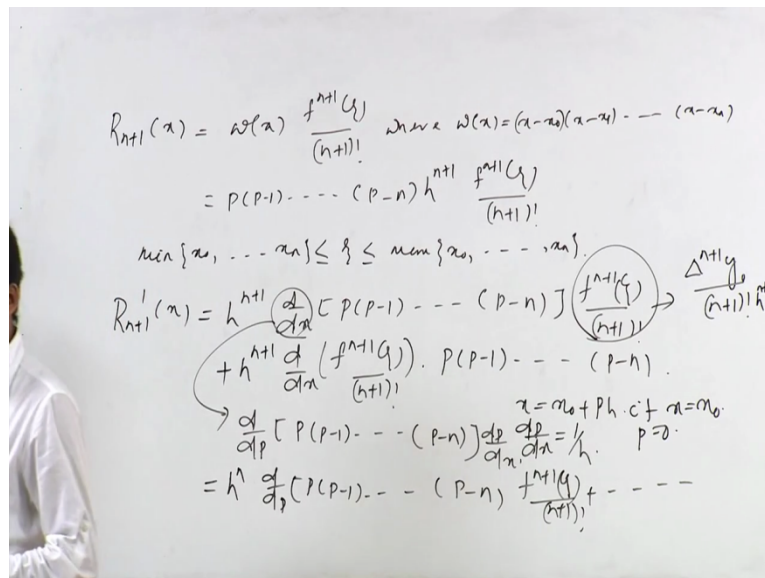

Estimation of Error in Differentiation Formula based on Newton's Forward formula

Assuming that $f^{n+1}(x)$ and $f^{n+2}(x)$ do not vary strongly for small h , therefore we get

$$R_{n+1}'(x) = h^n \frac{d}{dp} [p(p-1)(p-2)\cdots(p-n)] \frac{\Delta^{n+1}y_0}{(n+1)!h^{n+1}} + h^{n+1} p(p-1)(p-2)\cdots(p-n) \frac{\Delta^{n+2}y_0}{(n+2)!h^{n+2}}$$

$$= \frac{d}{dp} [p(p-1)(p-2)\cdots(p-n)] \frac{\Delta^{n+1}y_0}{(n+1)!h} + p(p-1)(p-2)\cdots(p-n) \frac{\Delta^{n+2}y_0}{(n+2)!h}$$

NPTEL ONLINE CERTIFICATION COURSE
5

Handwritten derivation of the error formula for Newton's forward difference method. The derivation starts with the Newton's forward difference formula for the $(n+1)$ th order polynomial:

$$R_{n+1}(x) = \omega(x) \frac{f^{n+1}(\xi)}{(n+1)!}$$

where $\omega(x) = (x-x_0)(x-x_1)\cdots(x-x_n)$. The derivative is then taken with respect to x :

$$R_{n+1}'(x) = \frac{d}{dx} \left[\omega(x) \frac{f^{n+1}(\xi)}{(n+1)!} \right]$$

Using the product rule, this becomes:

$$R_{n+1}'(x) = \omega'(x) \frac{f^{n+1}(\xi)}{(n+1)!} + \omega(x) \frac{d}{dx} \left[\frac{f^{n+1}(\xi)}{(n+1)!} \right]$$

The first term is evaluated at $x = x_0$ where $\omega(x_0) = 0$, leaving:

$$R_{n+1}'(x_0) = \omega'(x_0) \frac{f^{n+1}(\xi)}{(n+1)!}$$

The derivative of $\omega(x)$ at x_0 is:

$$\omega'(x_0) = p(p-1)(p-2)\cdots(p-n)h^n$$

where $p = \frac{x - x_0}{h}$. Substituting this back into the error formula gives the final result:

$$R_{n+1}'(x_0) = h^n \frac{d}{dp} [p(p-1)(p-2)\cdots(p-n)] \frac{f^{n+1}(\xi)}{(n+1)!h}$$

So once it can be expressed in this divided difference form sorry this forward difference from here, then we can just obtain this f to the power $n + 2$ zeta term since we will if you will just take the differentiation of f to the power $n + 1$ zeta by $n + 1$ factorial, so that will just give you f to the power $n + 2$ zeta by $n + 1$ factorial zeta dash x there so that is why it can be expressed in the form of like Δ to the power $n + 2$ y_0 by $n + 2$ factorial h to the power and $+ 2$ there. And obviously if you just write all these terms here then this can be expressed as d by dp of p into $p - 1$ into $p - 2$ up to $p - n$ Δ to the power $n + 1$ y_0 by $n + 1$ factorial into $h + p$ into $p - 1$ up to $p - n$ Δ the power $n + 2$ y_0 by $n + 2$ factorial into h there.

