Lecture No 31
Numerical Integration Part 1

Welcome to the lecture series of numerical methods. In the last lecture we have discussed about numerical differentiation and today we will start about numerical integration. So in numerical integration we will just deal different kinds of interpolation formulas and how we can just integrate this polynomial or this function with using this interpolation formulas.

So specifically the advantage of this numerical integration is that if we will have this specific nodal points with its tabular values then at that point if the function is not known to us explicitly we can use this numerical integrations to evaluate this functional values at all of this point or whatever wherever this points are asked to evaluate.

(Refer Slide Time: 01:30)

So first we will just go for this introduction that where we are just observing this difficulties of the solving problems in integration and why we are just going for this numerical integration. Then we will just go for this methodology for numerical integrations and obviously for this lecture we will just go upto the rectangular rule that how we can just use this rectangular rule to evaluate this integration.

(Refer Slide Time: 01:44)

Introduction

History of Integration:

- ❑ **Archimedes** is the founder of surface areas and volumes of solids such as the sphere and the cone. His integration method was very modern.
- ❑ **Gauss** was the first to make graph of integrals.
- ❑ **Leibniz** and **Newton** discover calculus and found that differentiation and integration undo each other.

IIT ROORKEENPTEL ONLINE
CERTIFICATION COURSE3

So specifically if you will just go for the history of integration you can just find that Archimedes has developed this integration to find the surface area and volumes of solids and this integration method was very modern nowadays. And since earlier it was just developed to calculate this area or volume or solids volume of solids in the spear or in cones. Gauss was first introduced to make the integrals in a graphical sense this means that graphs for integrals he has developed and Leibniz and Newton discovered the calculus and found this differentiation in integration which are converts to each other.

(Refer Slide Time: 02:33)

Introduction

How integration applies to the real world?

- ❑ Integration was used to design the PETRONAS Towers making it stronger
- ❑ Many differential equation were used in the designing of the Sydney Opera House
- ❑ Finding areas under curved surface, Centers of mass, displacement and velocity, and fluid flow are other uses of integration

IIT ROORKEENPTEL ONLINE
CERTIFICATION COURSE4

So integration was used to design or it can be applicable to many fields of science and engineering if you will just see. And here I am just showing some of this modern infrastructures where this integration was use like PETRONAS Tower and Sydney Opera House or finding this curves under the Centre of mass, displacement, velocity and fluid flows, specifically without integration and derivative we cannot solve such type of problems.

(Refer Slide Time: 03:03)

Introduction

What is the integration?

Integration is the process of evaluating an indefinite integral or a definite integral.

$\int f(x) dx$

Integral sign

Integrand

x is called the variable of integration

Definite Integral

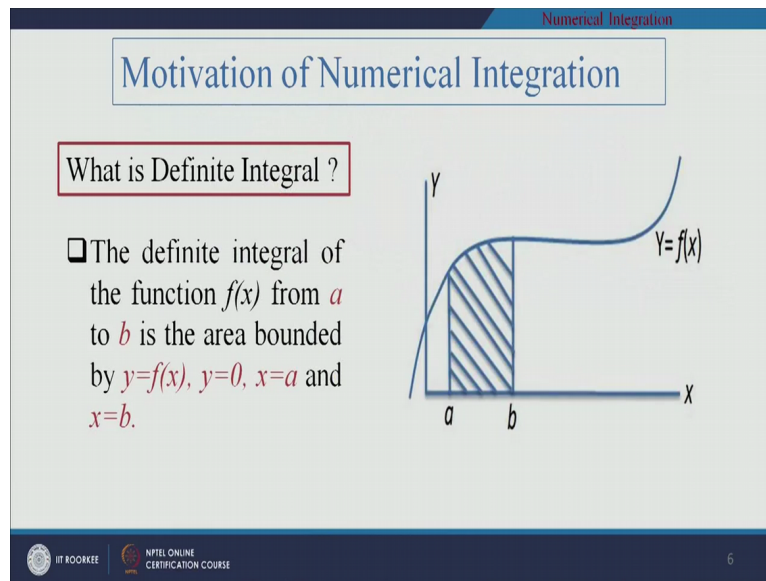

Indefinite Integral

$\rightarrow \int_a^b f(x) dx$
 $\rightarrow \int_a^{\infty} f(x) dx$

5

So if you will just go for this integration, if somebody asked what is integration, so then especially we are just putting curve sign and which is just giving a parametric region where we want to evaluate this integration or calculate this areas or surfaces or volume bounded within that surface. And if we are just defining this integrals, so integrals are of 2 types, first it is called definite integrals, where this end point should be finite and we can just easily position this points. And next is that indefinite integrals if some ranges are infinite then especially it is called indefinite integral, where it is difficult to evaluate the functional values within that range.

(Refer Slide Time: 03:46)

So in such cases so if you will just go for like finite definite integral or finite range integrals. So especially we are just defining a range there, y has a range like y equals to like 0 to some range suppose and x has a range like x equals to 0 to suppose a or x equals to a to b and within that point how this y curve is approximating or how this variation of y is occurring that we tried to estimate with the axis bounding region with this curve there. This means that if y equal to f of x is a function is defined and how this area is occurring or how this aerial interaction or this enclosure is occurring within this x -axis for 2 fixed points that can be evaluated by using integrations here.

