Lecture - 13
Eigen values & Eigenvectors- I

Hello friends, I welcome you to my lecture on Eigen values and Eigen vectors. There will be two lectures on this topic. This is our first lecture. Now, Eigen values have their greater significance in dynamic problems, the solution of the equation $\frac{du}{dt} = Au$.

(Refer Slide Time: 00:37)

Eigen Values and Eigen Vectors

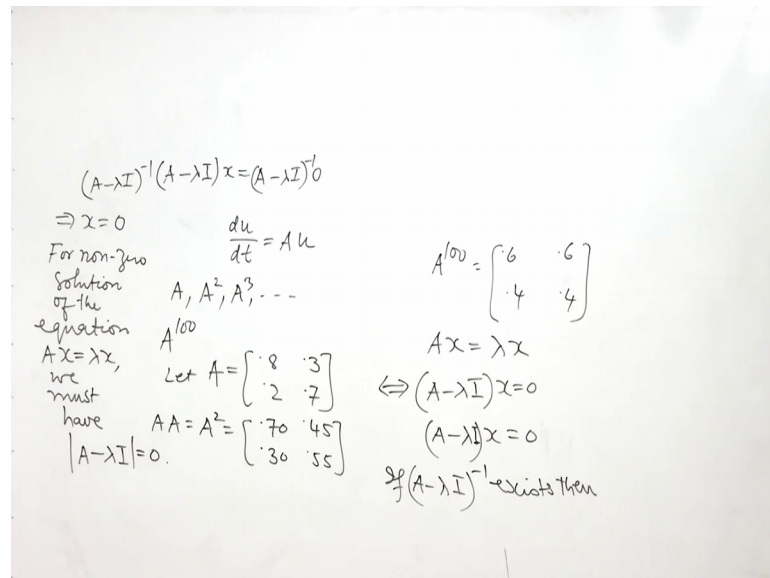

Eigen values have their greatest significance in dynamic problems. The solution of $\frac{du}{dt} = Au$ is changing with time – growing or decaying or oscillating.

A good example of how the concept of eigen values is important comes from the powers of A, A^2, A^3, \dots of a square matrix. Suppose we want the hundredth power A^{100} of A then the starting matrix A becomes unrecognizable after a few steps and A^{100} is very close to $\begin{bmatrix} .6 & .6 \\ .4 & .4 \end{bmatrix}$:

$$\begin{matrix} \begin{bmatrix} .8 & .3 \\ .2 & .7 \end{bmatrix} & \begin{bmatrix} .70 & .45 \\ .30 & .55 \end{bmatrix} & \begin{bmatrix} .650 & .525 \\ .350 & .475 \end{bmatrix} & \dots & \begin{bmatrix} .6000 & .6000 \\ .4000 & .4000 \end{bmatrix} \\ A & A^2 & A^3 & & A^{100} \end{matrix}$$

ITR ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

(Refer Slide Time: 00:40)

Where A is a matrix and u is a vector, changing with time. With time growing, decaying or oscillating are good examples. The concept of Eigen values comes from powers of A, A square a cube and so on. Suppose, we want 100 power of A. Then let us take the matrix A to B. Let the matrix AB be equal to 0.8, 0.3, 0.2, 0.7. Then, we can calculate A square, A cube up to a certain stage after that, it becomes very difficult to calculate the powers of A. So, if you calculate A square, A square comes out be 0.70, 0.45, 0.30 and 0.55.

So, A into A which is A square. We can calculate by matrix multiplication. We can multiply A square by A again, get A cube. 0.650, 0.525, 0.3, 0.0, 0.475 but after a few steps, the matrix will become unrecognisable and we will see that, by using the concept of Eigen values and Eigen vectors, we can calculate A 100 and it is very close to 0.6, 0.4, 0.66 and 0.44. So, we shall see how we can calculate A to the power 100. This A to the power 100 is not calculated by the matrix multiplication, which is by multiplying the matrix 100 times. We will be calculating it by using Eigen values and Eigen vectors, to explain the Eigen values, first, let us explain Eigen vectors. Almost all vectors change the direction.

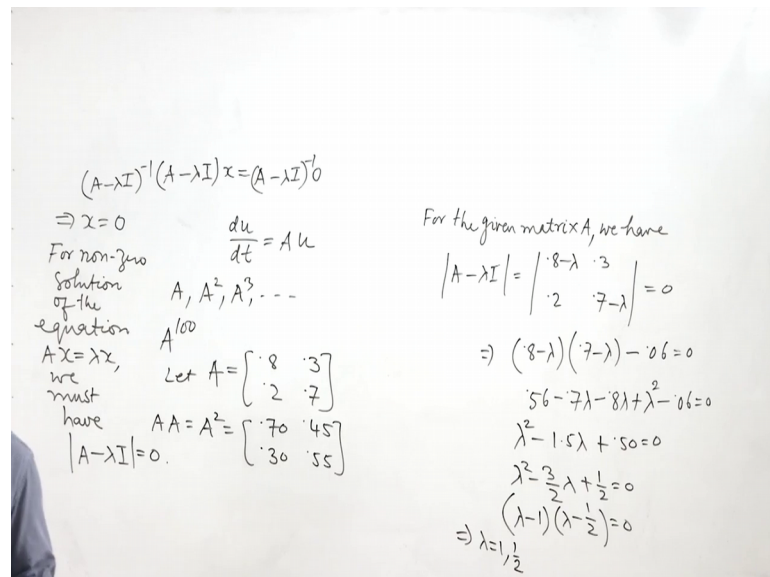

But when they are multiplied by the matrix A, there are certain exceptional vectors, which keep the same direction, when they are multiplied by x. So, those vectors are called the Eigen vectors. Thus, the vector Ax, the vector x 1 multiplied by A, is elder

number λ times the original vector x . So, the basic equation is $Ax = \lambda x$, let us again repeat, we have the vector x , when we multiply it by A , we get a number λ times the original vector x . So, certain exceptional vector satisfies this kind of thing. So, such a vector is called Eigen vector and λ is called its Eigen value. So, we can also write this equation as $(A - \lambda I)x = 0$. Remember, we cannot write it as $(A - \lambda)x = 0$. This is not right because, A is a matrix and λ is a scalar quantity, we cannot subtract the λ from A .