Since h to the power $n + 1$ is there and it can just cancel it out with h to the power $n + 2$ and 1 by h is left over there. Since at $x = x_0$ obviously we are just obtaining $p = 0$ if $x = x_0$ there

and at that point we can just write this error term differentiation that is R_{n+1} of $n+1$ dash of x_0 this can be written as -1 whole to the power n factorial Δ to the power $n+1$ y_0 by $n+1$ factorial h here.

(Refer Slide Time: 7:48)

Estimation of Error in Differentiation Formula based on Newton's Forward formula

Since at $x = x_0$ i.e. $p=0$ the second term of the right side become zero

$$R_{n+1}'(x_0) = (-1)^n n! \frac{\Delta^{n+1} y_0}{(n+1)! h}$$

Since $\frac{d}{dp} [p(p-1)(p-2)\dots(p-n)]$ at $p=0$ is $(-1)^n n!$

$$R_{n+1}'(x_0) = (-1)^n \frac{\Delta^{n+1} y_0}{(n+1) h}$$

6

Since if you will just see this x function here, that is d by dp of p into $p-1$ to $p-n$ at $p=0$ is nothing but -1 whole to the power n n factorial here. And that is why this R_{n+1} dash x_0 can be written as -1 whole to the power n Δ to the power $n+1$ y_0 by $n+1$ into h also sometimes. Since $n+1$ factorial it just takes the product of n factorial into $n+1$ so $n+1$ remained over there. So based on this approximation we will just go for computation of errors in the Newton's forward interpolation formula.

(Refer Slide Time: 8:25)

Error Computation in Newton Forward Interpolation

From the following the data find y' and y'' at $x=2.00$ using up to third difference only

x	2.00	2.20	2.40	2.60	2.80	3.00
y	0.6932	0.7885	0.8755	0.9555	1.0296	1.0986

Also compute the error term.

TABLE

x	y	1 st diff	2 nd diff	3 rd diff	4 th diff
2.00	0.6932	0.0953	-0.0083	0.0013	-0.0002
2.20	0.7885	0.0870	-0.0070	0.0011	-0.0003
2.40	0.8755	0.0800	-0.0059	0.0008	
2.60	0.9555	0.0741	-0.0051		
2.80	1.0296	0.0690			
3.00	1.0986				

7

So for that if you just consider a table like x is prescribed at 2, 2.20, 2.40, 2.60, 2.80 and 3.00 here and corresponding y values if it is just to be given like 0.6932, 0.7885, 0.8755, 0.9555, 1.0296, 1.0296 here. Then the first difference if you just compute here that is the difference of $0.7885 - 0.6932$ since already we have derived lot of forward difference approximation in tabular form so that is why it is easy to compute since we will just consider this difference of like 2 values corresponding tabular values like associated to each other there. So $0.7885 - 0.6932$ this just gives you the value as 0.0953, difference of $0.5755 - 0.7885$ this is just giving you the values as 0.0870, the difference of these 2 values $0.8755 - 0.9555$ sorry this is $0.9555 - 0.8755$ this is just giving you 0.0800.

Then $1.0296 - 0.9555$ this is just giving you 0.0741, then the difference of $1.0986 - 1.0296$ this is just giving you 0.0690 here. Similarly we can just obtain the second differences here, third differentiation and fourth differentiation.

(Refer Slide Time: 10:12)

Error Computation in Newton Forward Interpolation

At the tabular point x_0 up to 3rd differences,

$$\frac{dy}{dx} = \frac{1}{h} \left(\Delta y_0 - \frac{1}{2} \Delta^2 y_0 + \frac{1}{3} \Delta^3 y_0 \right) \text{ and } \frac{d^2 y}{dx^2} = \frac{1}{h^2} (\Delta^2 y_0 - \Delta^3 y_0)$$

Here $x_0 = 2.00$; $p = 0$; $h = 0.20$

$$y'(2.00) = \frac{1}{0.2} \left(0.0953 - \frac{1}{2}(-0.0083) + \frac{1}{3}(0.0013) \right) = 0.4994$$

and $y''(2.00) = \frac{1}{(0.2)^2} (-0.0083 - 0.0013) = -0.24$

Therefore the **error term** is $R_4'(x_0) = \left| (-1)^3 \frac{\Delta^4 y_0}{4h} \right|$

$$R_4'(2.00) = \left| -\frac{1}{0.20} \times \frac{-0.0002}{4} \right| = 0.00025$$

So based on this if the tabular point is asked you to compute up to third differences and then obtain this error term then we obviously we can just write this one as the fourth term there since the divided difference up to third order can be approximated in a polynomial form there, immediate next term can be considered as the error term for that position therefore the error term can be written in the form like R_4 of x here. So usually this R_4 of x_0 it can be written in the form of like if you will just see here, $\Delta^4 y_0$ can be written as like $\Delta^4 y_0$ to the power 4 of Δ by 4 factorial so specially it can be written.

