Lecture - 23
Error propagation in computer arithmetic

Hello friends, welcome to my lecture on Error Propagation in computer arithmetic.

(Refer Slide Time: 00:24)

Error Propagation in Computer Arithmetic:

Since most real numbers can not be exactly represented in computers, there are round-off errors (chopping and rounding errors) for each such machine representation. Hence, arithmetic operations performed in the computer cause significant round-off errors due to the propagation of the errors. Let us discuss the errors associated with each of the four basic arithmetic operations e.g. addition, subtraction, multiplication and division, performed in the computer.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 2

Since most real numbers cannot be exactly represented in computers, there are round off errors which are caused due to chopping and rounding errors; for each such machine representation. Hence arithmetic operations performed in the computer cause significant round off errors due to the propagation of the errors.

Let us discuss the errors associated with each of the four basic arithmetic operations namely addition, subtraction, multiplication and division which are performed, in the computer.

(Refer Slide Time: 00:57)

Let $f_l(x) = x(1 + \varepsilon_x)$ and $f_l(y) = y(1 + \varepsilon_y)$, where $|\varepsilon_x| \leq \mu$ and $|\varepsilon_y| \leq \mu$.
Let us assume that ε_x and ε_y are so small that the second and higher order terms involving ε_x and ε_y may be neglected.

Multiplication: Let $f_l(xy) = xy(1 + \varepsilon)$.

Then $f_l(xy) = f_l(x)f_l(y) = x(1 + \varepsilon_x)y(1 + \varepsilon_y) \approx xy(1 + \varepsilon_x + \varepsilon_y)$ neglecting $\varepsilon_x\varepsilon_y$. Hence $\varepsilon = \varepsilon_x + \varepsilon_y$. \Rightarrow The relative error in the product is approximately the sum of the relative errors in the data. Hence, for small relative errors in the data, the relative error in the product is also small and so the error propagation in the multiplication operation is acceptable.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 3

Let us say the floating point representation of x we denote by $f_l x$ so, let $f_l x$ be equal to x into 1 plus ε_x and $f_l y$ equal to y into 1 plus ε_y .

(Refer Slide Time: 01:13)

$f_l(x) = x(1 + \varepsilon_x)$
and $f_l(y) = y(1 + \varepsilon_y)$
where $|\varepsilon_x| \leq \mu, |\varepsilon_y| \leq \mu$

$f_l(xy) = xy(1 + \varepsilon)$
 $f_l(xy) = f_l(x)f_l(y)$
 $= xy(1 + \varepsilon_x)(1 + \varepsilon_y)$
 $= xy(1 + \varepsilon_x + \varepsilon_y + \varepsilon_x\varepsilon_y)$
 $\approx xy(1 + \varepsilon_x + \varepsilon_y)$

Since $f_l(xy) = xy(1 + \varepsilon)$
 $\approx xy(1 + \varepsilon_x + \varepsilon_y)$

Then $\varepsilon \approx \varepsilon_x + \varepsilon_y$

Here $\varepsilon = \frac{f_l(xy) - xy}{xy}$

So, $f_l x$ equal to x into 1 plus ε_x and $f_l y$ equal to y into 1 plus ε_y where ε_x and ε_y are less than or equal to μ ; the machine precision μ denotes the machine precision. So, we further we assume that ε_x and ε_y are so small that their second and higher order terms involving ε_x and ε_y may be neglected. Let us first consider the case of multiplication so, in multiplication let us say

we have two numbers x and y ; the floating point representation of x into y will then be written as x into 1 plus ϵ .

So, $f_l x y$ we can write as x into 1 plus ϵ then because $f_l x y$ is equal to $f_l x$ into $f_l y$, let us put the values of $f_l x$ and $f_l y$, we shall get $f_l x y$ equal to x into 1 plus ϵ x $f_l x y$ equal to $f_l x$ into $f_l y$. So, substituting the values of $f_l x$ and $f_l y$ what we get; x into 1 plus ϵ x into 1 plus ϵ y . Let us multiply a 1 plus ϵ x and 1 plus ϵ y what we get? 1 plus ϵ x plus ϵ y plus ϵ x into ϵ y . Now, we have assumed that ϵ x and ϵ y are so, small that the terms of second and higher order terms involving ϵ x and ϵ y may be neglected.

So, this is the second order term ϵ x into ϵ y so, let us neglect this cut on then we can say this is approximately x into 1 plus ϵ x plus ϵ y . And now, $f_l x y$ is equal to x into 1 plus ϵ . Since $f_l x y$ is equal to x into 1 plus ϵ and it is approximately 1 plus ϵ , it is x into y 1 plus ϵ x plus ϵ y . We can say that the error the ϵ is approximately equal to ϵ x plus ϵ y so, we have. So the relative error now we can say that what is ϵ ? ϵ is here $f_l x y$, here ϵ is equal to $f_l x y$ minus x y upon x y .

