Lecture - 16
Orthogonal Sets

Hello friends; are welcome to this lecture. In this lecture, will discuss the concept of orthonormal sets and then, after this is in this orthonormal set will discuss the method known as a gram Schmidt orthogonalization process to obtain orthonormal set from a given set. So, first let us discuss the concept of inner product by which we can define the term orthogonal. So here, we discuss orthogonal and then, orthonormal be set of vectors.

(Refer Slide Time: 00:56)

In this section, we discuss the orthogonal and orthonormal basis of subspaces of \mathbb{R}^n , which are important in applications. We start with a definition of an orthogonal set of vectors in \mathbb{R}^n .

Definition

Let V be a vector space over \mathbb{F} . An inner product on V is a function that assigns, to every ordered pair of vectors x and y in V , a scalar in \mathbb{F} , denoted $\langle x, y \rangle$, such that for all x, y , and z in V and all c in \mathbb{F} , the following conditions hold:

- (a) $\langle x + z, y \rangle = \langle x, y \rangle + \langle z, y \rangle$.
- (b) $\langle cx, y \rangle = c \langle x, y \rangle$
- (c) $\overline{\langle x, y \rangle} = \langle y, x \rangle$, where the bar denotes complex conjugation.
- (d) $\langle x, x \rangle > 0$ if $x \neq 0$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So, first we define inner product. So, let V be a vector space over \mathbb{F} \mathbb{F} is a scalar field here, it may \mathbb{R} or \mathbb{C} and inner product on V is a basically a function from $V \times V$ to \mathbb{F} plus union 0 , that assigned to every order period of vectors x and y in V a scalar in \mathbb{F} , which is denoted as in inner product x with y such that, for all x, y and z in V and all the scalars in \mathbb{F} the following few conditions hold.

So, first condition says that, inner a product of x plus z with y is equal to inner a product of x with y plus inner a product z with y here. So, this condition shows that this inner a product function is linear with respect to first variable and second condition is that, $c \langle x, y \rangle$ is equal to c inner product of x comma y . So, here these 2 to a and b is simply

represent that, our inner product is linear with respect to the first variable, that and then c which sees that conjugated bar or conjugate of inner product of x comma y is equal to inner a product of y comma x where, this bar represent the complex conjugate conjugation and last one is that, inner a product of x with x is greater than 0 if x is nonzero.

So, this is the definition of inner product, which is denoted by this symbol symbol and it satisfies the following properties now, let us consider set an example.

(Refer Slide Time: 02:56)

Example
 For $x = (a_1, a_2, \dots, a_n)$ and $y = (b_1, b_2, \dots, b_n)$ in \mathbb{R}^n . We may define

$$\langle x, y \rangle = \sum_{i=1}^n a_i \bar{b}_i.$$

Then, we may prove that $\langle \dots \rangle$ actually is an inner product on V .

Definition
 Let $B = \{v_1, v_2, \dots, v_k\}$ be a set of vectors in \mathbb{R}^n . Then B is called an orthogonal set, if

$$\langle v_i, v_j \rangle = 0, \text{ whenever } i \neq j.$$

NPTEL ONLINE CERTIFICATION COURSE 3

So, let us says x is equal to a1 to a n and y equal to b1 to b n or 2 vectors in F n and then, we may define our inner product x with y a summation i equal to 1 to n a i b i is star. So, here we can verify that, this satisfy the properties listed here listed as ab cd I am not proving it and I am ask you people to verify with that, this is an inner product on V and here if this F is scalar field are then, here we can reduces as this inner product is reduce to i equal to 1 to n a i b i. So, in case of real vector space we have i equal to 1 1 to n a i b i. Now, now with the help of this inner product we try to define what is known as orthogonal set ? So, let be is a set having v1 to v k as element in Rn.

So, here v is equal to v 1 to v k be a set of vectors in R n. So, all these members v 1 to v k vectors in Rn then, B is called an orthogonal set if inner product of v i with v j is equal to 0 whenever, i is not equal to j. So, it means that if we take inner product of v 1 with any vector remaining any vector reaming here then, it is inner product which is defined

earlier must be 0. So, if a set having this property we call this set as orthogonal set and vectors are known as orthogonal vectors. So, let us consider certain one example.

(Refer Slide Time: 04:45)

Example

Let $B = \{v_1, v_2, v_3\} \subseteq \mathbb{R}^3$, where

$$v_1 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, v_2 = \begin{bmatrix} -2 \\ 1 \\ 1 \end{bmatrix} \text{ and } v_3 = \begin{bmatrix} 0 \\ -1 \\ 1 \end{bmatrix}$$

Then B is an **orthogonal** set in \mathbb{R}^3 , since

$$\langle v_1, v_2 \rangle = \langle v_2, v_3 \rangle = \langle v_3, v_1 \rangle = 0$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

So, here we let we take a set B in a consisting these 3 element v_1, v_2, v_3 were v_1 is equal to 1 1 1, v_2 is minus 2 1 1 and v_3 0 minus 1 and 1. So, here we want to show that, this B is a orthogonal set. So, to show that it is orthogonal set we need show see that, v_1 inner a product of the v_1 with v_2 and v_3 is 0 similarly, if you take inner product of v_2 with v_1 and v_3 R 0 similarly the same process is true for v_3 also. So, if you look at inner a product of v_1 and v_2 you look at here, just multiply component by. So, it is 1 minus 2 let be write here.