(Refer Slide Time: 11:00)

$$\begin{aligned}
 R_4(x) &= \omega(x) \frac{f^{(4)}(x)}{4!} \\
 R_4'(x) &= (-1)^{n-3} \frac{\Delta^4 y_0}{(3+1)h} \\
 R_4'(x_0) &= (-1)^3 \frac{\Delta^4 y_0}{4h} \\
 &= \left| -\frac{1}{h} \times \frac{1}{4} \times \Delta^4 y_0 \right| \\
 &= \left| -\frac{1}{0.20} \times \frac{-0.002}{4} \right|
 \end{aligned}$$

If you will just write in a complete form here, so are 4 of x can be written as Omega of x f to the power 4 of zeta by 4 factorial here. And in the differentiation form if you just write R 4 dash of x, this can be written as -1 whole to the power n that is $n = 3$ there and then we can just write Del to the power 4 of y_0 by $n + 1$ this means n is 3 here so $3 + 1$ into h here. So obviously if you will just put directly in the tabular values here, so are 4 dash of x_0 this can be written as -1 whole to the power 3 Del to the power 4 of y_0 by 4 h here.

And at that point exactly if the error is asked suppose at $x_0 = 2.00$ here since the beginning of the tabular values is 2.00 so R 4 dash of 2.00 it can be written as like -1 whole to the power 3 so that will just give you $-$ sign here and this your h size is 0.20 here so that is why -1 by 0.20 into 1 by 4 into your Del to the power 4 value that is just giving you -0.002 here. So obviously if I will just write here this can be written in the form of like absolute values of -1 by h into 1 by 4 into Del to the power 4 of y_0 here and this is nothing but -1 by 0.20 into since this value is just giving you like -0.0002 hereby 4 so this can be written in this form here.

(Refer Slide Time: 13:10)

Differentiation Based on Finite difference Operators

We can define the relation

$$Ef(x) = f(x+h) = f(x) + hf'(x) + \frac{h^2}{2!} f''(x) + \frac{h^3}{3!} f'''(x) + \dots$$

$$= \left(1 + hD + \frac{(hD)^2}{2!} + \frac{(hD)^3}{3!} + \dots \right) f(x) = e^{hD} f(x)$$

in which $D = d/dx$ is called the differential operator.

Symbolically it can be written of the form as

$$e^{hD} = E \text{ or } hD = \log E = \begin{cases} \log(1 + \Delta) = \Delta - \frac{1}{2}\Delta^2 + \frac{1}{3}\Delta^3 - \dots \\ -\log(1 - \nabla) = \nabla + \frac{1}{2}\nabla^2 + \frac{1}{3}\nabla^3 + \dots \end{cases}$$

And obviously this value is just giving you 0.00025 here, so if you will just define this like differentiation using like finite difference operators, so finite difference operator means we can just consider that shift operator here, shift operator is usually expressed in the form of e of f of x here so e of f of x is usually written in the form like f of $x + h$ here and f of $x + h$ can be expressed in the form of Taylor series as hD of f of x , hD whole square by factorial 2 f double dash of x + rest of the terms. And usually it can be represented as $1 + hD + hD$ whole square by factorial 2 + this one into f of x here, and obviously it can be written in the form of e to the power hD f of x here.

And finally we are just expressing this shift operator E as e to the power hD here. That we have just expressed in the earlier lectures that $d = d$ by dx here that is nothing but the derivative here and which can be expressed in the form of like forward difference operator, backward difference operator, centre difference operator, in any form we can just express this shift operator. So based on that we can just say that these operators can also be expressed in the differential operator form also there that means that d by dx can be expressed in the form of like Delta, Nabla or Centre difference operators like small Delta and average operators like Mu there, et cetera.