So, we should multiply this by identity matrix of the same order as A . So, the correct way of writing $Ax = \lambda x$ is, $(A - \lambda I)x = 0$. So, this is the alternate form of $Ax = \lambda x$. Now, suppose so happens that the matrix $A - \lambda I$ is invertible, then, we can see from here if $A - \lambda I$ is invertible, that is $(A - \lambda I)^{-1}$ exists then, multiply this equation by $(A - \lambda I)^{-1}$, what we will get is $(A - \lambda I)^{-1}(A - \lambda I)x = (A - \lambda I)^{-1} \cdot 0$. So, $(A - \lambda I)^{-1}(A - \lambda I)$ is identity matrix. Identity matrix into x is x . So, this gives us $x = 0$ and $(A - \lambda I)^{-1} \cdot 0$, will give 0 . So, $x = 0$.

So, when $(A - \lambda I)^{-1}$ exists, what we get is $x = 0$ and we can see from here that $x = 0$ clearly satisfies this equation. So, we are interested in those vectors x which are nonzero vectors and satisfy the equation $Ax = \lambda x$. So, where we want the vector to be a nonzero vector, for the nonzero vector $(A - \lambda I)^{-1}$ must not exist, that is, determinant of $(A - \lambda I)$ is equal to 0 . So, for nonzero solution of the equation $Ax = \lambda x$, we must have determinant of $(A - \lambda I)$ equal to 0 , because we know that if determinant of $(A - \lambda I)$ is nonzero, then $(A - \lambda I)^{-1}$ exists.

(Refer Slide Time: 06:52)

So, now let us find determinant of A minus lambda I for the given matrix A. For the given matrix A, we have determinant of A minus lambda I equal to determinant of A minus lambda I. The matrix A minus lambda I is the matrix where, the diagonal elements of A are subtracted by lambda. So, we shall have 0.8 minus lambda 0.3 and then 0.2, 0.7 minus lambda. So, let us put this equal to 0. So, this will give us 0.8 minus lambda into 0.7 minus lambda minus 0.06 equal to 0.03 into 0.2, determinant of this is AB CD AD minus BC and when we solve this is 0.56 minus 0.7 lambda minus 0.8 lambda plus lambda square minus 0.06 equal to 0.

So, I can write it as lambda square. This is minus 1, 0.5 lambda and here we get 0.50. So, this is lambda minus square minus 3 by 2 lambdas plus 1 by 2 equal to 0. I can write it as lambda minus 1 factors are, lambda minus 1 into lambda minus half equal to 0. So, the Eigen values are lambda equal to 1 and half we get two values of lambda 1 and half for which determinant of A minus lambda I is equal to 0. Now, we shall calculate the Eigen vector for each of these two Eigen values. So, let us first calculate the Eigen vector for lambda I equal to 0.

(Refer Slide Time: 09:10)

So $|A-\lambda I| = 0 \Rightarrow \lambda = 1, \frac{1}{2}$.

Eigen vector for $\lambda=1$:

$$(A-I)x = 0 \Rightarrow \begin{bmatrix} -2 & 3 \\ 2 & -3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\Rightarrow 2x_1 = 3x_2 \quad \text{or} \quad x_1 = \frac{3}{2}x_2.$$

If $x_2 = 4$ then $x_1 = 6$ hence *eigenvector* = $\begin{bmatrix} 6 \\ 4 \end{bmatrix}$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

(Refer Slide Time: 09:15)

Eigen vector for $\lambda = \frac{1}{2}$: $(A - \frac{1}{2}I)x = 0$
 $\Rightarrow \begin{bmatrix} 3 & 3 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$

Eigen vector for $\lambda = 1$:
 $(A - I)x = 0$
 here $\lambda = 1$, we get
 $(A - I)x = 0$
 $\begin{bmatrix} -2 & 3 \\ 2 & -3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$
 $2x_1 = 3x_2$
 $x_1 = \frac{3}{2}x_2$

Let $x_2 = 4$
 then $x_1 = 6$
 So eigenvector is $\begin{bmatrix} 6 \\ 4 \end{bmatrix}$

The eigen vector for $\lambda = \frac{1}{2}$ is $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$
 For the eigen value $\lambda = 1$
 we have $Ax = x$
 For the eigen value $\lambda = \frac{1}{2}$
 we have $Ax = \frac{1}{2}x$

$Ax = \frac{1}{2}x$
 $\lambda = \frac{1}{2}$ then $x = \begin{bmatrix} 6 \\ 4 \end{bmatrix}$
 $Ax = \frac{1}{2}x$
 $\lambda = 1$ then $x = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$

So, the equation from which we will determine the Eigen vector x is A minus λI x equal to 0. So, let us put here λ is equal to 1. So, we get A minus I into x equal to 0. A minus I , means subtract the unit matrix from the matrix A . So, A minus I becomes 0.7, 0.3 and 0.2 and 8 minus 0.28 minus λ is equal to 11 minus 0.8 is 0.0 minus 0.23, then 0.27 minus 1 is minus 0.3, and let us say the vector x has components x_1, x_2 . 0 is the 0 vector. So then, we will have these two equations minus 0.2 x_1 plus 3 x_2 . 3 x_2 equal to 0 and then 0.2 x_1 minus 0.3 x_2 equal to 0, they are both same equations.