(Refer Slide Time: 05:40)

$$B = \{v_1, v_2, v_3\} \subseteq \mathbb{R}^3$$

$$v_1 = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, v_2 = \begin{pmatrix} -2 \\ 1 \\ 1 \end{pmatrix}, v_3 = \begin{pmatrix} 0 \\ -1 \\ 1 \end{pmatrix}$$

$$x, y \in \mathbb{R}^n$$

$$\text{then } \langle x, y \rangle = \sum_{i=1}^n x_i y_i, \quad n=3 \quad \langle x, y \rangle = \langle y, x \rangle$$

$$\langle v_i, v_j \rangle = 0 \quad (i \neq j)$$

$$\langle v_1, v_2 \rangle = 1 \cdot (-2) + 1 \cdot 1 + 1 \cdot 1 = 0 = \langle v_2, v_1 \rangle$$

$$\langle v_1, v_3 \rangle = 1 \cdot 0 + 1 \cdot (-1) + 1 \cdot 1 = 0 = \langle v_3, v_1 \rangle$$

$$\langle v_2, v_3 \rangle = -2 \cdot 0 + 1 \cdot (-1) + 1 \cdot 1 = 0 = \langle v_3, v_2 \rangle$$

So, example here is that, we have to show that the the set B which consists of the 3 vectors v_1, v_2, v_3 is a subset of \mathbb{R}^3 v_1 is given by $1 \ 1 \ 1$, v_2 as $-2 \ 1 \ 1$ and v_3 as $0 \ -1 \ 1$ then, this set B is a orthogonal set to show that, it is orthogonal set we have to show that inner product of v_1 with v_2 and v_3 is 0 and similarly, inner product of v_2 with the v_3 is 0. So, we recall the definition of inner product, that if we take 2 element $x \ y$ in \mathbb{R}^n and then, inner product $x \ y$ is given by summation i equal to 1 to n $x_i y_i$.

So, it is basically component wise multiplication here. So, here since we are taking real vectors. So, we are not putting any bar here. So now, let us defined in inner product of v_1 and v_2 . So, let us see the component wise. So, 1 in to -2 . So, that is 1 in to -2 plus 1 in to 1 here and then 1 into 1 . So, this is see inner product if you sum them up then it is coming out to be 0 this is $-2 + 1 + 1$. So, it is coming out to be 0. Similarly, it is a here v_1 with the v_3 here. So, it is v_1, v_3 means, component wise multiplication. So, 1 into 0 plus 1 in to -1 plus 1 in to 1 here. So, this will be giving this will give $-1 + 1$ and this will give 0. So, it is coming out to be 0.

Now, by the property of inner product we know that, we have this property that inner product of $x \ y$ is equal to inner product of y with x bar know since, we are considering their vector space. So, there is no bar here. So, it means that inner product of x with y is same as inner product of y with x . So, taking this in mind then inner product of $v_1 \ v_2$ is equal to 0 implies that it is same as v_2, v_1 . Similarly, inner product of v_1, v_3 is same as inner product of $v_3 \ v_1$ here. Now, we want to show the inner product of v_2 with v_3 is

also 0; so, for that is minus 2 into 0 plus 1 into minus 1 plus into 1 that is coming out to be 0 here.

So, this is same as v_3 with v_2 by the same property. So, here what we have shown here, we have shown that inner product of v_i with v_j is equal to 0 where, i is not equal to j here. So, it means that, these vectors of this set B satisfied this property it means that, this set is an orthogonal set and vectors are orthogonal vectors here. Now, moving on next theorem where we want to understand the property of orthogonal set one important property of orthogonal set this statement of the this theorem says let B ah, which set of k elements we want to v_k be a set of nonzero vectors in \mathbb{R}^n , if B is an orthogonal set then B is linearly independent. So, B is orthogonality implies the linearly independence. So, to prove this let us say that.

(Refer Slide Time: 08:44)

Theorem
 Let $B = \{v_1, v_2, \dots, v_k\}$ be a set of nonzero vectors in \mathbb{R}^n . If B is an orthogonal set, then B is linearly independent.

