Lecture – 17
Gram Schmidt Orthogonalization and Orthonormal Bases

Hello friends. Welcome to this lecture. In this lecture, we will discuss the method known as Gram Schmidt orthogonalization method. Because in next lecture, if we recall, we have discussed the concept called orthogonal set and we have seen certain properties of orthogonal set. So, whenever we have the possibility, we always try to use orthogonal basis rather than standard rather than any given basis.

So, in this lecture, what we try to do here? We try to find out orthogonal basis from a given basis. So, it means that given a linearly independent vectors, we try to find out a new set of vector having the same number of element and with the additional property that; now the additional set of factors is orthogonal rather than only linear independent. So, that is the content of this gram Schmidt organization process.

(Refer Slide Time: 01:27)

Gram-Schmidt process

The **Gram-Schmidt process** takes a set of linearly independent vectors $S = \{v_1, v_2, \dots, v_n\} \in \mathbb{R}^m$, and transforms them into a set of orthonormal vectors $S' = \{e_1, e_2, \dots, e_n\}$. The orthonormal set $S' = \{e_1, e_2, \dots, e_n\}$ spans the same n -dimensional subspace as S .

Theorem
Let V be an inner product space and $S = \{w_1, w_2, \dots, w_n\}$ be a linearly independent subset of V . Define $S' = \{v_1, v_2, \dots, v_n\}$, where $v_1 = w_1$ and

$$v_k = w_k - \sum_{j=1}^{k-1} \frac{\langle w_k, v_j \rangle}{\|v_j\|^2} v_j \quad \text{for } 2 \leq k \leq n \quad (2)$$

Then, S' is an orthogonal set of nonzero vectors such that $\text{span}(S') = \text{span}(S)$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So, the Gram Schmidt orthogonalization process takes a set of linearly independent vectors S . So, let us say that we have a set S be consisting these n element v_1 to v_n . Now these S is basically some linearly independent set of \mathbb{R}^m and transform this set S

into a new set of vectors as $S = \{e_1, \dots, e_n\}$ where e_1, \dots, e_n 's are orthogonal vectors and norm of each vector is 1. So, it means that S is going to be orthonormal vectors.

So, that is the use of Gram Schmidt organization process and the property it retained that if S spans certain subspace then S will span the same subspace. So, it means that the orthonormal set S spans the same n dimensional subspace as S . So, S generate n dimension vector subspace of R^m .

Similarly S will also generate the same n dimensional subspace as S . So, let us consider the statement of this theorem. So, statement of theorem goes like this that. Let V be an inner product space and S is given as w_1, \dots, w_n be a linearly independent subset of V . So, it means that S is a linearly independent subset given here. So, it means that S generate a n dimension vector subspace of V .

Now, we want to define S as v_1, \dots, v_n where v_1 is nothing, but w_1 and v_k 's are given as $w_k - \sum_{j=1}^{k-1} \langle w_k, v_j \rangle v_j$ divided by norm of v_j square into v_j for all k from 2 to n . So, it means that if we define your v_i 's like this, then this S is an orthogonal set of nonzero vectors such that span of S is same as span of S and once we have a set of orthogonal set of orthogonal vectors, then we can divide by norm of each norm of respective quantity and we can make this S set of orthonormal vectors.

So, the idea behind this theorem is this that.

(Refer Slide Time: 04:04)

Suppose we have 2 vector say call it w_1 and say w_2 here, right. So, here w_1 and w_2 both are vectors int say \mathbb{R}^n or \mathbb{R}^m whatever the space is then we have define what is inner product of $w_1 w_2$ that we know how to define it depending on the coordinates here. So, if w_i suppose we can write it w_1 w_1 as say a_1 to say a_n and w_2 as b_1 to say b_n then inner product of $w_1 w_2$ is given as $a_i b_i$; i is equal to 1 to n .

Now, we have define the concept orthogonality is that w_1 is orthogonal to w_2 , if is this inner product is coming out to be 0. So, what is exactly meaning of this orthogonal orthogonality of w_1 and w_2 that with the help of this inner product, we can define the notion of angle.