So why we are just going for this numerical integration, if the function f of x is not given as I have told you but the values are given at a discrete points then we can just use numerical integration to find this values of the function within a given range. Sometimes if some of this complicated functions if it is given like E to the power minus x square suppose within the range of like 0 to 1 dx . So it is very difficult to carry out and in that case if you will just go for numerical integrations it is very easy to evaluate the integration's.

(Refer Slide Time: 05:29)

Methodology For Numerical Integration

- ❑ Let us suppose that the functional values are known at $x=a$, $x=b$ and $(n-1)$ internal points in (a, b) , namely $x=x_i, i=1(1)n-1$.
- ❑ Let us assume that $a=x_0 < x_1 < x_2 \dots < x_n=b$. These points on the x -axis are called pivotal or nodal points.
- ❑ Thus there are $(n+1)$ nodal points, and n sub-intervals $[x_i, x_{i+1}]$, $i=1(1)n-1$.
- ❑ Evaluation of the integral to approximate the function $f(x)$ by a polynomial and integrate it.

 IT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE

Let us suppose that the functional values are known at x equals to a and x equals to b and suppose a and b is divided into n equals this means that n minus 1 internal points in a, b . Suppose this internal points we are just naming as x_1, x_2 , to x_{n-1} , so if you will just visualize this one in a graphical sense here suppose we will have this points like x equals to x_0 to x equals to x_n suppose then we can just divide this range x equal to x_0 equals to x_1 into suppose n 's of intervals.

So we will have now this minus 1 internal points like x_1 to x_2, x_3 upto x_{n-1} , obviously can just write or sometimes for convenience we are just expressing x_0 equals to a and x_n equals to b . Then we can just define this points are as $a = x_0 < x_1 < x_2 < \dots < x_{n-1} < x_n$ this equals to b . So if we are just

approximating any function with a polynomial approximation within this range suppose x_0 to x_n here then we can just obtain a polynomial within that range.

(Refer Slide Time: 07:09)

Methodology For Numerical Integration

- ❑ Let us suppose that the functional values are known at $x=a$, $x=b$ and $(n-1)$ internal points in (a, b) , namely $x=x_i, i=1(1)n-1$.
- ❑ Let us assume that $a=x_0 < x_1 < x_2 \dots < x_n=b$. These points on the x -axis are called pivotal or nodal points.
- ❑ Thus there are $(n+1)$ nodal points, and n sub-intervals $[x_i, x_{i+1}]$, $i=1(1)n-1$.
- ❑ Evaluation of the integral to approximate the function $f(x)$ by a polynomial and integrate it.

8

Methodology For Numerical Integration

- ❑ Approximating the function by a single polynomial globally over the entire domain $a \leq x \leq b$, it is approximated in piecewise manner.
- ❑ We fit the polynomial $P(x)$ over k sub-intervals passing through the points $(x_i, y_i), i=0(1)k$ and evaluate the integral

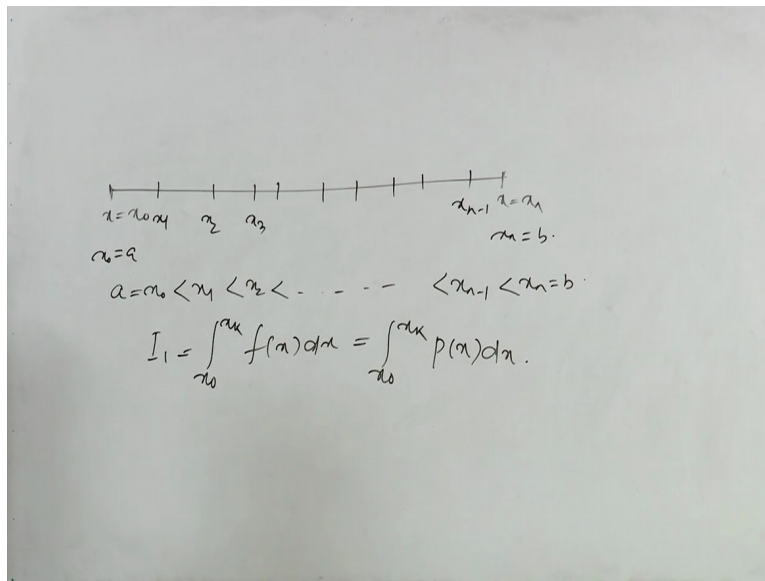

$$I_1 = \int_{x_0}^{x_1} f(x) dx = \int_{x_0}^{x_1} P(x) dx.$$

Obviously it covers k intervals, $(x_i, x_{i+1}), i=0(1)k$. The process is repeated for next k intervals and so on until the entire domain is covered.

9

So in that range we will have $n+1$ nodal points with n 's of intervals like x_i, x_{i+1} , if i is varying from 1 to $n-1$ here. So if you will just approximate this function with a polynomial or we want to fit the polynomial p of x over suppose k 's of intervals here passing through the points like x_i, y_i here, i equals to 0, 1, 2 upto k and evaluate this integrals.