So, the relative error because of ϵ equal to ϵ x plus ϵ y ; we can say that the relative error in the product is approximately the sum of the relative errors in the data. ϵ x and ϵ y denote the relative errors in x and y . So, for the small relative errors in the data that is when ϵ x and ϵ y are small we can say that the relative error in the product is also small and therefore, the error propagation in the multiplication operation is acceptable.

(Refer Slide Time: 05:26)

Division: Let $f\left(\frac{x}{y}\right) = \frac{x}{y}(1 + \varepsilon)$.

Then $f\left(\frac{x}{y}\right) = \frac{f(x)}{f(y)} = \frac{x(1 + \varepsilon_x)}{y(1 + \varepsilon_y)} = \frac{x}{y}(1 + \varepsilon_x)(1 + \varepsilon_y)^{-1}$

$$= \frac{x}{y}(1 + \varepsilon_x)(1 - \varepsilon_y + \varepsilon_y^2 - \varepsilon_y^3 + \dots)$$

$$= \frac{x}{y}(1 + \varepsilon_x - \varepsilon_y - \varepsilon_x \varepsilon_y + \dots)$$

$$\approx \frac{x}{y}(1 + \varepsilon_x - \varepsilon_y).$$

4

(Refer Slide Time: 05:34)

Let $f\left(\frac{x}{y}\right) = \frac{x}{y}(1 + \varepsilon)$

Then $f\left(\frac{x}{y}\right) = \frac{f(x)}{f(y)} = \frac{x(1 + \varepsilon_x)}{y(1 + \varepsilon_y)}$

$$= \frac{x}{y}(1 + \varepsilon_x)(1 + \varepsilon_y)^{-1}$$

$$= \frac{x}{y}(1 + \varepsilon_x)(1 - \varepsilon_y + \varepsilon_y^2 - \dots)$$

$$= \frac{x}{y}(1 + \varepsilon_x - \varepsilon_y - \varepsilon_x \varepsilon_y + \dots)$$

$$\approx \frac{x}{y}(1 + \varepsilon_x - \varepsilon_y)$$

Thus,

$$\frac{x}{y}(1 + \varepsilon) \approx \frac{x}{y}(1 + \varepsilon_x - \varepsilon_y)$$

$$\Rightarrow \varepsilon = \varepsilon_x - \varepsilon_y$$

Let us now consider the case of division so, in division operation let us assume that let $f\left(\frac{x}{y}\right) = \frac{x}{y}(1 + \varepsilon)$ then $f\left(\frac{x}{y}\right) = \frac{f(x)}{f(y)} = \frac{x(1 + \varepsilon_x)}{y(1 + \varepsilon_y)}$ over $f\left(\frac{x}{y}\right)$ is equal to x into $1 + \varepsilon_x$ divided by y into $1 + \varepsilon_y$.

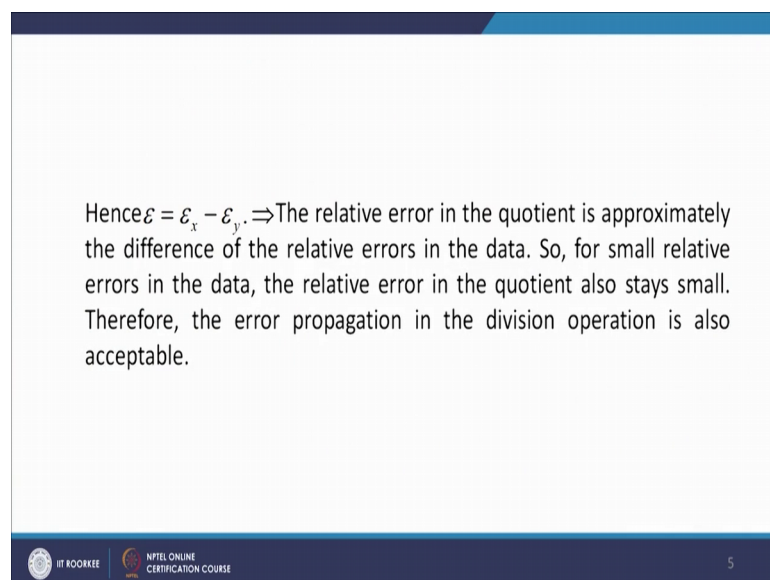

Now, since ε_x and ε_y are very small what we can do I can write it as $\frac{x}{y}(1 + \varepsilon_x)(1 + \varepsilon_y)^{-1}$. Since ε_y is very small mode of ε_y is less than 1 so, we can expand this $1 + \varepsilon_y$ to the

power minus 1 binomial expansion and we have x over y $1 + \epsilon_x$ into $1 - \epsilon_y$ plus $\epsilon_x \epsilon_y$ square and so, on.