So, what we get is $0.2x_1 = 0.3x_2$ or we can say, x_1 is equal to $1.5x_2$. So, if I take x_2 equal to 0.4 . Let us say, I take x_2 equal to 0.4 then x_1 is equal to 0.6 , and so, Eigen vector maybe taken as $0.6, 0.4$. So, there is an Eigen vector corresponding to $\lambda = 1$. Similarly, eigenvector for $\lambda = 0.5$. So here, in this equation, let us put $\lambda = 0.5$, then we shall have $A - 0.5I$ equal to 0 . So, we subtract half I from the matrix A . So, this will give you 0.5 minus 0.8 . So, 0.3 and then 0.2 and then 0.2 , x is again a, let us say x_1, x_2 .

So, we get $0.3x_1 + 0.3x_2 = 0$. Net equation is $0.2x_1 + 0.2x_2 = 0$. So, we can say $x_1 = -x_2$ or $x_1 = -x_2$. So, taking $x_2 = -1$, we will get $x_1 = 1$. So, let x_2 be minus 1 , and then x_1 is equal to 1 . So, we have Eigen vectors as $1, -1$. So, we got the Eigen vector forwarding vectors for both the Eigen values. So, the Eigen vector for $\lambda = 0.5$ is 1 and -1 for the Eigen value $\lambda = 1$. We notice that we have $Ax = \lambda x$, again the Eigen vector x after we multiplied by A remains the same, it does not change, and for the Eigen value $\lambda = 0.5$, what we have? We have $Ax = 0.5x$.

So, suppose we have this vector for $\lambda = 1$, this vector is x and $Ax = x$. So, $Ax = x$, after we operate by A , it remains the same. Now, in the case this is for $\lambda = 1$, for $\lambda = 0.5$, let us say this is the vector, this is the Eigen vector. Here, x is equal to your $0.6, 0.4$ for the case $\lambda = 1$ x is equal $0.6, 0.4$. So, let us say this represents x , when you operate on it by A , what you get is, this same vector, but here, suppose this is your vector x in the case $\lambda = 0.5$.

So, x let us say, this one $1, -1$. So, this is $1, -1$ vector, when we operate by A it becomes half. So, let us say, this is $0.5x$. So, this is $Ax = 0.5x$. So, if we keep the same direction, but its magnitude becomes half of that. So, length becomes half. So, this is how we see that in the case of $\lambda = 1$, director does not change, it remains the same. When we take $\lambda = 0.5$, it shrinks. So, the Eigen value λ tells whether the vector x is stretched, for example, if you take $\lambda = 2$, the Eigen vector Ax will become $2x$.

(Refer Slide Time: 15:45)

Here A^{100} is found by using the eigen values of A and not by multiplying 100 matrices.

To explain the eigen values, first we explain eigen vectors. Almost all vectors change direction, when they are multiplied by the matrix A.

Certain exceptional vectors x are in the same direction as Ax. Those are the eigen vectors. Thus, the vector Ax is a number λ times the original vector x. The basic equation is $Ax = \lambda x$. The number λ is an eigen value of A.

The eigen value λ tells whether the vector x is stretched ($\lambda = 2$) or shrunk ($\lambda = 1/2$) or reversed ($\lambda = -1$) or left unchanged ($\lambda = 1$), when it is multiplied by A.

$$Ax = \lambda x \Leftrightarrow (A - \lambda I)x = 0. \quad \text{---(1)}$$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 3

So, it will stretch Eigen vector I, vector x will stretch and if we take lambda equal to half, we will have Ax equal to half x. So, Eigen vector will shrink and if we take lambda equal to minus 1, then Ax will become equal to minus x. So, it will be reverse and if we take lambda I equal to 1, it will remain unchanged. So, how we interpret the positive and negative values of lambda and the value which are more than 1 are the value which are less than 1. So, now let us see how we found A 100 by the use of Eigen values, Eigen vectors.

(Refer Slide Time: 16:42)

our matrix

$$A = \begin{bmatrix} 8 & 3 \\ 2 & 7 \end{bmatrix}$$

When we multiply the matrix A by A to get A^2 , what we do?

We write

$$A^2 = A A = \begin{bmatrix} 8 & 3 \\ 2 & 7 \end{bmatrix} \begin{bmatrix} 8 & 3 \\ 2 & 7 \end{bmatrix}$$

Let us take the first column of the matrix

$$\begin{bmatrix} 8 \\ 2 \end{bmatrix} = \begin{bmatrix} 6 \\ 4 \end{bmatrix} + 2 \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

then

$$A \begin{bmatrix} 8 \\ 2 \end{bmatrix} = A \begin{bmatrix} 6 \\ 4 \end{bmatrix} + 2 A \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

1st column of $A^2 = \begin{bmatrix} 6 \\ 4 \end{bmatrix} + 2 \frac{1}{2} \begin{bmatrix} 1 \\ -1 \end{bmatrix}$

1st column of $A^2 = A \begin{bmatrix} 6 \\ 4 \end{bmatrix} + 2 \frac{1}{2} A \begin{bmatrix} 1 \\ -1 \end{bmatrix}$

$$= \begin{bmatrix} 6 \\ 4 \end{bmatrix} + 2 \left(\frac{1}{2}\right)^2 \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

Our matrix A is $\begin{pmatrix} 0.8 & 0.3 \\ 0.2 & 0.7 \end{pmatrix}$. Its first column is $\begin{pmatrix} 0.8 \\ 0.2 \end{pmatrix}$ for λ equal to 1, the Eigen vector is $\begin{pmatrix} 0.6 \\ 0.4 \end{pmatrix}$ and for λ , equal to half the eigenvector is $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$. When you multiply the matrix A by A, what we do is, when we multiply the matrix A by A to get A square. What we do? We write A into A, A square is, A into A, then the matrix is multiplied by the column of, by the columns of the matrix A, that is A matrix. So, $\begin{pmatrix} 0.8 \\ 0.3 \\ 0.2 \\ 0.7 \end{pmatrix}$, we multiply it by the first column of this matrix, $\begin{pmatrix} 0.8 \\ 0.3 \\ 0.2 \\ 0.7 \end{pmatrix}$. We multiply the first column to this matrix, and then when you multiply first column to both - first row and second row, we get the first column of the matrix A square, and then we multiply second column to the rows of the matrix A, we get the second column.