So, it means that whenever we say that w_1 is orthogonal to w_2 , it means that the angle between w_1 and w_2 is 90 degree or we can say that w_1 is perpendicular to w_2 . So, if we can represent w_1 on. So, here since our physical constraint allow us to represent only elements of \mathbb{R}^2 . So, here let us consider this that w_1 and w_2 element of \mathbb{R}^2 . So, this represents some $a_1 a_2$ and this represents some b_1 and b_2 . So, these 2 represent 2 vectors here and if this angle θ which we denote if this angle is a 90 degree, then we say that w_1 is orthogonal to w_2 .

So, now that is what is what we mean by orthogonal orthogonality of w_1 and w_2 . So, now, we how to obtain a new set of vectors from w_1 and w_2 as v_1 and v_2 that is the content of theorem that we need to find out; out of these $w_1 w_2$ it is already given that

it is a LI set what we want to know is we want to find out a new set of vectors say v_1 and v_2 such that v_1 is orthogonal to v_2 v_1 is orthogonal to v_2 and a span of your this call it this S and call this as S' . So, span of S is same as span of S' .

So, for this, we always take v_1 as w_1 . So, the first factor is written as it is, we want to find out v_2 as linear combination of w_1 and w_2 in a way that this v_2 is orthogonal to v_1 . Now how to find out this thing, then if you look at here v_1 is nothing, but w_1 . So, it means that if you look at w_2 here, then w_1 is same as v_1 , then we want to look at this w_2 , then w_2 can be written as some same c of w_1 , right some vector here and a vector which is orthogonal to this and we say that whatever we obtained is nothing, but your v_2 . So, v_2 .

So, w_2 can be written as $c w_1$ plus w_2 and v_2 is something having angle 90 degree with w_1 or we can say 90 degree with vector v_1 here. So, we want to find out the $c w_1$ that if we know this $c w_1$ and we did we subtract this $c w_1$ from w_2 , we can get our v_2 . So, it means that our v_2 is going to be w_2 minus component along this vector w_1 . So, it means that in w_2 if we reduce the component which is along w_1 then we will have only component which is perpendicular to w_1 . So, that is the concept of this orthogonalization process.

So, we want to find out this c such that this v_2 is orthogonal to this v_1 . So, how to find out this c let us see. So, here what we have shown here that w_2 can be written as $c w_1$ plus v_2 and you want to find out this v_2 which is perpendicular to this v_1 or we can say perpendicular to w_1 . So, we want to find out contribution of w_2 along w_1 . So, we want to find out this c says that v_2 and v_1 are orthogonal to each other.

(Refer Slide Time: 09:30)

So, consider v_2 with v_1 which is nothing, but w_2 minus $c w_1$ with v_1 which is nothing, but w_1 . So, this is written as inner product w_2 with w_1 minus c inner product of w_1 with w_1 here and this is going to be 0 because we want that v_2 is orthogonal to v_1 . So, this is going to be 0. So, this implies that here c is going to be inner product of w_2 with w_1 divided by inner product of w_1 with w_1 . So, this is nothing, but norm of w_1 square. So, we can write it c as inner product of w_2 with w_1 divided by norm of w_1 square. So, this is your c . So, it means that if v_1 is equal to w_1 , then v_2 , you can define as w_2 minus c means w_2 inner product with w_1 divided by norm of w_1 square with w_1 .

So, it is the process when we consider for 2 vectors. So, what we have done here we have subtracted the component from w_2 which is along the vector w_1 . So, it means that now this v_2 will have no component along w_1 , it means that the component left in as v_2 as perpendicular to v_1 . So, angle between v_1 and v_2 is going to be 90 here. So, we are simply subtracting the part which is along the vector w_1 that is all.

So, that is how we are going to prove this theorem now regarding this span thing that the span of w_1 and w_2 is same as span of v_1 and v_2 . So, you can say that span of w_1 and w_2 is basically what span of w_1 I can write at write as v_1 . Now w_2 ; how we can write it w_2 we can write it as v_2 plus $c w_1$. So, we can write it v_2 plus $c w_1$. Now w_1 is nothing, but v_1 .

So, it means that span of w_1 and w_2 is nothing, but a span of v_1 comma v_2 plus $c v_1$. Now this is same as writing a span of v_1 and v_2 . So, it means that by this process, there is no change in a span. So, it means that a span of original set is same as span of the new obtained set. So, it means that a spanning set is having no problem. So, it means span of S dash is same as span of S .

So, let us consider the proof of this theorem.