(Refer Slide Time: 07:39)

Methodology For Numerical Integration

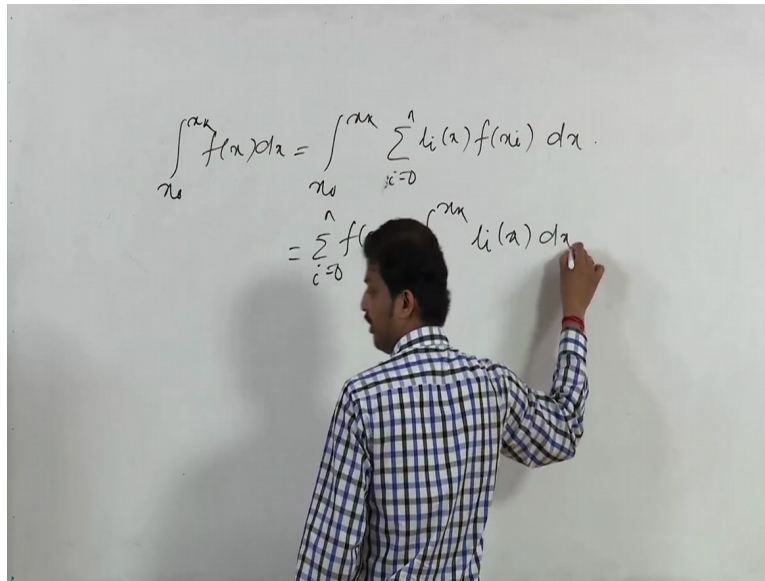

- Approximating the function by a single polynomial globally over the entire domain $a \leq x \leq b$, it is approximated in piecewise manner.
- We fit the polynomial $P(x)$ over k sub-intervals passing through the points $(x_i, y_i), i=0(1)k$ and evaluate the integral

$$I_1 = \int_{x_0}^{x_k} f(x) dx = \int_{x_0}^{x_k} P(x) dx.$$

Obviously it covers k intervals, $(x_i, x_{i+1}), i=0(1)k$. The process is repeated for next k intervals and so on until the entire domain is covered.

So then we can just write $i+1$ as x_0 to x_k , f of x dx or we can just write this one as x_0 to x_k , p of x dx here. Obviously if it covers k intervals like x_i to x_{i+1} for i equals to $0, 1, \dots, k$ here and this process is repeated for all the intervals this means that first it covers k intervals then in the repeated process in the next interval also it can covers like k intervals again, until over the entire domain should be covered off.

(Refer Slide Time: 08:34)

$$\int_{x_0}^{x_k} f(x) dx = \int_{x_0}^{x_k} \sum_{i=0}^n l_i(x) f(x_i) dx$$

$$= \sum_{i=0}^n f(x_i) \int_{x_0}^{x_k} l_i(x) dx$$

Then we will just go for the discussion of this numerical integration in a different interpolation formulas, first will just go for this Lagrange's formula here. So if we will just write this Lagrange's formula, this Lagrange's formula for this polynomial approximation is usually written in the form of summation of like i equals to 0 to n , $l_i x$, f of x_i , where $l_i x$ is called Lagrange's polynomial coefficients.

And usually this $l_i x$ is expressed in the form of like $\omega_i(x)$ divided by $x - x_i$ into $\omega_i'(x_i)$ there. Specifically if we will just write in an elaborated form then we can just write $l_i x$ as $x - x_0, x - x_1$ to $x - x_{i-1}, x - x_{i+1}$ upto $x - x_n$ divided by $x_i - x_0, x_i - x_1$ upto $x_i - x_{i-1}, x_i - x_{i+1}$ upto $x_i - x_n$ here.

If you will just write this integration here this integration can be written as integration of x_0 to x_1 , f of x dx suppose. This can be written as or if we want to write this one as x_0 to x_k suppose in each of these intervals if you will just evaluate x_0 to x_k , f of x into dx this can be written as x_0 to x_k summation of i equals to 0 to n , $l_i x$, f of x_i into dx here or it can be written in the form of summation of i equals to 0 to n , f of x_i integration of x_0 to x_k , $l_i x$ dx here.

(Refer Slide Time: 11:07)

Methodology For Numerical Integration

We will discuss the methods by representing the approximating polynomial in two forms:

1. Lagrange's formula
2. Newton's Forward Difference formula

In the Lagrange's form $P(x) = \sum_{i=0}^k l_i(x) y_i$ so that

$$\int_{x_0}^{x_s} f(x) dx = \int_{x_0}^{x_s} \sum_{i=0}^k l_i(x) y_i dx = \sum_{i=0}^k y_i \int_{x_0}^{x_s} l_i(x) dx$$

$$l_i(x) = \frac{(x-x_0)(x-x_1)\cdots(x-x_{i-1})(x-x_{i+1})\cdots(x-x_k)}{(x_i-x_0)(x_i-x_1)\cdots(x_i-x_{i-1})(x_i-x_{i+1})\cdots(x_i-x_k)}$$

10

Already it is known that $l_i(x)$ can be expressed as the coefficient of x^i here which can be written in the form of either in the form of $\omega_i(x)$ by $x - x_i$ into $\omega_i(x)$ there. So if we will just implement the numerical integration for all this product terms there then we can just evaluate this numerical integration for this polynomial there.