So, what we do is? So let us take the first column of the matrix A and then take the first column. Lets take the first column of the matrix A, which is $\begin{pmatrix} 0.8 \\ 0.2 \end{pmatrix}$ and write it as a linear combination of the Eigen vectors for λ equal to 1 and λ equal to half. So, the Eigen vector for λ equal to 1 is $\begin{pmatrix} 0.6 \\ 0.4 \end{pmatrix}$ and for the Eigen vector for the Eigen value λ equal to half, it is $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$. So, what we will do, we will have to multiply it by half, 0.6, no 0.2 we have to multiply. So, 0.2, so the first column of the matrix which is $\begin{pmatrix} 0.8 \\ 0.2 \end{pmatrix}$ can be written as $0.6 \begin{pmatrix} 0.6 \\ 0.4 \end{pmatrix} + 0.2 \begin{pmatrix} 1 \\ -1 \end{pmatrix}$, then will get this.

Now, what we do is, we pre multiplied this y A. So, then A, when you pre multiplied $\begin{pmatrix} 0.8 \\ 0.2 \end{pmatrix}$ by A, what you get is the first column of A square. First column of A square is obtained when we multiply A matrix by the first column of the matrix A. So, first column of A square, we are getting. Now here, what happens, this is a Eigen vector corresponding to λ equal to 1. So, Ax equal to X . So, we get $\begin{pmatrix} 0.6 \\ 0.4 \end{pmatrix}$ and here 0.2 times, this Eigen vectors, corresponding to λ I equal to half. So, Ax equal to half x. So, we get a half times then minus 1. So, this is how we get the first column of A square.

Now, the first column of A square which we get, is again multiplied by A and will get the first column of A cube. So, first column of A cube, this first column of A square is pre multiplied by A to get the first column of A cube. So, again A times $\begin{pmatrix} 0.6 \\ 0.4 \end{pmatrix}$ plus 0.2 times half, but A minus 1. Let us again see, this is Eigen vector for λ equal to 1. So, Ax equal to x. So, we get $\begin{pmatrix} 0.6 \\ 0.4 \end{pmatrix}$ and here 0.2 times this Eigen vector for λ I equal to half. So, Ax equal to half x. So, 0.2 then by 2 square.

So, first column of A cube is, when we find what we get is the Eigen vector for λ equal to 1 plus 0.2 times half square then, the Eigen vector for λ equal to half, we

continue this process and then the first column of A^{100} will be equal to continuing this process, first column of A^{100} will be equal to $0.6, 0.4, 0.21$ by 2 raised to the power 99, 1 and minus 1. Now, 1 by 2 raised to the power 99 very small value, it does not show up to the first 30 places.

(Refer Slide Time: 22:58)

Continuing this process
1st column of A^{100}

$$= \begin{bmatrix} .6 \\ .4 \end{bmatrix} + 2 \left(\frac{1}{2}\right)^{99} \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$
 Approx.
 1st column of $A^{100} = \begin{bmatrix} .6 \\ .4 \end{bmatrix}$

2nd column of A^2

$$= A \begin{bmatrix} .3 \\ .7 \end{bmatrix} = \begin{bmatrix} .6 \\ .4 \end{bmatrix} - 3 \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

2nd column of A^{100}

$$= \begin{bmatrix} .6 \\ .4 \end{bmatrix} - 3 \left(\frac{1}{2}\right)^{99} \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

2nd column of A^2

$$= A \begin{bmatrix} .6 \\ .4 \end{bmatrix} - 3 A \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

$$= \begin{bmatrix} .6 \\ .4 \end{bmatrix} - 3 \frac{1}{2} \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

2nd column of $A^3 = A \begin{bmatrix} .6 \\ .4 \end{bmatrix} - 3 \left(\frac{1}{2}\right) A \begin{bmatrix} 1 \\ -1 \end{bmatrix}$

$$= \begin{bmatrix} .6 \\ .4 \end{bmatrix} - 3 \left(\frac{1}{2}\right)^2 \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

2nd column of A^{100}

$$= \begin{bmatrix} .6 \\ .4 \end{bmatrix} - 3 \left(\frac{1}{2}\right)^{99} \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

So, approximately we can say that the first column of A to the power 100 is nothing, but $0.6, 0.4$. So, approximately, first column of $0.6, 0.4$. Similarly, when we want to find the second column of A to the power 100, we note that, the second column of A square is obtained when we multiply the matrix A by the second column of A .

So, second column of A is equal to A into second column of A and second column of A was equal to $0.3, 0.7$. This is second column of A . So, second column of A^1 multiplied to A gives you second column of A square. Now, we will again repeat the same thing, but the second column of A matrix, shall be written as a linear combination of the vectors A corresponding to the Eigen values 1 and half. So, $0.3, 0.7$. Let us write as a linear combination of A , those 2 values of $0.6, 0.4$ and that what I want is 0.3 . So, minus 0.3 , so, minus 0.3 times 1 minus 1. So, I can write $0.3, 0.7$ as $0.6, 0.4$ point minus 0.3 times 1 minus 1, then I pre multiply by A .

So, when we pre multiplied by A . So, second column of A square will be a $0.6, 0.4$ minus $0.3 A$ 1 minus 1. So, this is point $0.6, 0.4$ minus 0.3 into half, 1 minus 1, because this Eigen vector for λ equal half is equal to 1. Similarly, second column of A cube will

be equal to A, let us apply A of matrix on this pre multiply. So, this will be equal to A here, and then 1 minus 1. So, this will be 31 by 2 square, 1 minus 1 and again continuing this process the second column of A 100, this will be equal 0.6, 0.4 minus 0.3, then by 2 raise to the power 99 and then 1 minus 1, again this is a very small value, so it does not show up to the first 30 places.