(Refer Slide Time: 12:28)

Proof. The proof is by mathematical induction.
 For $k = 1, 2, \dots, n$, let $S_k = \{w_1, w_2, \dots, w_k\}$. If $n = 1$, then the theorem is proved by taking $S_1 = S'_1$; i.e., $v_1 = w_1 \neq 0$.
 Assume then that the set $S'_{k-1} = \{v_1, v_2, \dots, v_{k-1}\}$ with the desired properties has been constructed by the repeated use of (2). We show that the set $S'_k = \{v_1, v_2, \dots, v_{k-1}, v_k\}$ also has the desired properties, where v_k is obtained from S'_{k-1} by (2).
 If $v_k = 0$ then (2) implies that $w_k \in \text{span}(S'_{k-1}) = \text{span}(S_{k-1})$, which contradicts the assumption that S_k is linearly independent.

And this proof is can be done by mathematical induction. Now induction we are running over the number of vectors available on in a given set S . So, let us say for k equal to 1 to n let S_k is define as w_1 to w_k . So, for you take k equal to one then S_1 is defined as w_1 if you take k equal to n your S_n is defined as w_1 to w_n which is your set S now if n equal to one then this theorem is trivially true because for k equal to one S_1 is w_1 . So, S_1 is w_1 . So, your S dash is again same as w_1 . So, here S_1 is same as S_1 dash and a span of S_1 is same as span of S_1 dash. So, it means that our theorem is done for n equal to one.

Now, we assume that this theorem is true for n equal to k minus one. So, assume then that the set S_{k-1} dash equal to v_1 to v_{k-1} with the desired property has been constructed by the repeated use of two. So, it means if you follow and the procedure given here and for k equal to one we have already seen for up to k minus 1 we have already constructed we want to show that for k plus one it is also true. So, we want

to show that the set S_k which is consisting v_1 to v_{k-1} comma v_k also has a desired property. So, we have assumed that for n equal to $k-1$ theorem is true we want to show for n equal to k theorem is prove theorem is true. So, we want to show that S_k has the desired property.

Now, let us say that this v_k is 0 or not. So, if $v_k = 0$, then this S_k is linearly dependent and this is not going to be an orthogonal set. So, first we want to avoid the possibility that v_k is a never 0. So, if $v_k \neq 0$, then look at your equation number 2 if v_k is 0, then w_k can be written as linear combination of w_j j equal to 1 to $k-1$. So, inner product of w_k with v_j divided by norm of v_j square and v_j .

Now, so, it means that w_k can be written as linear combination of v_j 's. So, it means that w_k belongs to span of v_j j is from one to $k-1$. Now we already know that for $k-1$ a span of S_{k-1} is same as a span of S_k . So, it means that w_k belongs to span of w_1 to w_{k-1} which is a contradiction because we have already assumed that S is a linearly independent subset of v . So, it means that w_k cannot be written as a linear combination of w_1 to w_{k-1} . So, it means that w_k cannot be written as linear combination of v_1 to v_{k-1} .

So, it means that this vector v_k is never going to be 0. So, it means that if v_k is equal to 0, then equation implies that w_k belongs to a span of S_{k-1} which is same as a span of S_{k-1} which is the assumption we have already made that for n equal to $k-1$ where the theorem is true. So, w_k belongs to a span of S_{k-1} which is a contradiction because we have w_i 's are linearly independent set of vectors. So, it means that v_k is never 0.

(Refer Slide Time: 16:18)

For, $1 < i < k - 1$, it follows from (2) that

$$\langle v_k, v_i \rangle = \langle w_k, v_i \rangle - \sum_{j=1}^{k-1} \frac{\langle w_k, v_j \rangle}{\|v_j\|^2} \langle v_j, v_i \rangle = \langle w_k, v_i \rangle - \frac{\langle w_k, v_i \rangle}{\|v_i\|^2} \|v_i\|^2.$$

Since $\langle v_i, v_j \rangle = 0$ if $i \neq j$ by the assumption that S'_{k-1} is orthogonal. Hence S'_k is an orthogonal set of nonzero vectors. Now, by (2), we have that $\text{span}(S'_k) \subseteq \text{span}(S_k)$. Since, S'_k is linearly independent; so $\dim(\text{span}(S_k)) = \dim(\text{span}(S'_k)) = k$. Therefore, $\text{span}(S_k) = \text{span}(S'_k)$.