Proof. Suppose that B is an orthogonal vector in \mathbb{R}^n . To show that B is linearly independent, consider the equation

$$\sum_{i=1}^k a_i v_i = 0 \quad (1)$$

Taking the inner product of v_i , $1 \leq i \leq k$, on both sides of (1),

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 5

Suppose, that B is an orthogonal vectors B is orthogonal set set an \mathbb{R}^n to show that, B is linearly independent consider this equation summation i equal to 1 to k $a_i v_i$ equal to 0 what we want to show here that, all these coefficient a_i are nothing but 0 or we can have only a trivial solution of this equation. So, of to show that all a_i is there 0 we take the help of orthogonality, that all these v_1 to v_k are orthogonal vectors (Refer Time: 9:34). So, what we do here we take the inner product of v_i , but i is running from 1 to k on both sides of this equation.

(Refer Slide Time: 08:44)

we get

$$a_1 \langle v_i, v_1 \rangle + a_2 \langle v_i, v_2 \rangle + \dots + a_k \langle v_i, v_k \rangle = 0.$$

Since, the vectors v_1, v_2, \dots, v_k are mutually orthogonal, it follows that

$$a_i \|v_i\|^2 = 0.$$

Since, each v_i is a nonzero vector, it is immediate that $a_i = 0$. Hence \mathcal{B} is linearly independent.

Definition

Let $\mathcal{B} = \{u_1, u_2, \dots, u_k\}$ of vectors in \mathbb{R}^n , then \mathcal{B} is called an orthonormal set if \mathcal{B} is an orthogonal set of unit vectors in \mathbb{R}^n , i.e. if the following two conditions hold:

- The vectors u_1, u_2, \dots, u_k are mutually orthogonal.
- $\|u_1\| = \|u_2\| = \dots = \|u_k\| = 1$

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

So, taking this inner product we have a_1 let us see, a_1 inner product v_i with v_1 plus a_2 inner product with v_2 plus. So, on a k inner product of v_i with v_k equal to 0. Now, here we already know that, that v_i is are orthogonal vectors. So, it means that inner product of v_i with v_j is equal to 0 if j is not equal i . So, it means that if i is not equal to j . So, it means that only i th factor will come out to be nonzero rest of all 0. So, since the vectors v_1 to v_2 are mutually orthogonal it follows that, v_i norm of v_i square is equal to 0.

So, we want to show that this set is a \mathcal{B} , which is a set of v_1 to v_k which is given as orthogonal set we want to show that, this is an linearly independent set. So, to show that, these vectors are linearly independent vectors we have we have to consider this linear combination i equal to 1 to k $a_i v_i$ equal to 0 here, and then we want to show that all these a_i is are 0 for all i equal to 1 to k . So, far that let us take the inner product of these in the equation with v_i . So, here since we are taking inner product with v_i . So, we are considering this dummy variable as j variable.

(Refer Slide Time: 10:35)

$$\begin{aligned}
 B &= \{u_1, \dots, u_k\} \\
 \sum_{i=1}^k a_i u_i &= 0 \Rightarrow a_i = 0 \quad \forall i=1, \dots, k \\
 \text{Taking inner product with } u_i & \\
 \langle u_i, \sum_{j=1}^k a_j u_j \rangle &= \langle u_i, 0 \rangle = 0 \\
 &= \sum_{j=1}^k a_j \langle u_i, u_j \rangle = 0 \Rightarrow \cancel{a_1 \langle u_i, u_1 \rangle} + \dots + \underbrace{a_i \langle u_i, u_i \rangle}_{\neq 0} + \dots = 0 \\
 &\Rightarrow a_i \langle u_i, u_i \rangle = 0 \\
 \underbrace{a_i \langle u_i, u_i \rangle}_{\neq 0} &= 0 \Rightarrow a_i = 0, \quad \forall i=1, \dots, k \\
 \|u_i\| &= \sqrt{\langle u_i, u_i \rangle}
 \end{aligned}$$

\mathbb{R}^n
 $\{e_i \mid 1 \leq i \leq n\}$
 $e_i = \begin{pmatrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{pmatrix} \rightarrow i^{\text{th}}$

So, inner product of v_i with respect with j equal to 1 to k a j , v_j equal to inner product of v_j with 0 here. Now, inner product of with v_j with 0 is nothing but 0 here. Now, he here use in the property of inner product we can write this as summation j equal to 1 to k a j inner product of v_i with v_j is equal to 0. Now, we already know that, these are orthogonal set of vectors here. So, it means that v_i is equal to v_j inner product of v_i with v_j is equal to 0 for all i not equal to j . So, it means that it means that, for i equal j only this inner product is nonzero for all other it is simply 0. So, we have only one time left that is a j inner product with v_j with v_j is equal to 0. So, this is nothing but, this implies that a j this is v_j v_j is equal to 0 now, this v_j is a nonzero vectors. So, this implies that this a j is equal to 0 here.