So, approximately second column is also 0.6, 0.4. So, second column approximately is 0.6, 0.4. So, the matrix A to the power 100, has first column as 0.6, 0.4 and second column is 0.6, 0.4. So, this how, we get the matrix A to the power 100 by using Eigen values and Eigen vectors. So, this is what we have discussed here. Now, the Eigen vector x equal to 0.6, 0.4 is a steady state, because it does not change,

(Refer Slide Time: 28:26)

The eigen vector $x = \begin{bmatrix} .6 \\ .4 \end{bmatrix}$ is a "steady state" that does not change (because the $\lambda_1 = 1$).

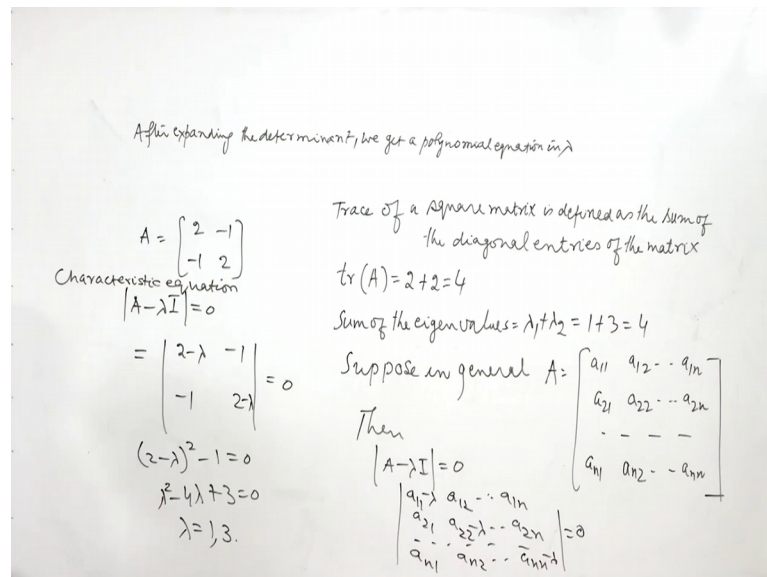

The eigen vector $x = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$ is a "decaying mode" that virtually disappears (because $\lambda_2 = .5$).

The higher the power of A, the closer its columns approach the steady state.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

It remains the same due to the fact that Eigen value is lambda 1 equal to the eigenvector x equal to 1 minus 1, is an decaying mode because it does virtually disappear, because lambda 2 is, half the higher the power of A, the closer its columns approach the steady state in this case.

(Refer Slide Time: 28:57)

So, let us now take away another example. Suppose, we take the matrix A equal to $\begin{bmatrix} 2 & -1 \\ -1 & 2 \end{bmatrix}$. We want to find the Eigen values and Eigen vectors of this matrix. So, what we will do is, we will write the characteristic equation $|A - \lambda I| = 0$ is called the characteristic equation, and its roots are called the Eigen values or characteristic values. So, Eigen values are also called characteristic equation roots. So, here what we will have is $2 - \lambda$ minus $2 - \lambda$ minus $1 \cdot 2$. So, this will give you here, $2 - \lambda$ whole square when we write that, the value of the determinant then we get, minus 1 equal to 0 . So, what we will get is $\lambda^2 - 4\lambda + 3 = 0$. So, the roots of this are λ equal to 1 and 3 . So, the Eigen values of the matrix A are: -1 and 3 . Now, let us note the following sum of the Eigen values, you can see is equal to sum of the diagonal elements.

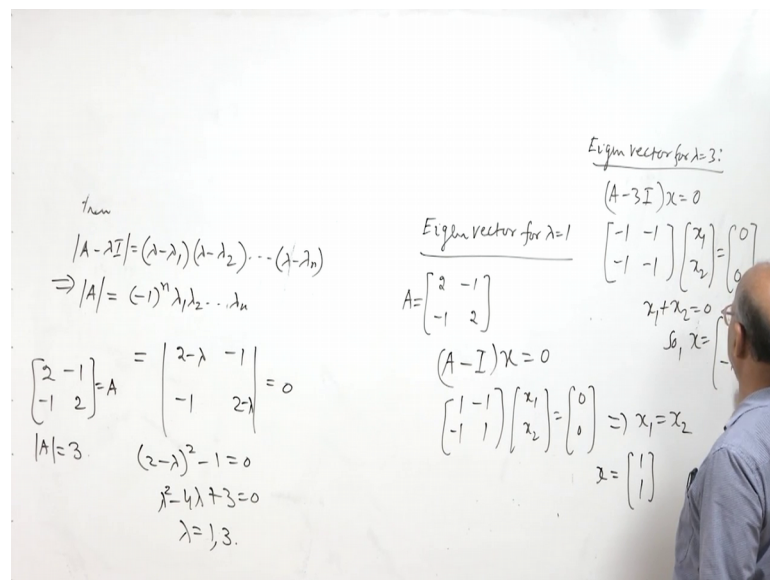

So, it is the property of the Eigen values. So, the trace of a matrix is equal to trace of a square matrix, defined as the sum of the diagonal entries of the matrix. So, here trace of A which we write as $\text{tr}(A)$ is equal to the Eigen diagonal entries, to which is $1 + 3 = 4$. So, 4 and you can see some of the Eigen values, let us say, the sum of the Eigen values is equal to $\lambda_1 + \lambda_2 = 1 + 3 = 4$. So, there is a check on the values of λ that you get you can see, whether the sum of the Eigen values equals the sum the trace of the matrix A or not, that we can easily find trace of the matrix.

So, suppose in general here, the matrix is 2 by 2 . Suppose in general, the matrix is n by n . Suppose in general, A is the matrix. So, A by $a_{11}, a_{12}, a_{21}, a_{22}, \dots, a_{n1}, a_{n2}, \dots, a_{nn}$ and then a

$a_{11}, a_{12}, \dots, a_{1n};$ then determinant of $A - \lambda I$ equal to 0 will give you $a_{11} - \lambda, a_{12} - \lambda$ and so on. a_{21} and $a_{22}, a_{21} - \lambda, a_{22} - \lambda$ and so on. $a_{n1}, a_{n2}, \dots, a_{nn} - \lambda$ equal to 0, when we solve this, it will give you a polynomial equation in λ of degree n .