Now, when we multiply this infinite series to $1 + \epsilon_x$ what we have $1 + \epsilon_x$ minus ϵ_y minus $\epsilon_x \epsilon_y$ plus $\epsilon_x \epsilon_y$ square plus ϵ_x ϵ_y square and so, on. Now, since the second order terms and higher order terms containing ϵ_x and ϵ_y are to be neglected this is approximately equal to x over y into $1 + \epsilon_x$ plus minus ϵ_y .

So, thus x over y into $1 + \epsilon_x$ is approximately x over y $1 + \epsilon_x$ minus ϵ_y and so, what we get is ϵ is equal to approximately ϵ_x minus ϵ_y and from this equation ϵ equal to ϵ_x minus ϵ_y .

(Refer Slide Time: 08:16)

Hence $\epsilon = \epsilon_x - \epsilon_y$. \Rightarrow The relative error in the quotient is approximately the difference of the relative errors in the data. So, for small relative errors in the data, the relative error in the quotient also stays small. Therefore, the error propagation in the division operation is also acceptable.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 5

We can conclude that the relative error in the quotient the relative error in the quotient ϵ is approximately the difference of the relative errors in the data, the difference of the relative error of x and the relative error of y and thus for small relative errors in the data that is when ϵ_x and ϵ_y are small the relative error in the quotient also stage small and so, the error propagation in the division operation is also acceptable.

Now, let us consider the case of addition and subtraction.

(Refer Slide Time: 09:11)

If x and y are of opposite sign & $|x| \approx |y|$
 $x - y = x + (-y)$
 Let $f(x+y) = (x+y)(1+\epsilon)$
 $f(x+y) = f(x) + f(y)$
 $= x(1+\epsilon_x) + y(1+\epsilon_y)$
 $= (x+y) \left(1 + \frac{x\epsilon_x + y\epsilon_y}{x+y} \right)$
 So, $(x+y)(1+\epsilon) = (x+y) \left(1 + \frac{x\epsilon_x + y\epsilon_y}{x+y} \right)$
 $\Rightarrow \epsilon = \frac{x\epsilon_x + y\epsilon_y}{x+y}$
 $= \frac{x}{x+y} \epsilon_x + \frac{y}{x+y} \epsilon_y$ ①
 If x & y are of same sign
 then $\left| \frac{x}{x+y} \right| < 1$
 and $\left| \frac{y}{x+y} \right| < 1$
 So $|\epsilon| < |\epsilon_x| + |\epsilon_y|$

So, first we observe that if we have two numbers x and y then x minus y can be regarded as x plus minus y and therefore, we can say that it is enough to consider the relative error in the sum of two numbers x minus y is sum of x and minus y .

So, just let us consider the relative error in the sum of two numbers let us assume that $f(x+y)$ is equal to $x+y$ into $1+\epsilon$, where ϵ is the relative error in the sum of x and y . So, then $f(x+y) = f(x) + f(y)$ gives $f(x+y) = f(x) + f(y)$ this is equal to $x(1+\epsilon_x) + y(1+\epsilon_y)$, what we get is $x+y$ if we take common we get $1 + \frac{x\epsilon_x + y\epsilon_y}{x+y}$ divided by $x+y$.

Now, $f(x+y) = (x+y)(1+\epsilon)$ so, $x+y$ into $1+\epsilon$ is equal to $x+y$ into $1 + \frac{x\epsilon_x + y\epsilon_y}{x+y}$ divided by $x+y$. From this equation we see that ϵ is equal to $\frac{x\epsilon_x + y\epsilon_y}{x+y}$ or we can write it as $\frac{x}{x+y} \epsilon_x + \frac{y}{x+y} \epsilon_y$.

(Refer Slide Time: 11:20)

Addition and Subtraction: Since $x - y = x + (-y)$. It is enough to consider the relative error in the sum of two numbers.

Let $fl(x + y) = (x + y)(1 + \varepsilon)$.

Since $fl(x + y) = fl(x) + fl(y)$

$$= x(1 + \varepsilon_x) + y(1 + \varepsilon_y)$$
$$= (x + y) \left(1 + \frac{x\varepsilon_x + y\varepsilon_y}{x + y} \right),$$

we obtain

$$\varepsilon = \frac{x\varepsilon_x + y\varepsilon_y}{x + y} = \left(\frac{x}{x + y} \right) \varepsilon_x + \left(\frac{y}{x + y} \right) \varepsilon_y \dots (1)$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 6

So, we get $\frac{x}{x + y}$ equal to $\frac{y}{x + y}$ and if we suppose that x and y have the same sign then mode of x over $x + y$ is strictly less than 1 and mode of y over $x + y$ is strictly less than 1 and therefore, mode of ε is less than mode of ε_x plus mode of ε_y .