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 14

So, if v_k is non zero, then take the inner product of this v_k with v_i where i is running from 1 to $k - 1$, what we want to show here that this v_k is orthogonal to v_i 's i from 1 to $k - 1$.

So, to show that let us find out say inner product this and v_k is written as $w_k - \sum_{j=1}^{k-1} \frac{\langle w_k, v_j \rangle}{\|v_j\|^2} v_j$. So, when you perform the inner product it is what inner product of w_k with v_i minus here we have taken the help of properties of inner product and we can write it like this. So, let us look at here.

(Refer Slide Time: 17:13)

$$u_k = w_k - \sum_{j=1}^{k-1} \frac{\langle w_k, u_j \rangle}{\langle u_j, u_j \rangle} u_j$$

$$1 \leq i \leq k-1$$

$$\langle u_k, u_i \rangle = \left\langle w_k - \sum_{j=1}^{k-1} \frac{\langle w_k, u_j \rangle}{\|u_j\|^2} u_j, u_i \right\rangle$$

$$= \langle w_k, u_i \rangle - \sum_{j=1}^{k-1} \frac{\langle w_k, u_j \rangle}{\|u_j\|^2} \langle u_j, u_i \rangle$$

$$= \langle w_k, u_i \rangle - \langle w_k, u_i \rangle = 0$$

$$S_k' = \{u_1, \dots, u_k\}$$

$$\text{Span}(S_k') = \text{Span}(S_k)$$

$$\text{Span}(S_{k-1}') = \text{Span}(S_{k-1})$$

$$u_k \in \text{Span}(S_{k-1} \cup \{w_k\})$$

$$u_k \in \text{Span}\{w_k, u_1, \dots, u_{k-1}\}$$

$$\in \text{Span}\{w_k, u_1, \dots, u_{k-1}\}$$

$$= \text{Span}(S_k)$$

$$\text{Span}(S_k') \subseteq \text{Span}(S_k)$$

So, we have assumed that theorem is true for n equal to k minus 1 and we want to prove for theorem for n equal to k . So, it means that we want to show that S dash which is v_1 to v_k is an orthogonal set of vectors and span of S dash is same as span of S here where S is given by say w_1 to say w_k and we already know that for theorem is true for n equal to k minus one. So, here let us use the notation here which we have defined here this k represent the number of element and the corresponding set.

So, here we have defined v_k as this v_k as w_k minus j equal to one to k minus 1 inner product of w_k with v_j divided by inner product of v_j with v_j in to v_j . So, this is nothing, but norm of v_j square. So, now, take the inner product of v_k with v_i where i is from one to k minus 1 with the help of this we want to show that this set S_k dash is an orthogonal set. So, for that taking the inner product here this v_k you can utilize this expression here.

So, it is nothing, but an v_k , we are writing this. So, w_k minus j equal to one to k minus 1 v_j with inner product of w_k with v_j divided by norm of v_j square into v_j comma v_i . Now here we use the property of inner product. So, this can be written as inner product of w_k with v_i . So, here we are taking inner product with this and this and minus this remaining element summation j equal to one to k minus 1 w_k v_j divided by norm of v_j square that we can take out because this is nothing, but constant term. So, this we can take out take out and we have left is inner product of v_j with v_i .

So, here now j is from one to $k - 1$ and i is also from one to $k - 1$. So, it means that both v_j and v_i are elements of S_{k-1} . So, here these are elements of S_{k-1} and there we already know that S_{k-1} is an orthogonal set of vectors. So, it means that these v_j 's and v_i 's where i and j is running from one to $k - 1$ are orthogonal to each other.

So, it means that they will be this will be nonzero only when j is equal to i for all other things it is going to be 0. So, this implies that this is nothing, but w_k with the v_i minus only j equal to i is left. So, it means that for j equal to i it is what $w_k v_i$ divided by norm of v_i square and here what is left here inner product of v_i with v_i which is nothing, but norm of v_i square. So, that these 2 things are cancelled out because we already know that v_i 's are nonzero. So, we can cancel and if you look at this nothing, but $w_k v_i$ inner product of $w_k v_i$ minus inner product of $w_k v_i$ which is going to be 0.