(Refer Slide Time: 11:26)

Methodology For Numerical Integration

When the values of the function $y=f(x)$ are provided at equally spaced abscissas, say $h=x_i-x_{i-1}$, $i=1(1)n$, then the approximating polynomial may be represented by a finite difference formula.

In terms of Newton's FD formula it can be represented as,

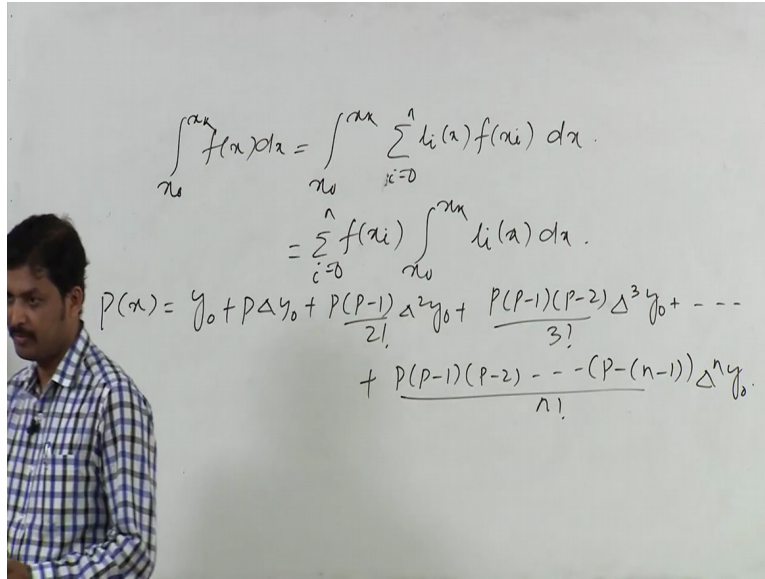

$$P(x) = y_0 + \frac{(x-x_0)}{h} \Delta y_0 + \frac{(x-x_0)(x-x_1)}{2!h^2} \Delta^2 y_0 + \dots$$

$$+ \frac{(x-x_0)(x-x_1)\cdots(x-x_{k-1})}{k!h^k} \Delta^k y_0$$

$$P(p) = y_0 + p\Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \dots + \frac{p(p-1)\cdots(p-k+1)}{k!} \Delta^k y_0$$

where $x=x_0+ph$

11

$$\int_{x_0}^{x_k} f(x) dx = \int_{x_0}^{x_k} \sum_{i=0}^n l_i(x) f(x_i) dx$$

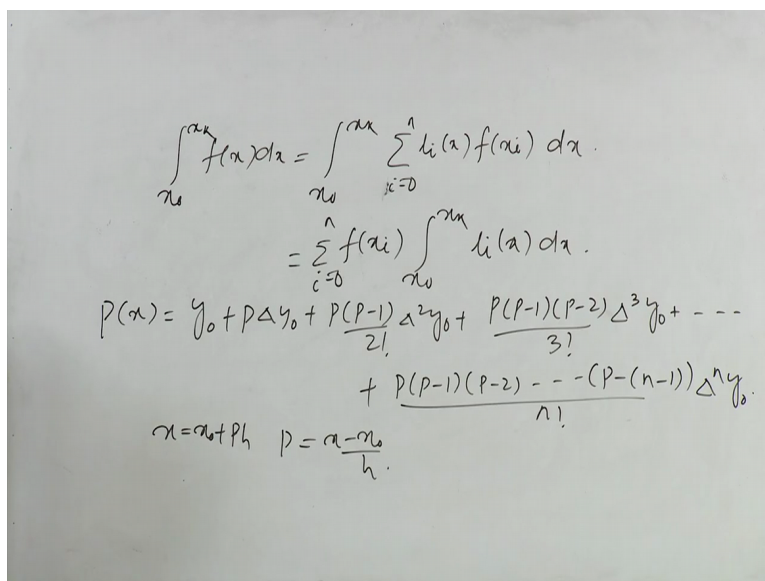

$$= \sum_{i=0}^n f(x_i) \int_{x_0}^{x_k} l_i(x) dx$$

$$p(x) = y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \frac{p(p-1)(p-2)}{3!} \Delta^3 y_0 + \dots$$

$$+ \frac{p(p-1)(p-2) \dots (p-(n-1))}{n!} \Delta^n y_0$$

So next we will just go for this as numerical integration using Newton's forward difference formula, when the values of function y equals to f of x are provided suppose at equally spaced abscissas then we can just use this Newton's forward difference formula. And in finite different approximation usually this Newton's forward difference formula in polynomial form are written as y_0 plus p delta of y_0 , p into p minus 1 by factorial 2, del square of y_0 plus p into p minus 1, p minus 2 divided by 3 factorial, delta cube of y_0 plus upto finite number of terms that is as p into p minus 1, p minus 2 upto p minus n minus 1 divided by n factorial, nablato the sorry delta to the power n of y_0 here plus the remainder term.