Now, this can be done for any j here. So, it means that this j is we can write it that, j for all j equal to 1 to k here. Now, here one thing we try to note it down that, here we can define norm of v_j as under root of inner product with v_j with v_j . So, basically this quantity is nothing but, norm of v_j square and non-if v_j is nonzero than norm of v_j square is nonzero and hence a j has to be 0 and this we can repeat for any j here. So, j is equal to 1 to k means, all a j is are simply 0. So, here we are considering the inner product of v_i with this linear this linear combination. So, here if we take we use a property of inner product then, this can be written as a equal to 1 to k a j inner product of v_i with v_j equal to 0. Now, since we have that these vectors are orthogonal vectors. So, it means that this inner product of v_i with v_j is equal to 0 until i is not equal to j .

So, it means that, only for j equal to i we have nonzero by quantity for rest it is simply a 0 value. So, it means that if we write it here, this nothing but $a_1 v_1$ with v_1 plus. So, on a_i inner product with v_i with v_i plus a_{i+1} inner product of v_i with v_{i+1} and so on equal to 0. Now, we know this is going to be 0 because i is not equal to $i+1$.

So, this is 0 same this is 0 and all other terms are 0 only non0 term left is this. So, it means that a_i inner product of v_i with v_i is equal to 0 now, this is what this is the norm of v_i square because, we know this relation than norm v_i is given as as under root of inner product of v_i with v_i . So, we can say that this norm is square is norm 0 because, v_i is taken as nonzero vectors. So, it means that a_i has to be 0. So, it means at this we can say for all i equal to 1 to k . So, it means that this summation i equal to k $a_i v_i$ equal to 0 implies that all $a_j = 0$.

So, this implies that if B is orthogonal set then, B is a n linearly independent set. So, moving on next definition of orthogonal set. So, let B set of k vectors in R^n then, B is called an orthogonal set if B is an orthogonal set and B is an orthogonal set of unit vectors in R^n it means that, set B satisfy the following 2 condition first the vectors u_1 to u_k are mutually orthogonal and second that, norm of each vector is equal to 1 here. So, it means that this set B is an orthonormal set if these vectors are orthogonal and in up and norm of each vectors is equal to 1.

So, let us consider some example of orthonormal set. So, the standard ordered basis for F^n is an orthonormal basis for F^n for example, if we consider R^n then, standard orthogonal basis R^n is basically e_i , e_i is I think we can write it like this that if we have R^n here then, standard basis are e_i i is from 1 to n here, what is e_i here? e_i is basically vectors were all other it is simply 0 only the i th place it is nonzero and it is equal to 1.

(Refer Slide Time: 16:11)

Example
The standard ordered basis for \mathbb{R}^n is an orthonormal basis for \mathbb{R}^n .

Example
The set $\left\{\left(\frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}}\right), \left(\frac{2}{\sqrt{5}}, \frac{-1}{\sqrt{5}}\right)\right\}$ is an orthonormal basis for \mathbb{R}^2 .

Definition
Let S be a subspace of \mathbb{R}^n , and let $\mathcal{B} = \{u_1, u_2, \dots, u_k\}$ be a basis for S . We say that \mathcal{B} is an orthogonal basis for S if \mathcal{B} is an orthogonal set. We say that \mathcal{B} is an orthonormal basis for S if it is an orthonormal set.

BY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

So, this e_i is basically this set is an orthonormal basis for \mathbb{R}^n here. So, that you can easily verify that, if he take the inner product of e_i with e_j , j is not equal to i you can see that, inner product is going to be 0 and if you consider the inner product of e_i with e_i itself, which is nothing but norm of e_i square it is coming out to be 1 only. Now, looking at the second example we have another example we says that, this set of 2 vectors is $\left(\frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}}\right)$ and $\left(\frac{2}{\sqrt{5}}, \frac{-1}{\sqrt{5}}\right)$ is an orthonormal basis for \mathbb{R}^2 .

So, how we can look at here first of all we have to show that, this is orthonormal set and then, we can show that it is orthonormal basis. So, to show that it is a basis here since, dimension of \mathbb{R}^2 is 2 and if you can show that this set is an orthogonal then, we know that it is a linear independent also and hence, the dimension of the vector subspace, which is span by this set going to be 2 and hence, than we can prove that this is going to be in orthogonal basis for \mathbb{R}^2 let us verify that, this is orthogonal this for \mathbb{R}^2 . So, we want to show that this set \mathcal{B} , which is given as set of 2 vectors $\left(\frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}}\right)$ and another vector given as $\left(\frac{2}{\sqrt{5}}, \frac{-1}{\sqrt{5}}\right)$ this set is going to be \mathcal{B} an orthonormal basis for \mathbb{R}^2 .