So, it means that $v_k v_i$ is equal to 0. So, it means that this S_{k-1} to v_k is an orthogonal set. So, this we have proved that S_k is an orthogonal set now what is left here that span of S_k is equal to span of S_{k-1} , but we already know that span of S_k is equal to span of S_{k-1} union w_k which is which is trivially written here because if you look at v_k v_k is what v_k is written as w_k and linear combination of v_j 's.

Now, these v_j 's are coming from where v_j 's are coming from as span of S_{k-1} . So, it means that v_k can be written as span of w_k and your v_i 's and span of. So, it means that here we can say that by equation number this v_k belongs to the span of w_k and v_1 to v_{k-1} . Now this is what this belongs to span of. So, it means that this belongs to span of w_k and span of v_1 to v_{k-1} is nothing, but a span of w_1 to w_{k-1} . So, this means that this is nothing, but a span of this is nothing, but a span of S_k . So, it means that v_k belongs to a span of S_k . So, it means that your span of S_{k-1} is already in span of S_k . So, this is also belongs to. So, which means that span of S_k is containing a span of S_k , right. Now we already know that both has the dimension k because it is linearly independent. So, the span set has a dimension k vectors subspace which is generate is having dimension k . Similarly this is an orthonormal orthogonal set of vectors. So, it is also linearly independent. So, the dimension of vector subspace which is which it generate is also having dimension k .

So, it means that that dimension of span of S is same as dimension of span of S which is nothing, but k . So, it means that here not only containment is true, but equality is true. So, it means that span of S is same as span of S . So, it means that with the help of this process we are able to find out from a given linearly independent set we can find out a orthogonal set out of it. So, take the certain example of this process and let us see.

So, first example is that in \mathbb{R}^4 let S having these 3 vectors w_1 to w_3 where w_1 is given as $(1, 0, 1, 0)$ w_2 is $(1, 1, 1, 1)$.

(Refer Slide Time: 23:55)

Example. In \mathbb{R}^4 , let $S := \{w_1, w_2, w_3\}$, where $w_1 = (1, 0, 1, 0)$, $w_2 = (1, 1, 1, 1)$ and $w_3 = (0, 1, 2, 1)$. Find the orthonormal set S' such that $\text{Span}(S) = \text{Span}(S')$.

Solution. Since $S = \{w_1, w_2, w_3\}$ is a linearly independent. So, first we use the Gram Schmidt process to compute the orthogonal vectors v_1, v_2 and v_3 and then we can normalize these vectors to obtain S' .

Take $v_1 = w_1 = (1, 0, 1, 0)$. For v_2 , we have

$$\begin{aligned} v_2 &= w_2 - \frac{\langle w_2, v_1 \rangle}{\|v_1\|^2} v_1 \\ &= (1, 1, 1, 1) - \frac{2}{2}(1, 0, 1, 0) \\ &= (0, 1, 0, 1). \end{aligned}$$

Now,

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

And w_3 as $(0, 1, 2, 1)$. So, here S is a given set we want to find out another set orthonormal set is this says that a span of S is same as the span of S . So, here we want to use Gram Schmidt orthogonalization process to find out this orthonormal set S . So, here if you look at this set S consisting these 3 element w_1, w_2, w_3 and we can easily check that these w_i 's are a linearly independent vectors. So, it means that S is given as a linearly independent set. So, it means that we can apply our gram Schmidt orthogonalization process to find out this S . So, first we try to find out orthogonal set and then we are normalize a to find out S .

So, let us find out v_i 's means v_i 's are set of orthogonal vectors. So, v_1 as it is as w_1 . So, v_1 we can take as w_1 . So, v_1 is nothing, but $(1, 0, 1, 0)$ to find out the second vector v_2 , we start with w_2 and take the part of w_2 which is in the

direction of w_1 . So, it means that w_1 is same as v_1 . So, it means that we take out the component of w_2 which is in this direction of v_1 .

So, that we have shown that it is nothing, but inner product of w_2 with v_1 divided by norm of v_1 square. So, it calculate this inner product w_2 with v_1 . So, if you look at w_2 is this v_1 is same as w_1 . So, inner product of w_2 and w_1 is basically component wise. So, w_2 inner product w_1 is going to be 1 into 1 plus 1 into 0 plus 1 into 1 plus 1 into 0 . So, it is going to be 2 here. So, inner product of w_2 with v_1 is going to be 2 .