(Refer Slide Time: 12:36)

$$\int_{x_0}^{x_k} f(x) dx = \int_{x_0}^{x_k} \sum_{i=0}^n l_i(x) f(x_i) dx$$

$$= \sum_{i=0}^n f(x_i) \int_{x_0}^{x_k} l_i(x) dx$$

$$p(x) = y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \frac{p(p-1)(p-2)}{3!} \Delta^3 y_0 + \dots$$

$$+ \frac{p(p-1)(p-2) \dots (p-(n-1))}{n!} \Delta^n y_0$$

$$x = x_0 + ph \quad p = \frac{x - x_0}{h}$$

Methodology For Numerical Integration

When the values of the function $y=f(x)$ are provided at equally spaced abscissas, say $h=x_i-x_{i-1}$, $i=1(1)n$, then the approximating polynomial may be represented by a finite difference formula.

In terms of Newton's FD formula it can be represented as,

$$P(x) = y_0 + \frac{(x-x_0)}{h} \Delta y_0 + \frac{(x-x_0)(x-x_1)}{2!h^2} \Delta^2 y_0 + \dots$$

$$+ \frac{(x-x_0)(x-x_1)\dots(x-x_{k-1})}{k!h^k} \Delta^k y_0$$

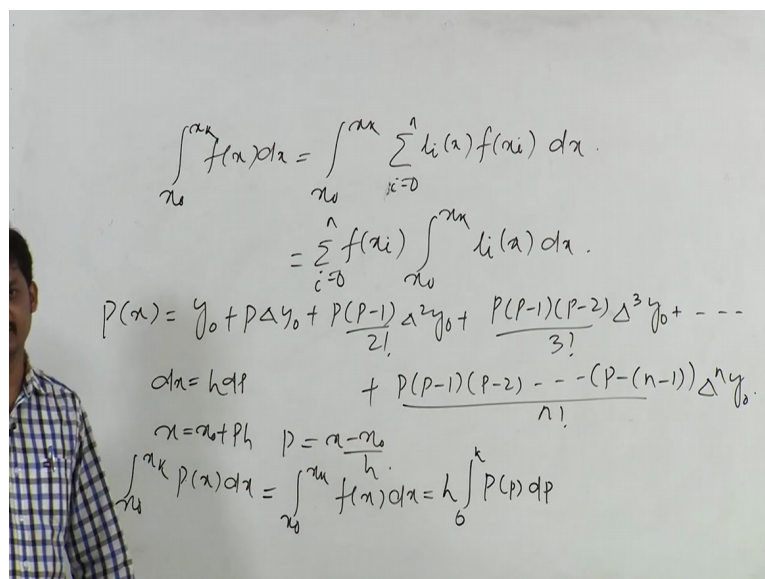

$$P(p) = y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \dots + \frac{p(p-1)\dots(p-k+1)}{k!} \Delta^k y_0$$

where $x=x_0+ph$

So if you will just replace in terms of x here usually we are just replacing here x equal to x_0 plus p h here. So that is why p can be written as $x - x_0$ by h here. And if you will just replace this p value in terms of x here then p of x can be written as y_0 plus $x - x_0$ by h into delta of y_0 then $x - x_0$ into $x - x_1$ by 2 factorial, h square, del square of y_0 plus all other terms in the same fashion.

So we will just write this polynomial in terms of p usually we can just denotes that one in terms of p here that is p of p can be written as y_0 plus p delta of y_0 , p into p minus 1 by 2 factorial, del square of y_0 upto p into p minus 1 upto p minus k plus 1 by k factorial, del to the power k of y_0 there.

(Refer Slide Time: 13:41)

$$\int_{x_0}^{x_k} f(x) dx = \int_{x_0}^{x_k} \sum_{i=0}^n L_i(x) f(x_i) dx$$

$$= \sum_{i=0}^n f(x_i) \int_{x_0}^{x_k} L_i(x) dx$$

$$P(x) = y_0 + p \Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \frac{p(p-1)(p-2)}{3!} \Delta^3 y_0 + \dots$$

$$+ \frac{p(p-1)(p-2)\dots(p-(n-1))}{n!} \Delta^n y_0$$

$dx = h dp$

$x = x_0 + ph \quad p = \frac{x - x_0}{h}$

$$\int_{x_0}^{x_k} P(x) dx = \int_{x_0}^{x_k} f(x) dx = h \int_0^k P(p) dp$$

So if you will just use this integration for this formula here then we can just write integration of x_0 to x_k , p of x dx here or it can be written as x_0 to x_k , f of x dx . This equals to we can just write h into integration of like 0 to since x_0 to x_k here, 0 to k we can just write and p of p into dp here.

Since if you will just see here dx is nothing but $h dp$ if you will just write this one, so that is why this h is coming out and at this point x equals to x_0 , if i will just put p equals to 0 and if i will just put x equals to like x_k that is nothing but x_0 plus $k h$, so that is why p equals to k there. So that is why we are just changing this intervals that is in this form here.