(Refer Slide Time: 14:56)

Differentiation Based on Finite difference Operators

Also we can written as

$$\delta = (I_t^{1/2} - I_t^{-1/2}) = (e^{hD/2} - e^{-hD/2}) = 2 \sinh(hD/2)$$

$$\Rightarrow hD = 2 \sinh^{-1}(\delta/2) = \delta - \frac{1^2}{2^2 \cdot 3!} \delta^3 + \dots$$

and $hf'(x_k) = hDf(x_k) = \begin{cases} \Delta f_k - \frac{1}{2} \Delta^2 f_k + \frac{1}{3} \Delta^3 f_k - \dots \\ \nabla f_k + \frac{1}{2} \nabla^2 f_k + \frac{1}{3} \nabla^3 f_k + \dots \\ \delta f_k - \frac{1^2}{2^2 \cdot 3!} \delta^3 f_k + \frac{1^2 \cdot 3^2}{2^4 \cdot 5!} \delta^5 f_k - \dots \end{cases}$

NTEL ONLINE
CERTIFICATION COURSE
10

So if you just express these differential operators in the form of like forward difference operator like first difference if you just consider for this Newton's forward difference operator at a point k then we can just write h D of f of x k can be expressed in the forward difference form as $\Delta f_k - \frac{1}{2} \Delta^2 f_k + \frac{1}{3} \Delta^3 f_k - \dots$ up to finite number of terms. Similarly, this divided difference sorry this differential operator can also be expressed in a backward difference form that can be expressed as $\nabla f_k + \frac{1}{2} \nabla^2 f_k + \frac{1}{3} \nabla^3 f_k + \dots$ so likewise we can also express.

And also in central different approximation this can be written as $\delta f_k - \frac{1^2}{2^2 \cdot 3!} \delta^3 f_k + \frac{1^2 \cdot 3^2}{2^4 \cdot 5!} \delta^5 f_k - \dots$ so likewise we can just express this differential operators in various products form. So in the same way also we can just express this second order differentiation also, this means that second order differentiation we can just consider that one as $h^2 f''(x_k)$ and this is nothing but h D you can just write, so h D can be written as like again one more differentiation we can just consider.

(Refer Slide Time: 16:13)

Differentiation Based on Finite difference Operators

$$h^2 f''(x_k) = h^2 D^2 = \begin{cases} \Delta^2 f_k - \Delta^3 f_k + \frac{11}{12} \Delta^4 f_k - \dots \\ \nabla^2 f_k + \nabla^3 f_k + \frac{11}{12} \nabla^4 f_k + \dots \\ \delta^2 f_k - \frac{1}{12} \delta^4 f_k + \frac{1}{90} \delta^6 f_k - \dots \end{cases}$$

In general we can write,

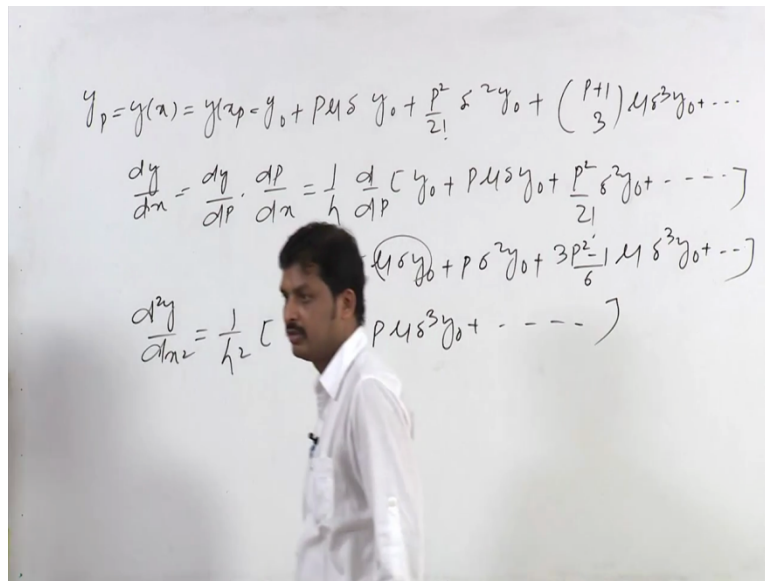

$$h^r D^r = \begin{cases} \Delta^r - \frac{1}{2} r \Delta^{r+1} + \frac{r(3r+5)}{24} \Delta^{r+2} - \dots \\ \nabla^r + \frac{1}{2} r \nabla^{r+1} + \frac{r(3r+5)}{24} \nabla^{r+2} + \dots \\ \delta^r - \frac{r}{24} \delta^{r+2} + \frac{r(5r+22)}{5760} \delta^{r+4} - \dots \end{cases}$$

NPTEL ONLINE CERTIFICATION COURSE
11

This is function of Newton's forward difference operators, backward difference operators or central difference operators. So if you will just consider these operators once more here, this can be expressed as Delta square of f_k - Delta cube of f_k + 11 by 12 Delta to the power 4 of x_k for forward difference operators. Similarly we can just express this one in backward difference operators that is in the form of Nabla square f_k + nabla cube f_k + 11 by 12 Nabla by 4 of f_k + all other terms.