Now, looking at the norm of v_1 square; so, norm of v_1 is square basically what inner product of v_1 with v_1 itself. So, that is going to be 1 into 1 plus 0 into 0 plus 1 into 1 plus 0 into 0 . So, again it is coming out to be 2 here. So, this is 2 , this is 2 . So, you can say that these 2 will cancel out and v_1 is given at 1 comma 0 comma 1 comma 0 . So, here we can subtract this term, this component along w_1 from w_1 . So, if you subtract this is nothing, but 0 comma 1 comma 0 comma 1 .

(Refer Slide Time: 26:46)

The slide contains the following mathematical derivation and text:

$$v_3 = w_3 - \frac{\langle w_3, v_1 \rangle}{\|v_1\|^2} v_1 - \frac{\langle w_3, v_2 \rangle}{\|v_2\|^2} v_2$$

$$= (0, 1, 2, 1) - \frac{2}{2}(1, 0, 1, 0) - \frac{2}{2}(0, 1, 0, 1)$$

$$= (-1, 0, 1, 0).$$

These vectors can be normalized to obtain the orthonormal set $S' = \{u_1, u_2, u_3\}$, where

$$u_1 = \frac{1}{\|v_1\|} v_1 = \frac{1}{\sqrt{2}}(1, 0, 1, 0)$$

$$u_2 = \frac{1}{\|v_2\|} v_2 = \frac{1}{\sqrt{2}}(0, 1, 0, 1)$$

$$u_3 = \frac{1}{\|v_3\|} v_3 = \frac{1}{\sqrt{2}}(-1, 0, 1, 0)$$

At the bottom of the slide, there are logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, and the page number 16.

So, v_2 is coming out to be this vector 0 comma 1 comma 0 comma 1 . Now to find out v_3 from w_3 , v_2 find out v_3 , we have to take out the component of w_3 along v_1 and v_2 . So, component of w_3 along v_1 is given by inner product of w_3 with v_1 divided by norm of v_1 square and component of w_3 along v_2 is what inner product of w_3 with v_2 divided by norm of v_2 square.

So, we have to calculate these constants and then we are done. So, w_3 is given by $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$ and inner product of w_3 with v_1 is basically what w_3 with v_1 is basically what $0 \cdot 0 + 1 \cdot 1 + 1 \cdot 1 = 2$. So, it is coming out to be 2 here. So, that is written here and norm of v_1 is square, we have already calculated is coming out to be 2 and v_1 is $\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$. Similarly, we can calculate the inner product of w_3 with v_2 , I am not going to calculate, you may calculate because w_3 is given here and v_2 is given by this. So, you can calculate the inner product of w_3 with v_2 and it is also coming out to be 2 and norm of v_2 is coming out to be 2.

So, if you simplify it is coming out to be v_3 as $\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}$. So, with this, we are done with Gram Schmidt orthogonalization process and now from in place of w_1, w_2, w_3 , we have v_1, v_2 and v_3 as set of orthogonal vectors now to find out orthonormal set, we want we have to normalize these vectors. So, it means that we have u_1, u_2, u_3 and these are orthonormal set of vectors.

So, u_1 can be obtained as v_1 divided by norm of v_1 u_2 can be obtained as v_2 divided by norm of v_2 and u_3 as v_3 divided by norm of v_3 . So, v_1 is given by $\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$ and norm of v_1 is what inner product of v_1 with v_1 power half. So, inner product norm of v_1 square is coming out to be 2. So, norm of v_1 is coming out to be under root of 2.

So, u_1 is given as $\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$. Similarly u_2 is given as v_2 divided by norm of v_2 . So, norm of v_2 is again under root 2. So, this can be written as u_2 . So, u_3 is norm of v_3 and you can easily calculate in norm of v_3 as nothing, but under root 2 also; so, u_1, u_2, u_3 given as these vectors. So, now, we have as S given as $\{u_1, u_2, u_3\}$ as set of a set of orthonormal vectors. So, that we have obtained from they set S . So, w_1, w_2, w_3 are simple linearly independent set and what we have achieved here is a new set S where vectors u_1, u_2, u_3 are orthonormal set of vectors.

(Refer Slide Time: 29:58)

Example. Let $V = P(\mathbb{R})$ with the inner product $\langle f(x), g(x) \rangle = \int_{-1}^1 f(t)g(t)dt$. Consider the subspace $W := P_2(\mathbb{R})$ with the standard ordered basis $S = \{1, x, x^2\}$. Find the orthonormal basis S' for W .