(Refer Slide Time: 18:23)

$$B = \left\{ \underbrace{\left(\frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}} \right)}_{v_1}, \underbrace{\left(\frac{2}{\sqrt{5}}, \frac{-1}{\sqrt{5}} \right)}_{v_2} \right\} \text{ is an orthonormal basis for } \mathbb{R}^2.$$

B is an orthogonal set.

$$\langle v_1, v_2 \rangle = \frac{1}{\sqrt{5}} \times \frac{2}{\sqrt{5}} + \frac{2}{\sqrt{5}} \times \left(\frac{-1}{\sqrt{5}} \right) = 0$$

B is a LI set

$$\dim(\text{Span}(B)) = 2$$

$$\langle v_1, v_1 \rangle = \|v_1\|^2 = \frac{1^2}{5} + \frac{2^2}{5} = \frac{1+4}{5} = 1$$

$$\|v_2\| = \sqrt{\langle v_2, v_2 \rangle} = \sqrt{\frac{2^2}{5} + \frac{(-1)^2}{5}} = \sqrt{\frac{4+1}{5}} = 1$$

So, what we try to prove first is that, this, this B is an orthogonal set. So, first we show that, B is a orthogonal set. So, to show that we need we show that inner product of v_1 with v_2 is going to be 0. So, here we have 1 upon root 5 in to 2 by root 5 plus 2 by root 5 in to minus 1 upon root 5. So, if you look at nothing but 0 here. So, it means that, B is consist only 2 element and those 2 elements r orthogonal to each other.

So, we can say that B is an orthogonal set. So, just by orthogonality we can show that by pe previous result B is an a linearly independent set here. So, that is all, all clear, next thing we want to show that, that each factor has a norm 1. So, to show that it has norm 1 let us take the inner product of v_1 with v_1 , which is nothing but norm v_1 square. So, if you calculate this, this is nothing but v_1 with v_1 is equal to 1 by root 5 with 1 by root 5 plus 2 by root 5 into 2 by root 5.

So, which is nothing but 1 by 5 plus 4 by 5 it is coming out to be 1 here. Similarly, we can verify that norm of v_2 is going to be in another root of inner product of v_2 with v_2 is going to be 1, this you want to show here let us calculate the inner product of this. So, inner product of v_2 with v_2 is going to be 2 by root 5 into 2 by root 5 plus minus 1 upon root 5 into minus 1 upon root 5. So, if you calculate this is coming out to be 1 also. So, it means that B is an orthogonal set and every vector in this set has a norm 1.

So, it is mean it means that B is an orthonormal set here set of \mathbb{R}^2 . Now, we already know that, this being a orthogonal set it is a l i set. So, it means that span of B is going to be vector space having dimension 2. So, dimension of span of B is going to B 2 and it is

going to be a subset of \mathbb{R}^2 . So, it means that this is going to be a basis for \mathbb{R}^2 here. So, we already know that either we do it like this or we can show that since, the dimension of \mathbb{R}^2 is 2 and the we have a set having 2 linearly independent vectors than, this is going to be a basis for \mathbb{R}^2 here.

So now, let us defined the terms of orthonormal basis and orthogonal basis. So, for that let us take subspace of \mathbb{R}^n and let B is a set is a subset S and which is a which represent basis for S is we say that, B is an orthogonal basis if this set is an orthogonal set and we say that, B is an orthonormal basis if the set is an orthonormal set. So, we have show that , the set is going be an orthonormal basis is for \mathbb{R}^2 here because, we have shown that this a basis and it is a orthonormal set.

(Refer Slide Time: 22:11)

Theorem

Let V be an inner product space and $S = \{v_1, v_2, \dots, v_k\}$ be an orthogonal subset of V consisting of nonzero vectors. If $y \in \text{span}(S)$, then

$$y = \sum_{i=1}^k \frac{\langle y, v_i \rangle}{\|v_i\|^2} v_i$$

Proof.

Write $y = \sum_{i=1}^k a_i v_i$ where $a_1, a_2, \dots, a_k \in \mathbb{F}$. Then, for $1 \leq j \leq k$, we have

$$\langle y, v_j \rangle = \left\langle \sum_{i=1}^k a_i v_i, v_j \right\rangle = \sum_{i=1}^k a_i \langle v_i, v_j \rangle = a_j \langle v_j, v_j \rangle = a_j \|v_j\|^2$$

So $a_j = \frac{\langle y, v_j \rangle}{\|v_j\|^2}$, and the result follows. □

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 8

Now, let us move on to next example next theorem we say that, let V be an inner product space and S is equal to be v_1 to v_k , B an orthogonal subset of V consisting of nonzero vectors only.

So, it means that all this v_1 to v_k or nonzero vectors and if y belong to span of S then y can be written as i equal to 1 to k y with v_i divided by norm v_i square into v_i . So, this is it means that we can find out say linear coefficient of v_i as inner product of y with v_i divided by norm of v_i square. So, in this theorem we want to show that, how we represent y in terms of linear combination of v_i . So, we want to show that here, the finding out the process of finding the coefficients are not more easier than the then, the

set if we this set is not orthogonal then finding the efficient are difficult, but if it is an orthogonal set then, finding the then coefficient of v_i or quite easier.