And in general form if you will express this one as h to the power r D to the power r here, so this can be expressed as Delta to the power r - half r Delta to the power $r + 1$ + r into $3r + 5$ by 24 Delta to the power $r + 2$ - all other terms are there. Similarly if you just take this backward difference operator, that it can be expressed as Nabla 2 by r + half r Nabla to the power $r + 1$ + r into $3r + 5$ by 24 Nabla to the power $r + 2$ + all other terms. And if you will just use this central difference operative to express this r th order derivative of any function then it can be expressed as small Delta to the power r - r by 24 small Delta to the power $r + 2$ + r into $5r + 22$ by 5760 small Delta to the power $r + 4$ - all other terms it can be expressed up to finite number of terms.

(Refer Slide Time: 18:44)

$$y_p = y(x) = y(x_p) = y_0 + p \mu \delta y_0 + \frac{p^2}{2!} \delta^2 y_0 + \left(\frac{p^3}{3} \right) \mu \delta^3 y_0 + \dots$$

$$\frac{dy}{dx} = \frac{dy}{dp} \cdot \frac{dp}{dx} = \frac{1}{h} \frac{d}{dp} \left[y_0 + p \mu \delta y_0 + \frac{p^2}{2!} \delta^2 y_0 + \dots \right]$$

$$\frac{d^2 y}{dx^2} = \frac{1}{h^2} \left[\mu \delta^2 y_0 + p \delta^3 y_0 + \frac{3p^2 - 1}{6} \mu \delta^4 y_0 + \dots \right]$$

So next we will just go for central different approximation how we can use just this differentiation for central differential approximation like Stirling formula and Bessel's formula here. For this Stirling's formula already we have derived this expression for Stirling formula that is expressed in the form of like the central different approximation for Stirling formula usually it is written in the form of like y_p or y of x or y of x_p can be written as $y_0 + p \mu \delta y_0 + \frac{p^2}{2!} \delta^2 y_0 + \frac{1}{3} \mu \delta^3 y_0 +$ all other terms are there.

So if you just differentiate with respect to x here that can be written as dy by dx this as 1 by h into usually this expression can be written in the form like dy by dp into dp by dx so that is why dp by dx is nothing but 1 by h and d by dp of your expression $y_0 + p \mu \delta y_0 + \frac{p^2}{2!} \delta^2 y_0 +$ all other terms are there. If you will just differentiate this one with respect to p here this can just give you 1 by h , first term it will just give you 0 , second term $\mu \delta y_0$ here $+ 2p$ by 2 factorial so $p \delta^2 y_0 +$ the third factorial if you just take this one that will just give $3p^2 - 1$ by $6 \mu \delta^3 y_0 +$ all other terms.

And if you just take one more differentiation of this scheme here that is d^2 by dx^2 , it can be written as 1 by h^2 so first term is just stated as a constant here then it will just start from this immediate next term so it is δ^2 of y_0 here so 3 into 2 into p here so 6 by 6 cancel it out so that is why it can be written as $p \mu \delta^3 y_0 +$ rest of the terms here.

(Refer Slide Time: 20:27)

Differentiation Based on Central difference Operators

Bessel's formula:

$$y_p = y(p) = \mu y_{1/2} + \left(p - \frac{1}{2}\right) \delta y_{1/2} + \left(\frac{p}{2}\right) \mu \delta^2 y_{1/2} + \left(\frac{p}{2}\right) \frac{\left(p - \frac{1}{2}\right)}{3} \delta^3 y_{1/2} + \left(\frac{p+1}{4}\right) \mu \delta^4 y_{1/2} + \dots$$

Differentiating with respect to x we get

$$\frac{dy}{dx} = \frac{1}{h} \left(\delta y_{1/2} + \frac{2p-1}{2} \mu \delta^2 y_{1/2} + \frac{6p^2-6p+1}{12} \mu \delta^3 y_{1/2} + \frac{2p^3-3p^2-p+1}{12} \mu \delta^4 y_{1/2} + \dots \right)$$

$$\frac{d^2 y}{dx^2} = \frac{1}{h^2} \left(\mu \delta^2 y_{1/2} + \frac{2p-1}{2} \delta^3 y_{1/2} + \frac{6p^2-6p-1}{12} \mu \delta^4 y_{1/2} + \dots \right)$$

NPTEL ONLINE
CERTIFICATION COURSE
13

Similarly we can just use this formulation for like Bessel's formula here so Bessel's formula usually it is expressed as like $y_p = y$ of x_p that as μy of half here so if you just write this one as y_p in Bessel's formula here, this is for Stirling's formula here.