(Refer Slide Time: 14:46)

Methodology For Numerical Integration

Using $P(x)$ or $P(p)$ the integral may be approximated as,

$$\int_{x_0}^{x_k} f(x) dx = \int_{x_0}^{x_k} P(x) dx = h \int_0^k P(p) dp, \quad \because dx = h dp.$$

The error in the above approximation may be obtained by integrating $R(x)$, with respect to x from x_0 to x_k , i.e.,

$$\begin{aligned} E &= \int_{x_0}^{x_k} R(x) dx = \int_{x_0}^{x_k} (x-x_0)(x-x_1)\cdots(x-x_k) \frac{f^{(k+1)}(\xi)}{(k+1)!} dx, \quad x_0 \leq \xi \leq x_k \\ &= \frac{f^{(k+1)}(\xi)}{(k+1)!} \int_{x_0}^{x_k} (x-x_0)(x-x_1)\cdots(x-x_k) dx \\ &= \frac{h^{k+2} f^{(k+1)}(\xi)}{(k+1)!} \int_0^k p(p-1)\cdots(p-k+1) dp \end{aligned}$$

NPTEL ONLINE CERTIFICATION COURSE
12

$$\begin{aligned} R(x) &= \frac{P(P-1)(P-2) \cdots (P-k)}{(k+1)!} \Delta^{k+1} y_0 \\ &= \frac{(x-x_0)(x-x_1) \cdots (x-x_k)}{(k+1)!} f^{(k+1)}(\xi) \end{aligned}$$

So in this regard also we can just write this error term also, so usually this error terms are usually written in the form of like x minus x_0 . So for this Newton's divided difference formula if you will just write this error term that can be written as, so this error term this Newton's interpolation formula R of x can be written as p into p minus 1 into p minus 2 upto p minus k if you will just write to k -th term here.

So we can just write in this form or divided by you can just write k factorial here and del to the power sorry this is k plus 1 factorial here and del to the power k plus 1 y_0 here. And in terms of x if you will just write this can be written in the form of like x minus x_0 , x_1 minus x_1 upto x minus x_k divided by k plus 1 factorial and it can be written also h term it is also there, so that is why we can just write this one as f to the power k plus 1 η divided by k plus 1 factorial here.

(Refer Slide Time: 16:27)

Methodology For Numerical Integration

Using $P(x)$ or $P(p)$ the integral may be approximated as,

$$\int_{x_0}^{x_k} f(x) dx = \int_{x_0}^{x_k} P(x) dx = h \int_0^k P(p) dp, \quad \because dx = h dp.$$

The error in the above approximation may be obtained by integrating $R(x)$, with respect to x from x_0 to x_k , i.e.,

$$\begin{aligned} E &= \int_{x_0}^{x_k} R(x) dx = \int_{x_0}^{x_k} (x-x_0)(x-x_1)\cdots(x-x_k) \frac{f^{(k+1)}(\xi)}{(k+1)!} dx, \quad x_0 \leq \xi \leq x_k \\ &= \frac{f^{(k+1)}(\xi)}{(k+1)!} \int_{x_0}^{x_k} (x-x_0)(x-x_1)\cdots(x-x_k) dx \\ &= \frac{h^{k+2} f^{(k+1)}(\xi)}{(k+1)!} \int_0^k p(p-1)\cdots(p-k+1) dp \end{aligned}$$

If you just integration this one within this range of x_0 to x_k here, so this can be written as x_0 to x_k , R of x dx this can be written as x_0 to x_k here like x minus x_0 to x minus x_k here divided by k plus 1 factorial, f to the power k plus 1 ξ here, where ξ should be lies between x_0 to x_k here. So if we will just take out this term like f of the power k plus 1 ξ by k plus 1 factorial as that are constant so it can be taken out, so inside this integrations we can just write x_0 to x_k , x minus x_0 , x minus x_1 to x minus x_k into dx here.

(Refer Slide Time: 017:36)

So if you will just eliminate the dx as in the form of $h dp$ here, so then x minus x_0 and x minus x_1 in terms of p here, so we can just write that the total term can be written as h to the power k plus 2 , this can be written as a h to the power k plus 2 divided by k plus 1 factorial, f

to the power $k + 1$ zeta, integration from 0 to k, p into $p - 1, p - 2$ upto $p - k + 1$ here into $d p$. Sorry this should be $p - k$ upto that one since $x - k$ is there.

(Refer Slide Time: 18:33)

Methodology For Numerical Integration

The total error (TE) in computing integral $I = \int_{x_0}^{x_k} f(x) dx$ would be sum of the module of the errors, the number of times an integration formula is used to cover the interval (x_0, x_n) .

We shall now discuss some methods, that are based on equally-spaced abscissas. Let us suppose that the interval (a, b) is subdivided into n sub-intervals, each of width h , such that, $h = (b - a)/n$; $x_i - x_{i-1} = h$, $i = 1(1)n$, and also, $a = x_0 < x_1 < x_2 \dots < x_n = b$.

NPTEL ONLINE CERTIFICATION COURSE
13

So this is the integration formula, so if you just go for this like total error in computing the integral i equals to x_0 to x_k , f of x into dx , then sum of the model of errors that is the number of times it is just occurring in each of intervals that can be taken off and sum of all this terms to cover off this error terms in each of this intervals x_0 to x_n . So now we shall discuss some of the methods that are based on equally spaced abscissas, suppose that interval a, b is subdivided suppose n 's of intervals here each of width suppose h here then we can just define h equals to b minus a by n here.