Solution. We can use the Gram Schmidt process to replace S by an orthogonal basis $S' := \{v_1, v_2, v_3\}$ for $P_2(\mathbb{R})$, and then use this orthogonal basis to obtain an orthonormal basis for $P_2(\mathbb{R})$.

Take $v_1 = 1$. Then $\|v_1\|^2 = \int_{-1}^1 1^2 dt = 2$, and $\langle x, v_1 \rangle = \int_{-1}^1 t \cdot 1 dt = 0$. Thus

$$v_2 = x - \frac{\langle v_1, x \rangle}{\|v_1\|^2} = x - \frac{0}{2} = x$$

Furthermore

$$\langle x^2, v_1 \rangle = \int_{-1}^1 t^2 dt = \frac{2}{3}.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 17

Now, moving on next example we have a vector space which is a set of all polynomials with inner product this inner product of $f(x)$ with $g(x)$ is given as $\int_{-1}^1 f(t)g(t)dt$. So, this is the inner product defined on this inner product and we want to find out say the standard order basis sorry, orthonormal basis S' for W where W is $P_2(\mathbb{R})$ set of all polynomials whose degree is at most 2 and what is given here it is given that we have a standard order basis $1, x, x^2$. So, it means that having this vector subspace which is given as $P_2(\mathbb{R})$ we have a standard order basis we want to find out a orthonormal basis for this W .

So, for this also we can use Gram Schmidt orthogonalization process. So, we want to replace this ortho standard order basis by an orthogonal basis as v_1, v_2, v_3 we want to find out what is v_1, v_2, v_3 . So, for that; we take v_1 as one and if you look at the norm of v_1 square. So, norm of v_1 square is going to be inner product of v_1 with v_1 itself. So, that is in inner product definition of inner product is given here. So, inner product of v_1 with v_1 is basically $\int_{-1}^1 1 \cdot 1 dt = 2$. So, simply it is $\int_{-1}^1 1^2 dt = 2$. So, we have norm of v_1 square as 2.

Now, to find out v_2 , we subtract from x the component along v_1 . So, v_1 is one here. So, we subtract the component of x along 1. So, x minus inner component of x along one which is given as inner product of v_1 with x divided by norm of v_1 square. So, inner product v_1 with x is given by this it is what $\int_{-1}^1 t \cdot 1 dt = 0$, now here I am

using in the integration variable as t. So, this is nothing, but minus 1 to 1 t into 1 d t. Now if you look at this can be written as 0; so, value of this integral is coming out to be 0; so, it means that a x has no component along one. So, it means that x is already orthogonal to 1 with this inner product. So, it means that v 2 can be written as x itself. So, v 1 is given by one and v 2 is given by x.

Now, to find out v 3 we need to subtract the component of x square along one and x. So, for that we need to find out say inner product of x square with x and inner product of x square with one. So, let us find out say inner product of x square with v one. So, it is given by minus 1 to 1 x square we can write it t square v 1 is one here. So, t square d t and if you simplify this is nothing, but t cube by 3 limit is from minus 1 to one. So, it is given by 2 by 3. So, inner product of x square with v 1 is coming out to be 2 by 3.

(Refer Slide Time: 33:21)

and

$$\langle x^2, v_2 \rangle = \int_{-1}^1 t^2 \cdot t dt = 0$$

Therefore

$$v_3 = x^2 - \frac{\langle x^2, v_2 \rangle}{\|v_2\|^2} v_2 - \frac{\langle x^2, v_1 \rangle}{\|v_1\|^2} v_1$$

$$= x^2 - \frac{1}{3} \cdot 1 - 0 \cdot x$$

$$= x^2 - \frac{1}{3}$$

Hence, we conclude that $\{1, x, x^2 - \frac{1}{3}\}$ is an orthogonal basis for $P_2(\mathbb{R})$ and from here, we can easily show that $\{\frac{1}{\sqrt{2}}, \frac{\sqrt{3}}{2}x, \frac{\sqrt{5}}{8}(3x^2 - 1)\}$ is an orthonormal basis for $P_2(\mathbb{R})$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 18

Similarly, we want to find out inner product of x square with v 2 and here v 2 is nothing, but x here. So, that is minus 1 to 1 t square into t d t if you simplify this is coming out to be 0 why because we can use simple property of integral. So, that it is odd function and limit is minus a to a. So, that can be shown that it is nothing, but 0.