(Refer Slide Time: 21:19)

Stirling's formula

$$y_p = y(x) = y_0 + p \mu \delta y_0 + \frac{p^2}{2!} \delta^2 y_0 + \left(\frac{p+1}{3}\right) \mu \delta^3 y_0 + \dots$$

$$\frac{dy}{dx} = \frac{dy}{dp} \cdot \frac{dp}{dx} = \frac{1}{h} \frac{d}{dp} \left[y_0 + p \mu \delta y_0 + \frac{p^2}{2!} \delta^2 y_0 + \dots \right]$$

$$= \frac{1}{h} \left[\mu \delta y_0 + p \delta^2 y_0 + \frac{3p^2-1}{6} \mu \delta^3 y_0 + \dots \right]$$

Bessel's formula

$$y_p = \mu y_{1/2} + \left(p - \frac{1}{2}\right) \delta y_{1/2} + \left(\frac{p}{2}\right) \mu \delta^2 y_{1/2} + \left(\frac{p}{2}\right) \frac{\left(p - \frac{1}{2}\right)}{3} \delta^3 y_{1/2} + \dots$$

$$\frac{dy}{dx} = \frac{1}{h} \left[\dots \right]$$

For Bessel's formula usually this y_p is written in the form like μy of half + $p - \frac{1}{2}$ Delta y of half here + p^2 μ Delta square y of half + p^2 $p - \frac{1}{2}$ by 3 Delta cube of y of half here so + all other terms. If you will just take the differentiation here, this same form we can just write dy by dx this as $\frac{1}{h}$, the first-term we can just take here as like Delta y of half here so then + $2p - 1$ by 2 μ Delta square y of half then $6p^2 - 6p + 1$ by 12 μ Delta cube of y of half + all other terms there. Similarly if you just take the second differentiation

here that can be written in the form of $1 \text{ by } 1 \text{ by } h^2 \mu \Delta^2 y$ of half since if you will just take the differentiation of second term here since first-term is constant here.

Second term if you just take that can be represented a $\mu \Delta^2$ of half here + 6 p square means $12 p$ – it is like 6 here so that is why $2 p - 1 \text{ by } 2 \Delta^3$ of y of half + all other terms we can just write.

(Refer Slide Time: 22:42)

Example on Central Difference operators						
From the following the data find y' and y'' at $x=2.40$ and 2.80 using appropriate CD formula						
x	1.00	1.50	2.00	2.50	3.00	3.50
y	1.000	1.1447	1.2599	1.3572	1.4422	1.5183
TABLE						
x	y	1 st diff	2 nd diff	3 rd diff	4 th diff	5 th diff
1.00	1.000	0.1447	-0.0295	0.0116	-0.0060	0.0038
1.50	1.1447	0.1152	-0.0179	0.0056	-0.0022	
2.00	1.2599	0.0973	-0.0123	0.0034		
2.50	1.3572	0.0850	-0.0089			
3.00	1.4422	0.0761				
3.50	1.5183					

So based on this if you just go for example here since central different approximation usually it can be approximated at centre of the table here where for both of these formulas we have defined this approximately parameters so that where it can be used. So in that regard if we will just consider this table as like x is defined as 1.00, 1.50, 2.00, 2.50, 3.00, 3.50, all are equally spaced points with space size 0.5 suppose with this corresponding y values as 1, 1.447, 1.2599, 1.3572, 1.4422, 1.5183 here, then if you just use these first differences for all these values we can just obtain this one as 0.1447, 0.1152, 0.0973, 0.0850, 0.0761 for first differences.

For second difference if you will just take the differences of immediate next terms; 0.1152 - 0.1447 here then that will just give you - 0.0295 here. Similarly if you just take the difference of 0.0973 - 0.1152, this will just give you - 0.0179 here. And if you will take the difference of 0.0850 - 0.0973 this will just give you - 0.0123 here, if you just take the difference of 0.0761 and 0.0850 that will just give you - 0.0089. Similarly we can just define this third difference, 4th differences and 5th differences here since we have 6 points so that is why we can just consider the differences up to 5th order here.