So, let us consider the proof of this. So, let us a y equal to submission equal to 1 to k a $i v_i$ were these a i is are coming from a scalar field then for 1 less than j less than k we take the inner product of y with v_j . So, inner product of y with v_j is equal to summation i equal to 1 to k a $i v_i$ with v_j is equal to now, here we take the take the property of inner product and we can write this as summation equal to k a i inner product of v_i with v_j . Now, we know that this inner product of v_i with v_j is going to be nonzero only when i is equal to j . So, all other it is going to be 0 . So, this means that only for i equal to j this have a nonzero value and this is nothing but, a j inner product of v_j with v_j . Now, we that inner product of v_j with v_j is going to be norm of v_j is square it means, that inner product of y with v_j is going to be a_j into norm of v_j square now, we already know that these v_j are nonzero.

So, this nom is going to be norm 0 quantity. So, we can write down this a j as inner product of y v_j divided by norm of v_j square. So, it means that coefficient of v_j can be obtained very easily, but if this v_i is are not orthogonal then, this cannot a be achieved so easily. So, it means that in case of orthogonal orthogonal basis coefficient are finding coefficient are quite easy.

(Refer Slide Time: 25:08)

Corollary

Let $B = \{v_1, v_2, \dots, v_k\}$ be an orthonormal basis for V . If $x = \sum_{i=1}^k \alpha_i v_i$ and $y = \sum_{i=1}^k \beta_i v_i$ then $\langle x, y \rangle = \sum_{i=1}^k \alpha_i \beta_i$

Proof.

As $\langle x, y \rangle = \langle \sum_{i=1}^k \alpha_i v_i, \sum_{j=1}^k \beta_j v_j \rangle = \sum_{i=1}^k \sum_{j=1}^k \alpha_i \beta_j \langle v_i, v_j \rangle$. Since B is an orthonormal basis, it follows that $\langle x, y \rangle = \sum_{i=1}^k \alpha_i \beta_i$ □

Corollary

(Parseval's Formula) Let $B = \{v_1, v_2, \dots, v_k\}$ be an orthonormal basis for V . If $x = \sum_{i=1}^k \alpha_i v_i$, then $\|x\| = \sqrt{\alpha_1^2 + \alpha_2^2 + \dots + \alpha_k^2}$.

Now, moving on the corollary of this. So, we have that let B be an orthonormal basis for V and if x is written as summation equal to k $\alpha_i v_i$ and y is written as summation i equal to k $\beta_j v_j$ then, inner product of inner product of x y is nothing but, inner product of coordinates of x and y that is inner product of α_i and β_j equal to 1 to k $\alpha_i \beta_j$.

So, inner product of x y is nothing but inner product of coordinates of x and y here. So, to prove this we simply take this as inner product of x comma y , which is equal to summation i equal to 1 to k $\alpha_i v_i$ comma summation j equal to 1 to k $\beta_j v_j$ here, we are taking the inner product. So, we are taking different dummy indices. Now, this can be written as summation i equal to 1 to k summation j equal to 1 to k $\alpha_i \beta_j$ inner product of v_i with v_j . Now, again using the same property that v_i is orthogonal to each other. So, it means that this will have a nonzero value only when this i is equal to j all others it is going to be 0 .

So, it means that taking j has i we can say that this inner product of x y is reduces is to summation i equal to 1 to k $\alpha_i \beta_i$. So, this corollary says that when we have a orthonormal basis, then inner product of vectors here x and y is nothing but inner product of quadrant vectors. So, that is one use of orthonormal basis second corollary simply say that, how to find out orthonormal? How to find a norm of a given vectors x ? So, we have let B is we want to $v_k B$ an orthonormal basis for V and if x can be written as summation i equal to 1 to k $\alpha_i v_i$ then, norm of x can be given as summation under under root of α_1^2 plus α_2^2 plus α_k^2 square. So, this can be proof of this corollary can be given very easily with the help of previous corollary. So, here we replace y by x then, it is nothing but inner product of x comma x is going to be summation equal i to 1 to k α_i^2 square.

So, norm is going to be inner product is square root of inner product and the proof of this parsevals formula follows.

(Refer Slide Time: 28:06)

So, it means that if you look at what we have seen here, that we have a suppose a vector space v and then we have a vector subspace $s \subset v$ and then we have a set B which is given as say v_1 to v_k as and as a an orthogonal set then we have seen that, B n an orthogonal set it satisfy 2 property first thing that B is a LI set first property, which we have proved and a second property that, if this is a basis if B is a basis then, any element we which is written as summation $\alpha_i v_i$ from 1 to k then, this α_i is can be obtained very easily as we inner product with the v_i divided by inner product of v_i with v_i and that is easily possible because this set is an orthogonal set. So, inner product of any 2 element here inner product of v with w is nothing but, inner product of coordinate vector of v and coordinate vector of w .