So, to find out v 3 v 3 as x square minus component of x square along v 2 and component of x square along v one. So, that we have already calculated x square v 2 is nothing, but 0. So, it means that x square has no component along v 2 and then x square

a component of x square along v_1 which we have already calculated $\frac{2}{3}$ and norm of v_1 square we have seen as 2 here.

So, using this, this is 0 . no component $0 \cdot x$ and this as $\frac{2}{3}$ divided by 2 . So, it is $\frac{1}{3}$ into 1 . So, here v_3 is coming out to be x square minus $\frac{1}{3}$. So, it means that we have this $1, x, x^2 - \frac{1}{3}$ as an orthogonal basis for $P_2 \mathbb{R}$ and from this, we can find out say orthonormal basis how we can find out the orthonormal basis we have to divide by norm of the respective vectors. So, norm of one with the help of this inner product minus 1 to 1 f t g t d t we have shown that norm of v_1 is coming out to be 2 .

So, we divide by norm norm of v_1 . So, sorry norm of v_1 is going to be $\frac{1}{\sqrt{2}}$ upon norm of v_1 is one a norm of v_1 is going to be under root two. So, one divided by root 2 is an orthonormal vector. Similarly norm of x we can find out. So, it is coming out to be $\frac{2}{\sqrt{3}}$. So, we can say that x divided by under root 2 by 3 is root 3 by $2x$. Similarly, we can find out say norm of $x^2 - \frac{1}{3}$ and we can say that under root 5 by 8 $3x^2 - \frac{1}{3}$ is the new orthonormal vector. So, it means that this set one by root 2 comma under root 3 by $2x$ comma under root 5 by 8 $3x^2 - \frac{1}{3}$ is an orthonormal basis for $P_2 \mathbb{R}$.

So, that complete the proof that complete the solution of this just one thing since we have calculated the norm of v_1 as this, but we have not calculated the norm of v_2 . So, let us just I just want to show that now how to calculate the norm of v_2 and then I will finish because if you know; how to find out the norm of v_2 , you can use a same technique to find out say norm of v_3 and that will complete that job.

(Refer Slide Time: 36:26)

$$\begin{aligned}\|x\|^2 &= \langle x, x \rangle = \int_{-1}^1 t \cdot t \, dt \\ &= \int_{-1}^1 t^2 \, dt = \frac{2}{3} \\ \|v_2\| &= \|x\| = \sqrt{\frac{2}{3}} \\ \frac{x}{\sqrt{\frac{2}{3}}} &\Rightarrow \sqrt{\frac{3}{2}} x\end{aligned}$$

So, first we need to find out say norm of x . So, norm of x square we know that it is nothing, but inner product of x with x and it is nothing, but minus 1 to 1 $f t$ means t , here and again t and $d t$. So, this is what it is t square minus 1 to 1 $d t$ and it is coming out to be $\frac{2}{3}$. So, it is t cube basically t cube and minus 1 to 1. So, this is the norm of x square. So, we can say that norm of v_2 is going to be under root norm of x here which is given as $\sqrt{\frac{2}{3}}$. So, it means that we have x divided by under root $\frac{2}{3}$.

So, it means that this is nothing, but under root $\frac{3}{2}$ x is going to be an orthonormal vector here. So, that is what is written here under root $\frac{3}{2}$ x is the orthonormalization of x here similarly you can find out say norm of v_3 that is x square minus 1 by 3 and this coming out to be under root this $\frac{8}{5}$. So, we can find out a orthonormal basis out of this $P^2 R$.

So, here we conclude our lecture here. So, what we have learnt from this lecture that given a LI set, we started with LI set say let us say S is you know we have v_1 to some v_n it is a LI set.

(Refer Slide Time: 38:04)

So, from this set, we are able to find out a new set S' say u_1 to u_n says that this S' is an orthogonal set right and a span of S' is same as span of S . So, it means that by this process there is no change in span. So, it means that if this represents a basis, then this will also represent a basis. So, here if S is a basis, then S' is an orthogonal basis for the same vector subspace. So, here we just have wind up and we will meet in next lecture.

Thank you very much.