(Refer Slide Time: 24:49)

Example on Central Difference operators

At $x=2.40$, we chose the initial point $x_0=2.50$, then
 $p=(2.40-2.50)/0.50=-0.2$, since $h=0.5$. Therefore $-0.25 < p < 0.25$,
 thus Stirling's formula should be used.

$$y'(x) = \frac{1}{h} \left(\mu \delta y_0 + p \delta^2 y_0 + \frac{3p^2 - 1}{6} \mu \delta^3 y_0 \right)$$

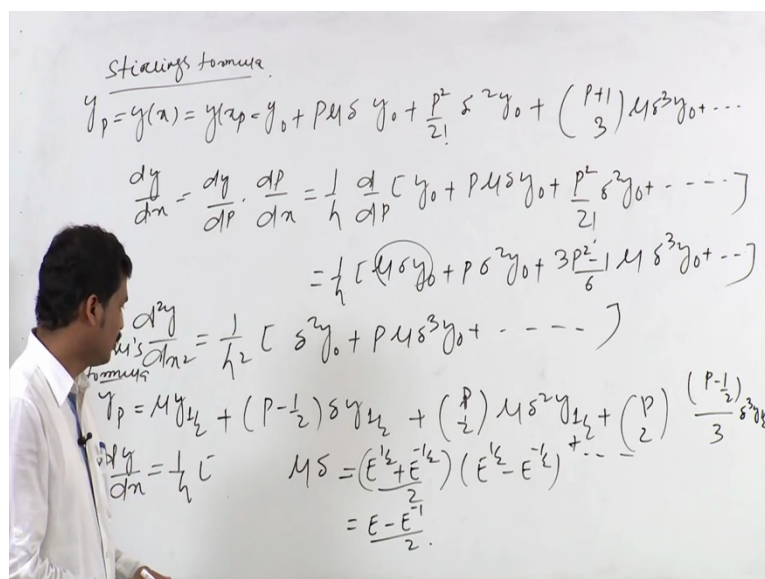

$$y'(2.40) = \frac{1}{0.5} \left(\frac{0.0973 + 0.0850}{2} + (-0.2)(-0.0123) + \frac{3(-0.2)^2 - 1}{6} \frac{0.0056 + 0.0034}{2} \right)$$

$$= 2[0.09115 + 0.00246 - 0.00029] = 0.1866$$

15

And if it is asked to use this Stirling's formula in Bessel's formula for this error approximation up to suppose third order term here so up to third order we can just consider and immediate next term we can just consider the error form here. First we have computed this derivative at that values like suppose the values asked you to compute this derivative as 2.40 here so that is why we can just put here y' as x is defined as 1 by x $\mu \delta y_0 + p \delta^2 y_0 + \frac{3p^2 - 1}{6} \mu \delta^3 y_0$ here so that is why we can just use h as 0.5 here, 1 by 0.5 so average of these 2 this is like $\mu \delta$ can be written as like your values, we can just write δy of $1 + \delta y_0$ by 2 there so that is why it can be written as $0.0973 + 0.0850$ by 2 there.

(Refer Slide Time: 25:47)

Stirling's formula.

$$y_p = y(x) = y_0 + p\mu\delta y_0 + \frac{p^2}{2!}\delta^2 y_0 + \left(\frac{p^3}{3}\right)\mu\delta^3 y_0 + \dots$$

$$\frac{dy}{dx} = \frac{dy}{dp} \cdot \frac{dp}{dx} = \frac{1}{h} \frac{d}{dp} \left[y_0 + p\mu\delta y_0 + \frac{p^2}{2!}\delta^2 y_0 + \dots \right]$$

$$= \frac{1}{h} \left[\mu\delta y_0 + p\delta^2 y_0 + \frac{3p^2 - 1}{6} \mu\delta^3 y_0 + \dots \right]$$

$$\frac{d^2 y}{dx^2} = \frac{1}{h^2} \left[\delta^2 y_0 + p\mu\delta^3 y_0 + \dots \right]$$

$$y_p = \mu y_{1/2} + \left(p - \frac{1}{2}\right) \delta y_{1/2} + \left(\frac{p^2}{2}\right) \mu \delta^2 y_{1/2} + \left(\frac{p^3}{6}\right) \delta^3 y_{1/2} + \dots$$

$$\mu \delta = \frac{(E^{1/2} + E^{-1/2})}{2} (E^{1/2} - E^{-1/2}) = \frac{E - E^{-1}}{2}$$

Directly you can just express in the form of like if we want to write this one as $\mu\Delta$ here so $\mu\Delta$ can be written as $E^{\frac{1}{2}} + E^{-\frac{1}{2}}$ by 2 into $E^{\frac{1}{2}} - E^{-\frac{1}{2}}$ here. If you just take the product here we can just obtain this one as $E - E$ of -1 by 2 here, so obviously we can just write this one as $f(x+h) - f(x-h)$ by 2 so that is why we are just using this differentiation if you will just see as $0.0973 + 0.0850$ here by 2. So using all these we can just obtain these values as 0.1866 here. The second order formula if you will just use here that is $y''(x)$ here so $y''(x)$ it is just given as $\frac{1}{h^2} \Delta^2 y_0 + p \mu \Delta^3 y_0 + \frac{6p^2 - 1}{12} \Delta^4 y_0$ + all other points.