(Refer Slide Time: 19:17)

So suppose in a graphical sense if you just visualize we can just define x_0 to x_n upto x_n equals to b here, so then we can just define if all this points are equally spaced here then we can just define h equals to b minus a by n or we can just write x_n minus x_0 by n here. And each of this points since it is equi-spaced here we can just write x_i equals to x_{i-1} plus h here, where i is varying from like 1 to n here incremented by 1.

(Refer Slide Time: 20:22)

Rectangular Rule

- ❑ In the rectangular rule (or method), the function $f(x)$ is approximated by a constant value of $f(x)$ at $x=x_0$, i.e. $y_0=f(x_0)$ in the first interval (x_0, x_1) .
- ❑ In the second interval it is approximated by $y_1=f(x_1)$ and so on until in the last n interval (x_{n-1}, x_n) it is approximated by $y_{n-1}=f(x_{n-1})$.

 IIT KHARAGPUR

 NPTEL ONLINE
CERTIFICATION COURSE

14

So and we can just define this points that is in the form of like a equals to x_0 less than x_1 upto less than x_n equals to b here. And if you just go for this rectangular rule suppose, in the rectangular rule form usually this method is applicable whenever we have a constant value of

function which attains its maximum value within that range. This means that if suppose we will have a integration range from x_0 to x_1 then we can just assume that y_0 or this functional values at x_0 can be considered as a constant value for f of x within the whole interval there.

(Refer Slide Time: 21:00)

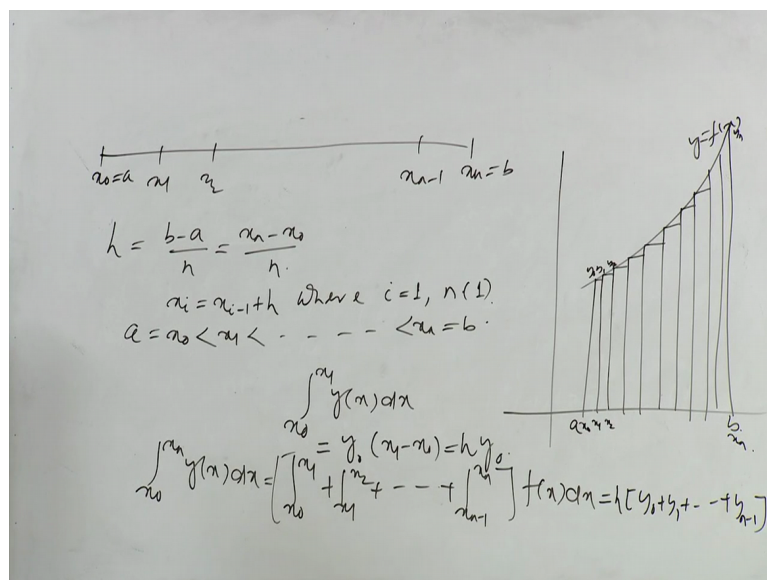

And in the 2nd interval the same fashion we can just approximate that one y_1 as f of x throughout the interval and in that case we can just write this integration as in the form of like a real cross-section and within that if you will just divide each of this intervals in a rectangular sections like if suppose we will have this integration range y equals to f of x is given to us and it is asked to evaluate this integration within this range a to b suppose we can just subdivide this total regions into n 's of intervals here. And if you will just take this small

section as a straight line or this perpendiculars we can just draw off at each of this points here since sufficient close intervals we are just considering, so that is why the error of approximation should be minimized in this sense here.

If you will just consider the starting point as x_0 , next point is x_1 and next point is x_2 , likewise the last point is x_n here and corresponding y values like y_0, y_1, y_2 likewise the last point will be y_n here, then we can just consider this integration within this range like x_0 to x_1 , y_1 of x dx or f of x dx which can take the maximum value y_0 within this range x_0 to x_1 here. Then we can just write this integration as y_0 into x_1 minus x_0 here and this can be written as h, y_0 here.

(Refer Slide Time: 023:00)

So similarly we can just define this integration range like x_1 to x_2 , x_2 to x_3 in the same fashion and adding of if you just add up all this areas like x_0 to x_n suppose y of x dx or f of x dx this can be written in the form of like x_0 to x_1 , x_1 to x_2 upto x_{n-1} to x_n , f of x dx here. Then each of this intervals just first interval we can just obtain h of y_0 , 2nd we can just obtain h of y_1 and the 3rd one we can just obtain that one h of y_2 . So likewise if you will just sum of all this terms here then the final integration we can just get it as h into y_0, y_1 , upto y_{n-1} here.

(Refer Slide Time: 23:55)

Rectangular Rule

Adding up such areas over the n intervals, we get

$$\int_{x_0}^{x_n} f(x) dx = \left(\int_{x_0}^{x_1} + \int_{x_1}^{x_2} + \dots + \int_{x_{n-1}}^{x_n} \right) f(x) dx = h(y_0 + y_1 + \dots + y_{n-1})$$

This is known as composite formula for n intervals.