So, inner product of v, w is nothing but, inner product of coordinate vectors of v and w , that is what is the meaning of this corollary here. Now, moving on next theorem we say that let cube $n \times n$ orthogonal matrix and if x, y are 2 vectors \mathbb{R}^n than inner product of Qx with Qy is nothing.

(Refer Slide Time: 30:00)

Theorem
 Let Q be an $n \times n$ orthogonal matrix. If $x, y \in \mathbb{R}^n$, then
 (a) $\langle Qx, Qy \rangle = \langle x, y \rangle$
 (b) $\|Qx\| = \|x\|$

Proof(a) Let $B = \{q_1, q_2, \dots, q_n\}$ be an orthonormal basis for \mathbb{R}^n . Let
 $x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}$ and $y = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}$ Note that
 $Qx = [q_1 \ q_2 \ \dots \ q_n] \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} = \sum_{i=1}^n x_i q_i$

BY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

But inner product of x and y and B part is that norm of Qx is same as norm of x . So, it means that, if we have an orthogonal say matrix A . So, product of orthogonal matrix and a vector does not change the norm of the vector here. So, to prove this let us consider that let B is q_1 to q_n B and orthonormal basis for \mathbb{R}^n and let x is a vector given as x_1 to x_n and y as y_1 to y_n ok. So, what is given here is at Q is an orthogonal matrix.

(Refer Slide Time: 30:38)

Let $Q = [q_1 \dots q_n]$ be an orthogonal matrix.
 $\Rightarrow Q^T Q = I \Rightarrow q_i^T q_j = \delta_{ij}$

$B = \{q_1, \dots, q_n\}$ be an orthonormal basis for \mathbb{R}^n .

$x = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix}, y = \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix}$

$Qx = [q_1 \dots q_n] \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} = \sum_{i=1}^n x_i q_i$

$\langle Qx, Qy \rangle = \left\langle \sum_{i=1}^n x_i q_i, \sum_{j=1}^n y_j q_j \right\rangle = \sum_{i=1}^n x_i \langle q_i, \sum_{j=1}^n y_j q_j \rangle = \sum_{i=1}^n x_i \left(\sum_{j=1}^n y_j \langle q_i, q_j \rangle \right) = \sum_{i=1}^n x_i y_i = \langle x, y \rangle$

$A = [q_1, q_2]$
 $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \\ e_1 & e_2 \end{bmatrix}, x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$
 $Ax = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} a_{11}x_1 + a_{12}x_2 \\ a_{21}x_1 + a_{22}x_2 \end{bmatrix}$
 $= x_1 \begin{bmatrix} a_{11} \\ a_{21} \end{bmatrix} + x_2 \begin{bmatrix} a_{12} \\ a_{22} \end{bmatrix} = x_1 q_1 + x_2 q_2$

So, let Q is given as this matrix q_1 to q_n where, q_n represent the first column of this orthogonal matrix and q_1 represents the another column of this orthogonal matrix. So, since orthogonal matrix means $Q^T Q = I$ and then, we can say that this is nothing but a saying that $q_i^T q_j$ is nothing but, δ_{ij} where δ is a Kronecker delta

function. So, it means that if i is not equal to j then, q_i is an inner product of q_i with q_j is going to be 0 and if i equal to j then q_i inner product of q_i with q_i is going to be 1. So, it means that this q_1 to q_n are orthonormal vectors here. So, with the help of these n orthonormal vectors we can consider a basis for R^n and this basis is nothing but, an orthonormal basis for R^n . So, then we can consider q of x where, x we can consider this as say x_1 to say x_n . Similarly, we can consider y as say y_1 to say y_n and then, consider q of x q is given as q_1 to q_n and here, x is given as x_1 to x_n and this we can write as summation say I equal to 1 to n $x_i q_i$ here.

So, So, this can be written as this product can be written as summation i equal to 1 to n $x_i q_i$ I will just take very simple example of this thing let us say that, we have a matrix a which is given as $a_{11}, a_{12}, a_{21}, a_{22}$ and we have a vector x , which is given as x_1 and x_2 and you want to show that, multiplying a matrix with a vector can be written as linear combination of columns of this matrix q . So, that is what we want to write it here that say that this is q_1 and this is q_2 . So, we want to find out a of x a of x is going to be what $a_{11}, a_{12}, a_{21}, a_{22}$ multiplied by the this x_1 and x_2 and this is what this can be written as $a_{11} x_1$ and plus $a_{12} x_2$ and here, we can write it $a_{21} x_1$ plus $a_{22} x_2$ and this we can write as equal to you can take x_1 out and this is nothing but, a_{11}, a_{21} plus x_2 this is nothing but a_{12}, a_{22} . So, it means that in terms of column if you want to write it then, this is nothing but $x q_1$ plus $x q_2$. So, it means that if you multiply if we write a as say q_1 and q_2 then $a x$ can be written as $x_1 q_1$ plus $x_2 q_2$.