So, the polynomial in λ is called the characteristic polynomial. So, what we get expanding the determinant is, we get a polynomial equation in λ . So suppose, this will be a polynomial equation λ of degree n . So, it will have in general n roots.

(Refer Slide Time: 34:08)

Let the roots of the equation be $\lambda_1, \lambda_2, \dots, \lambda_n$, then determinant $A - \lambda I$, we can write equal to $(\lambda - \lambda_1)(\lambda - \lambda_2) \dots (\lambda - \lambda_n)$ and so on. $\lambda - \lambda_1, \lambda - \lambda_2, \dots, \lambda - \lambda_n$, suppose roots are $\lambda_1, \lambda_2, \dots, \lambda_n$, we can notice of one more property form here, taking λ equal to 0. You can see that the determinant of A from here turns out to this valid for any λ . So, when we put λ equal to 0 here, what we get is determinant of A equal to $(-1)^n$ into λ_1, λ_2 and so on λ_n .

So, determinant of the matrix A must be equal to $(-1)^n$ into product of the n Eigen values. You can see here, our matrixes $2 - 1$ and 2 , if you find the determinant of this matrix, what it is, is $4 - 1 = 3$. So, this is 3 and the Eigen values are 1 and 3. So, product of the Eigen values is 3 and determinant is 3 and here, we have 2×2 matrix, $(-1)^2 = 1$. So, determinant of A is equal to the

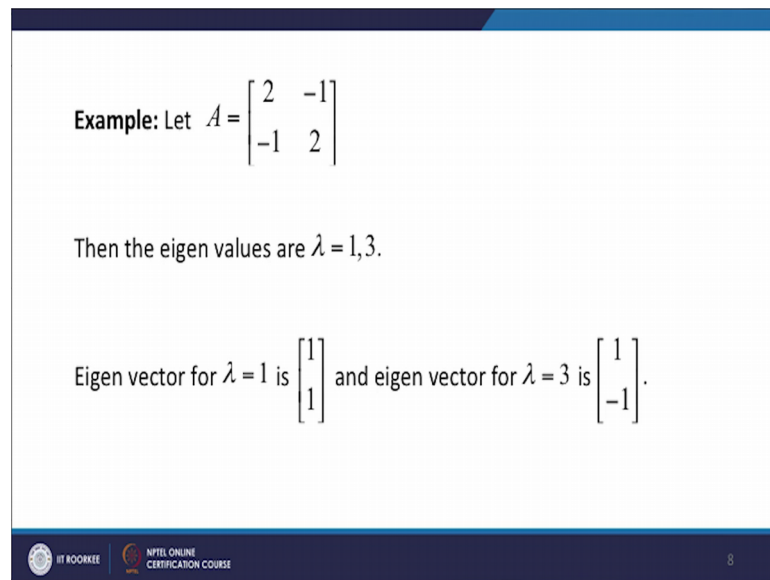

product of the Eigen values. So, this is another check on the calculation of the Eigen values of the given matrix. You can multiply all the Eigen values and then multiply by minus 1 to the power $30n$, where n is the order of the matrix. It should be equal to determinant of A and when we expand here, what we notice is that the coefficient of λ to the power $n-1$, which is $\lambda_1 + \lambda_2 + \dots + \lambda_n$ that should be equal to trace of the matrix. So, from here we can also prove that trace of the matrix must be equal to the sum of the Eigen values.

So, there are two checks on the calculation of the Eigen values. one is that trace of the matrix must be equal to sum of the Eigen values, and the other one is that product of the Eigen values into minus 1 to the power n must be equal to determinant A . This means that if 1 Eigen value is 0, then determinant of A is always 0; that means, if the determinant of A is equal to 0, then you must always get 1 Eigen value equal to 0. Now, we can find the Eigen vectors for the Eigen values $\lambda = 1$ and $\lambda = 3$. So, Eigen vector for $\lambda = 1$, the matrix is $\begin{bmatrix} 2 & -1 \\ -1 & 2 \end{bmatrix}$ and this is A equal to this.

So, we have the equation $(A - \lambda I)x = 0$. So, $(A - I)x = 0$. So, we subtract unit matrix from here. So, what we get is $\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}x = 0$ and then we have $x_1 - x_2 = 0$. So, we get two equations, one is $x_1 - x_2 = 0$ the other one is $-x_1 + x_2 = 0$. So, what we get is $x_1 = x_2$ and therefore, the vector x can be taken as $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$. The linearly independent Eigen vector A corresponding to $\lambda = 1$, can be taken as $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$ and the Eigen vector, similarly for $\lambda = 3$. So, this time we subtract $3I$ from $A - 3I = \begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix}$ into $x = 0$. So, this will be $\begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix}x = 0$. So, we get $-x_1 - x_2 = 0$ and then $x_1 + x_2 = 0$.

So, this will give you $x_1 + x_2 = 0$. So, we can take $x_2 = -1$ then, $x_1 = 1$. So, x is equal to $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$. So, we can find the Eigen vectors.