□ If the function is monotonically increasing then

$$\int_a^b f(x) dx > h(y_0 + y_1 + \dots + y_{n-1})$$

□ If the function is monotonically decreasing then

$$\int_a^b f(x) dx < h(y_0 + y_1 + \dots + y_{n-1})$$

16

And if the function is suppose monotonically increasing then we can just write integration a to b, $\int_a^b f(x) dx$ is greater than $h(y_0 + y_1 + \dots + y_{n-1})$. If suppose it is monotonically decreasing then we can just define as integration a to b, $\int_a^b f(x) dx$ is less than $h(y_0 + y_1 + \dots + y_{n-1})$. So then we will just go for like rectangular rule used for Lagrange's formula.

(Refer Slide Time: 24:26)

Rectangular Rule

Approximating function $f(x)$ by $P(x)$ over the interval (x_0, x_1) gives

$$\int_{x_0}^{x_1} f(x) dx = \int_{x_0}^{x_1} P(x) dx = \int_{x_0}^{x_1} y_0 dx = hy_0$$

This formula is the rectangular rule.

The error terms in this formula is given by integration of $R(x)$ between x_0 and x_1 , i.e.,

$$E = \int_{x_0}^{x_1} R(x) dx = \int_{x_0}^{x_0+h} (x - x_0) f'(\xi) dx = \frac{h^2}{2} f'(\xi), x_0 \leq \xi \leq x_1.$$

The composite formula may be written as

$$I = \int_a^b f(x) dx = \int_{x_0}^{x_n} f(x) dx = h(y_0 + y_1 + y_2 + \dots + y_{n-1}).$$

18

$$\begin{aligned}
 & (x_0, y_0) \text{ and } (x_1, y_0) \\
 & p(x) = \frac{x-x_1}{x_0-x_1} y_0 + \frac{x-x_0}{x_1-x_0} y_0 = y_0 \\
 & R(x) = (x-x_0)f'(\xi), \quad x_0 \leq \xi \leq x_1
 \end{aligned}$$

So in the Lagrange's formula suppose if the interval is given like x_0 to x_1 and it is asked to fit with a polynomial passing through the points like x_0, y_0 and x_1, y_0 suppose since the functional values are same at both this points. So then we can just define this polynomial as we will have this points like x_0, y_0 and x_1, y_0 here, this functions values will remain constant at both this points.

Then we can just define this Lagrange's polynomial as x minus x_1 divided by x_0 minus x_1 , y_0 plus x minus x_0 divided by x_1 minus x_0 , y_0 here, so then this total polynomial can be written as y_0 here. And if you will just approximate this error for this polynomial then this error term R of x can be written in the form of like x minus x_0 , f' of ξ , where ξ should be lies between x_0 to x_1 here.

And if you will just integrate this linear interpolating polynomial for Lagrange's method then we can just write this one as x_0 to x_1 , p of x dx , this can be written as y_0 into x_1 minus x_0 that is nothing but h of y_0 here. And this formula is the rectangular rule especially it is called and if you will just approximate the error terms also, this error terms can also be written as E equals to x_0 to x_1 , R of x into dx here.

And that can be written as x_0 to $x_0 + h$, x minus x_0 , f' dash of ξ into dx here, which can be written as h^2 by 2 , f' dash of ξ , where ξ should be lies between x_0 to x_1 . And in the same form we can just obtain this composite formula for this linear interpolating polynomial in Lagrange's method as a to b , f of x dx that as x_0 to x_n , f of x dx , this equals to h into y_0 plus y_1 plus y_2 upto y_{n-1} here.

Methodology For Numerical Integration

Based on Newton's forward formula:

Approximating $f(x)$ in (x_0, x_1) by the first term of Newton's forward interpolating polynomial, then

$$\int_{x_0}^{x_1} f(x) dx = \int_{x_0}^{x_1} P(x) dx = h \int_0^1 P(p) dp = h \int_0^1 y_0 dp = h y_0.$$

The error in the formula is obtained by integrating the next term

$$E = h \int_0^1 p \Delta y_0 dp = \frac{h}{2} \Delta y_0 = \frac{h^2}{2} f'(\xi), \quad \because \frac{\Delta y_0}{h} = f'(\xi).$$

19

So based on Newton's forward formula if you will just go for this calculation is here like if we will have this function f of x in x_0 to x_1 by terms of Newton's forward interpolating polynomial here, usually we can just write x_0 to x_1 , f of x dx here or that can be written in the form of x_0 to x_1 , p of p into dx here. And obviously this integration range for the p of p can be transformed to 0 to 1 and dx can be written as $h dp$ here.

So that is why we can just write this one as h , 0 to 1 into your functional value y_0 into dp here and this specially can be written as $h y_0$. And in a similar fashion also we can just determine the error for this formula that can be written as E equals to h , 0 to 1, p delta of y_0 into dp , so which can be written as h^2 by 2, f' dash of ξ .

Since we have known that $\frac{\Delta y}{h}$ is equal to $f'(z)$, so in both this method we are obtaining this same formula for rectangular rule. Thank you for listening this lecture on numerical integration, next lecture we can just continue for this numerical integration based on Newton's forward difference formula and all other interpolation formulas.