So, similarly we can write down Qx and if q represented as this this kind that q_1 q_1 represent the columns of q then, this in this multiplication can be written as linear combination q_i . So, i equal to one to n $x_i q_i$. So now, to find out inner product Qx with q_i we can use this inner product of $x_i q_i$ with summation $y_j q_j$. So, let us use some other a dummy variable. So, let us use j here y_j and q_j i is from 1 to n and j is from 1 to n . So, to find out this is use the property of inner product and we can write down summation i equal to 1 to n x_i then, this will be written as q_i inner product summation j equal to 1 to n $y_j q_j$, right? And again, we can use the same property of inner product space.

So, using again the property of inner product we can write the this as equal to summation i equal to 1 to n x_i and then, we are taking these coefficient out j equal to 1 to n y_j and what is left here is inner product of q_i with q_j , right? And this is nothing but inner

product of Qx with Qy , right? Now, this is what we already know that these q_i s are orthonormal vectors here.

(Refer Slide Time: 35:28).

$$\begin{aligned} \langle Qx, Qy \rangle &= \sum_{i=1}^n x_i \sum_{j=1}^n y_j \langle q_i, q_j \rangle \\ &= \sum_{i=1}^n x_i y_i = \langle x, y \rangle \end{aligned}$$

$y = x$

$$\Rightarrow \langle Qx, Qx \rangle = \langle x, x \rangle$$

$$\Rightarrow \|Qx\|^2 = \|x\|^2$$

$$\Rightarrow \|Qx\| = \|x\|$$

$B = \{q_1, \dots, q_n\}$ be an orthonormal basis for \mathbb{R}^n

$$Qx = \begin{bmatrix} q_1 & \dots & q_n \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} = \sum_{i=1}^n x_i q_i$$

$$A = \begin{bmatrix} q_1 & q_2 \end{bmatrix} \quad x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

$$A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \\ t_1 & t_2 \end{bmatrix}$$

$$Ax = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \\ t_1 & t_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} a_{11}x_1 + a_{12}x_2 \\ a_{21}x_1 + a_{22}x_2 \\ t_1x_1 + t_2x_2 \end{bmatrix}$$

$$= x_1 \begin{bmatrix} a_{11} \\ a_{21} \\ t_1 \end{bmatrix} + x_2 \begin{bmatrix} a_{12} \\ a_{22} \\ t_2 \end{bmatrix} = x_1 q_1 + x_2 q_2$$

So, it means that if i is not equal to j then this is going to be 0. So, it means that we can write it i equal to 1 to $n \times i$ now, for j equal to i only we have a nonzero value. So, we can say that it is going to be y_i inner product of q_i with q_i now, again since we have this q_i 's are orthonormal. So, this is going to be 1. So, this is going to be one only and now, what we can write it this, this is nothing but inner product of x with y here. So, it means that inner product of Qx with Qy is nothing but, inner product of x with y here. So, it means that inner product of Qx with q_i is nothing but inner product of x with y when, q_i is going to be an orthogonal matrix.

So, if q is an orthogonal matrix the inner product Qx with q_i is same as inner product of x with y now, here if we replace this y as x then it is nothing but inner product of Qx with Qx is equal to inner product of x with x , which is nothing but norm of Qx square is equal to norm of x square. So, it means that it means that, norm of Qx is going to be norm of x here. So, it means that if you multiply this x by an orthogonal matrix then their norm is not going to change and this is a very, very important property and numeric linear algebra because, as far as possible whenever we do some kind of numerical computation we always try to do that numerical computation with the help of orthogonal operators.

Now, the property of orthogonal operator's orthogonal matrix, that it will not increase any kind of error. So, if there is any error in this x represent the error vector then, error vector is not going to propagate as we apply the orthogonal matrix over this. So, it means that this is very, very important property to be utilised later on. So, that is what is the proof we have considered here. So, here we are going to stop.

So, in this lecture what we have considered is we have considered the concept of inner product and with the help of inner product we have define the concept orthogonal set and we have seen certain property of orthogonal set that, even if we have a set which is orthogonal then it is automatically linearly independent then we have also seen that, if you want to write any vector in terms of these orthogonal vectors then, coefficient of these orthogonal vectors can be find out very easily and if with the help of these orthogonal vectors if we considered a orthogonal orthonormal basis of a vector space then, finding the coefficients are quite easy.

So, that we have seen here and in next lecture we want to see how to find out orthogonal set and orthonormal set from a given set of vectors. So, that is the content of next lecture. So, here we stop thank you for listening us.

Thank you.