(Refer Slide Time: 26:49)

Example on Central Difference operators

The second order formula is

$$y''(x) = \frac{1}{h^2} \left(\delta^2 y_0 + p \mu \delta^3 y_0 + \frac{6p^2 - 1}{12} \delta^4 y_0 \right)$$

Substituting the values we get

$$y''(2.40) = \frac{1}{0.5^2} \left(-0.0123 + (-0.2) \frac{0.0056 + 0.0034}{2} + \frac{6(-0.2)^2 - 1}{12} (-0.0022) \right)$$

$$= 4[-0.0123 - 0.0008 + 0.00014] = -0.0518$$

NPTEL ONLINE CERTIFICATION COURSE
16

So similarly h is given as 0.5 here so that is why 1 by 0.5 square here we have considered and $\Delta^2 y_0$ that is nothing but the second order differentiation of this forward difference table also so that is why it can be considered as -0.0123 here + p value that is given as -0.2 into the average of Δ^3 values we have just considered here and rest of the values can be defined in the same form here and finally we are just obtaining $y''(2.40)$ as -0.0518 here. And if you just use this formula for the point 2.80 here then we can just use Bessel's formula for that since p range is lying between 0.25 to 0.75 within that range specially we can use the Bessel's formula.

(Refer Slide Time: 27:23)

Example on Central Difference operators

At $x=2.80$, we chose the initial point $x_0=2.50$, then
 $p=(2.80-2.50)/0.50=0.6$, since $h=0.5$. Therefore $0.25 < p < 0.75$,
 thus we use Bessel's formula should be used.

$$y'(x) = \frac{1}{h} \left(\delta y_{1/2} + \frac{2p-1}{2} \mu \delta^2 y_{1/2} + \frac{6p^2-6p+1}{12} \mu \delta^3 y_{1/2} \right)$$

$$y'(2.80) = \frac{1}{0.5} \left(0.0850 + \frac{2 \times 0.6 - 1}{2} \frac{-0.0089 - 0.0123}{2} + \frac{6(0.6)^2 - 6 \times 0.6 + 1}{12} 0.0034 \right)$$

$$= 2[0.0850 - 0.00106 - 0.00012] = 0.1676$$

NPTEL ONLINE CERTIFICATION COURSE
17

So for that if you will just find here the derivative of y of x is usually written as 1 by h Delta Y of half $+$ to $p - 1$ by 2 Mu square y of half $+$ $6p^2 - 6p + 1$ by 12 Mu Delta cube y of half here. So if you just put these values like 1 by 0.5 , $0.0850 + 2$ into $0.6 - 1$, so all other terms it can be placed accordingly. Then we can just obtain this first order derivative at 2.80 at 0.1676 here so the second order formula if you just use here that is in the form of like 1 by h square Mu Delta square Y of half $+$ $2p - 1$ by 2 Delta cube y of half so then we can just obtain at the point 2.80 as since already we have obtained that h as 0.5 here.

(Refer Slide Time: 28:33)

Example on Central Difference operators

The second order formula is

$$y''(x) = \frac{1}{h^2} \left(\mu \delta^2 y_{1/2} + \frac{2p-1}{2} \delta^3 y_{1/2} \right)$$

Substituting the values we get

$$y''(2.80) = \frac{1}{0.5^2} \left(\frac{-0.0089 - 0.0123}{2} + \frac{2 \times 0.6 - 1}{2} 0.0034 \right)$$

$$= 4[-0.0106 + 0.00034] = -0.0410$$

NPTEL ONLINE CERTIFICATION COURSE
18

So that is why this can be written as 1 by h square means 1 by 0.5 whole square so then Mu Delta square y of half if you will just take Mu as average value here so Delta square half we

can just write this one as Delta of Delta of y of half and we can obtain the values in the form of like $-0.089 - 0.0123$ divided by 2 here $+ 2p - 1$ so p is given as 0.6 here, 2 into $0.6 - 1$ by 2 into Delta cube y of half this is nothing but directly we can just obtain from this divided difference formula here sorry this forward difference formula and the final value is obtained as -0.0410 as this one, thank you for listening this lecture.