(Refer Slide Time: 39:00)

Example: Let $A = \begin{bmatrix} 2 & -1 \\ -1 & 2 \end{bmatrix}$

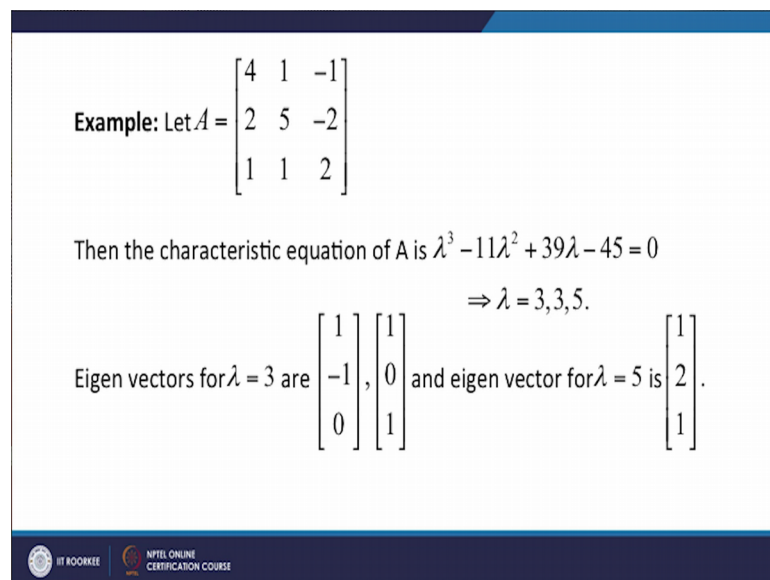

Then the eigen values are $\lambda = 1, 3$.

Eigen vector for $\lambda = 1$ is $\begin{bmatrix} 1 \\ 1 \end{bmatrix}$ and eigen vector for $\lambda = 3$ is $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 8

Corresponding to the two Eigen values 1 and 3, for 1 we have 1 - 1 and for 3 we have 1 minus 1.

(Refer Slide Time: 39:10)

Example: Let $A = \begin{bmatrix} 4 & 1 & -1 \\ 2 & 5 & -2 \\ 1 & 1 & 2 \end{bmatrix}$

Then the characteristic equation of A is $\lambda^3 - 11\lambda^2 + 39\lambda - 45 = 0$
 $\Rightarrow \lambda = 3, 3, 5$.

Eigen vectors for $\lambda = 3$ are $\begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}$, $\begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$ and eigen vector for $\lambda = 5$ is $\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

We can take one more example. Here, we are taking a 3 by 3 matrix. You can find the characteristic equation determinant of A minus lambda I equal to 0, expanding that we will get a cubic equation in lambda the equation, will come out to be lambda A cube minus 11 lambda square plus 39 lambda minus 45 equal to 0 up to a cubic equation, which is not difficult to solve. So, we can solve this equation. The values of lambda will

come out to be 3, 3, and 5. Now, you can see A, if you take the sum of the 3 Eigen values, what we get is 3 plus 3, 6, 6 plus 5, 11 and the trace of the matrix is 4 plus 5 plus 2, which is also 11. So, some of the Eigen values equals the trace of the matrix. You can see the determinant of A must be equal to minus 1 to the power N into product of the Eigen values, the product of the Eigen values is 5 into 3 into 3.

So, 45 multiplied by minus 1 to the power 3. So, we will get minus 45. So, you can find the determinant. Now, Eigen vectors: - let us find corresponding to the Eigen values here, we can notice that then Eigen value occurs twice. So, A - 3I. So, corresponding to Eigen value, lambda equals to 3. Let us see how many Eigen vectors we get; sometimes what we get is corresponding to a repeated Eigen value. We do not have the same number of Eigen vectors linearly independent on Eigen vectors and sometimes, we have the same number of Eigen vectors. So, here the Eigen value lambda equal to 3 occurs twice. So, its algebraic multiplicity is 2 and we shall see the geometric multiplicity. Geometric multiplicity is the number of Eigen vectors corresponding to the repeated Eigen value lambda equal to 3.

So, let us find the Eigen vector for lambda equal to 3. So, we have the matrix 4 1 1, and then we 41 minus 1.

(Refer Slide Time: 41:20)

$$A = \begin{bmatrix} 4 & 1 & -1 \\ 2 & 5 & -2 \\ 1 & 1 & 2 \end{bmatrix}$$

$$\lambda = 3$$

$$(A - 3I)x = 0$$

$$\begin{bmatrix} 1 & 1 & -1 \\ 2 & 2 & -2 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\Rightarrow x_1 + x_2 - x_3 = 0$$

$$x_1 = x_3 - x_2$$

$$x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} x_3 - x_2 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} x_3 \\ 0 \\ x_3 \end{bmatrix} + \begin{bmatrix} -x_2 \\ x_2 \\ 0 \end{bmatrix}$$

$$x = x_3 \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} + x_2 \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$$

Eigen vector for $\lambda = 1$:

$$A = \begin{bmatrix} 3 & -1 \\ -1 & 2 \end{bmatrix}$$

$$(A - I)x = 0$$

$$\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \Rightarrow x_1 = x_2$$

$$x_1 + x_2 = 0$$

$$x_1 = -x_2$$

$$x = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

Eigen vector for $\lambda = 3$:

$$(A - 3I)x = 0$$

$$\begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$x_1 + x_2 = 0$$

$$x_1 = -x_2$$

$$x = \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}$$

Then, we have 25 minus 2 and we have 1 1 2 lambda is equal to 3. Let us take lambda equal to 3. So the Eigen vector will be given by A minus 3 I x equal to 0. So, we subtract

the 3 times identity matrix of order 3 from A. So, what we will get is $\begin{pmatrix} 1 & 1 & 2 \\ 1 & 1 & 2 \\ 2 & 1 & 1 \end{pmatrix} - 3I$ and then, x is $x_1 \ x_2 \ x_3$.

Now, first equation will be $x_1 + x_2 - x_3 = 0$. Second equation is twice times the first equation. So, they are same equations. Third equation is also the same as the first equation. So, this gives you $x_1 + x_2 - x_3 = 0$. There is only one equation now, you can write $x_1 = x_3 - x_2$, to write the corresponding linear, find the linearly independent Eigen vectors. Let us write x is equal to $x_1 \ x_2 \ x_3$ and then, we can put the value of $x_1 = x_3 - x_2$ and here, we have $x_2 \ x_3$. Then, we can express it as a linear combination of $x_2 \ x_3$ times.

So, I will have broke bracket into like this, x_3 then 0 then x_3 and then I will write minus x_2 and x_2 and 0. So, that I can write x as a linear combination. So, x is equal to x_3 times $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$ and x_2 times $\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}$. So, the linearly independent Eigen vectors, associated with $\lambda = 3$ can be taken as $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$ and $\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}$. Every other Eigen vector will be a scalar linear combination of these 2 Eigen vectors and so, corresponding to the repeated Eigen value $\lambda = 3$. We also have the same number of linearly independent Eigen vectors here. So, algebraic multiplicity of 3 is 2 and the geometric multiplicity is also 2. There is a result which says that the geometric multiplicity does not exceed the algebraic multiplicity

Now, we can find the Eigen vector per $\lambda = 5$ in a similar manner. So, for the other Eigen value $\lambda = 5$.

(Refer Slide Time: 44:44)

$$\begin{aligned}
 & -x_1 + x_2 - x_3 = 0 \\
 & 2x_2 - 4x_3 = 0 \\
 & A = \begin{bmatrix} 4 & 1 & -1 \\ 2 & 5 & -2 \\ 1 & 1 & 2 \end{bmatrix} \quad \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} \& \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} \quad \text{Eigen vector for } \lambda = 5 \\
 & \lambda = 3 \\
 & (A - 3I)x = 0 \\
 & \begin{bmatrix} 1 & 1 & -1 \\ 2 & 2 & -2 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
 & \Rightarrow x_1 + x_2 - x_3 = 0 \\
 & \quad x_1 = x_3 - x_2 \\
 & (A - 5I)x = 0 \\
 & \begin{bmatrix} -1 & 1 & -1 \\ 2 & 0 & -2 \\ 1 & 1 & -3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \\
 & \begin{matrix} R_2 \rightarrow R_2 + 2R_1 \\ R_3 \rightarrow R_3 + R_1 \end{matrix} \Rightarrow \begin{bmatrix} -1 & 1 & -1 \\ 0 & 2 & -4 \\ 0 & 2 & -4 \end{bmatrix} x = 0 \\
 & \begin{matrix} R_3 \rightarrow R_3 - R_2 \end{matrix} \Rightarrow \begin{bmatrix} -1 & 1 & -1 \\ 0 & 2 & -4 \\ 0 & 0 & 0 \end{bmatrix} x = 0
 \end{aligned}$$

We have to subtract 5 I from A. So, when we do that, we get minus 1 1 minus 1. Then from 2 we subtract 5. So, 0 then minus 2, then we get 1 1 and we are getting minus 3. We can do elementary row operations on this to reduce it to an equivalent form. So, if I add A to the first row to the second row, this will change. We will simply do the operations on this coefficient matrix because this is 0. So, it will not change and x 1 x 2 x 3 is the column vector, these are the components of these columns.

So, that they do not of effect. So, this will be changing to minus 1 minus 1, and I multiply it in the first row by 2 and add 2 to the second row. So, we get here, 0, 2 and then minus 2 minus 2 and minus 4 and then, I add first row to the third row. So 0 then 2 and then minus 4. So, what I am doing here: 2 goes to R 2 2 R 1 and R 3 goes to R 3 plus R 1.

So, this system of equations will now change to this new system of equations. So, this is x equal to 0, now what we do in the second row, we can subtract from the third row. So, this will give R 3 goes to R 3 minus R 2 and we shall have minus 1 1 minus 1024 minus 4 and 0 0 x equal 0. So, third row becomes a 0 row. So, we are getting only two equations. So, we can write the equations now, minus x 1 plus x 2 minus x 3 equal to 0. This is the first equation and second equation is 0 into x 1 2 into x 2 minus 4 into x 3 is equal to 0. So, 2 x 2 minus 4 x 3 equal to 0 and we can solve this very easily.

(Refer Slide Time: 47:40)

$$\begin{aligned}
 & -x_1 + x_2 - x_3 = 0 \\
 & 2x_2 - 4x_3 = 0 \Rightarrow x_2 = 2x_3 \\
 & -x_1 + x_2 = 0 \\
 & x_1 = x_2 \\
 & x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} x_3 \\ 2x_3 \\ x_3 \end{bmatrix} = x_3 \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} \\
 & \begin{pmatrix} 1 & 1 & -1 \\ 2 & 2 & -2 \\ 1 & 1 & -1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \\
 & \Rightarrow x_1 + x_2 - x_3 = 0 \\
 & x_1 = x_3 - x_2
 \end{aligned}$$

$$\begin{aligned}
 & x = x_3 \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} + x_2 \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} \\
 & \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} \& \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} \quad \text{Eigen vector for } \lambda = 5 \\
 & (A - 5I)x = 0 \\
 & \begin{bmatrix} -1 & 1 & -1 \\ 2 & 0 & -2 \\ 1 & 1 & -3 \end{bmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \\
 & R_2 \rightarrow R_2 + 2R_1 \\
 & \Rightarrow \begin{bmatrix} -1 & 1 & -1 \\ 0 & 2 & -4 \\ 1 & 1 & -3 \end{bmatrix} x = 0 \\
 & R_3 \rightarrow R_3 + R_1 \\
 & \Rightarrow \begin{bmatrix} -1 & 1 & -1 \\ 0 & 2 & -4 \\ 0 & 2 & -4 \end{bmatrix} x = 0 \\
 & R_3 \rightarrow R_3 - R_2 \\
 & \Rightarrow \begin{bmatrix} -1 & 1 & -1 \\ 0 & 2 & -4 \\ 0 & 0 & 0 \end{bmatrix} x = 0
 \end{aligned}$$

So the second equation gives x_2 equal to $2x_3$. Let us put the value there, in the first 2 equations or minus x_1 , then x_2 is $2x_3$ minus x_3 is x_3 . So, we get x_1 equal to x_3 . So, x is equal to $x_3 \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$ and x_3 . So, I can write it as x_3 times $\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$. So, $\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$ is the linearly independent Eigen vector associated to the Eigen value λ equal to 5.

So, this is how we find the Eigen values and the Eigen vector for this 3 by 3 matrix, with that I would like to conclude my lecture.

Thank you very much.