(Refer Slide Time: 11:32)

Supposing x and y have the same sign then $\left| \frac{x}{x + y} \right| < 1$ and $\left| \frac{y}{x + y} \right| < 1$,
so $|\varepsilon| < |\varepsilon_x| + |\varepsilon_y|$.

Thus, if x and y have the same sign, then the relative error in the sum is bounded by the sum of the relative errors in the data. So, if the relative errors in the data are small, the relative error in the sum is also small. Thus, the error propagation in this case of addition is acceptable.

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE 7

So, if x and y of same sign then we can say that mode of x over $x + y$ is strictly less than 1 and mode of y over $x + y$ is strictly less than 1 and therefore, mode of ε is less than mode of ε_x plus mode of ε_y . Thus, if x and y have the same sign then the relative error in the sum is bounded by the sum of the

relative errors in x and y are small, if the relative error in the data are small that is ϵ_x and ϵ_y are small then we can see that the relative error in the sum of x and y is also small and so, the error propagation in this case of addition is also acceptable

(Refer Slide Time: 12:47)

However, if x and y are opposite in sign and $|x| \approx |y|$ then $\frac{x}{x+y}$ and $\frac{y}{x+y}$ will be quite large because $x+y$ is close to zero.

Hence from (1), the relative error ϵ will be large. So, the error propagation in this case is not acceptable. The large magnification of error in (1) is called the **cancellation error** and should be avoided as far as possible.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

Now, if x and y are of opposite sign let then what do we have, if x and y are of opposite sign and mode of x minus is approximately equal to mode of y and mode of x and mode of y are approximately equal then x over $x+y$ and y over $x+y$ will be quite large because $x+y$ will be very near to 0. So, x over $x+y$ and y over $x+y$ will be quite large because $x+y$ is close to 0 and hence from equation 1, this equation 1 this one this equation 1.

So, from equation 1 it follows that the relative error in the computation of ϵ is also large so, the relative ϵ will be large because ϵ is $\frac{x}{x+y}$ into ϵ_x plus $\frac{y}{x+y}$ into ϵ_y . So, when $\frac{x}{x+y}$ and $\frac{y}{x+y}$ are large relative error ϵ will be large so, the error propagation in this case is not acceptable. The large magnification of error in the equation 1 is called the cancellation error and should be avoided as far as possible.

Now, let us see some cases where we will see how we can avoid the cancellation error.

(Refer Slide Time: 14:30)

Example: Let us consider a machine with 5-digit decimal system with rounding i.e. with $\beta = 10$ and $t = 5$. Let $x = 12.9876$ and $y = -12.9873$.

Solution: Here x and y differ in sign and $|x| \approx |y|$. We have $fl(x) = 12.988$ and $fl(y) = -12.987$.

Hence $E_x = \frac{x - fl(x)}{x} \approx -3.08 \times 10^{-5}$ and $E_y = \frac{y - fl(y)}{y} \approx 2.31 \times 10^{-5}$ which are both very small and negligible.

The relative error in $x + y$ is $\varepsilon = \frac{x}{x+y} \varepsilon_x + \frac{y}{x+y} \varepsilon_y \approx -2.333$, which is not negligible.

Thus, it is an example of propagation of error due to the cancellation error.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So, let us consider the machine with 5 digit decimal system so, here we have t equal to 5 and β equal to 10, β tells us the base of the digital system and t tells us the number of significant digits that we have to retain.

(Refer Slide Time: 14:36)

$t = 5$
 $\beta = 10$

$x = 12.9876$
 $y = -12.9873$

$|x| \approx |y|$ $x = 0.129876 \times 10^2$

$fl(x) = 0.12988 \times 10^2$ $y = -0.129873 \times 10^2$
 $= 12.988$ $fl(y) = -0.12987 \times 10^2$
 $fl(y) = -12.987$ $= -12.987$

So, let us consider machine with 5 digit decimal system with rounding so, β is equal to 10 t equal to 5. Let us take x equal to 12.9876; x equal to 12.9876 and y equal to minus 12.9873 you can see that the x and y are of opposite sign and the absolute value of x is equal to 12.9876 absolute value of y is 12.9873 so, they are approximately same.

So, mode of x and mode of y are nearly equal now let us see when we find $f_l x$ the floating point representation of x so, for floating point representation of x we have to write it in the decimal system. So, x can be written as 12 ; x can be written as 0.129876 into 10 to the power 2 .

Now, we have to use rounding and we have to consider 5 significant digits so, $1, 2, 3, 4, 5$ since this $d_t + 1$ is 6 it is more than 5 we have to increase 7 by 1 unit and therefore, we shall have $f_l x$ equal to 0.12988 into 10 to the power 2 or we can say this is 12.988 . Similarly, y is equal to y can be written as minus 0.129873 into 10 to the power 2 and so, when we write floating point representation of y with t equal to 5 ; what we have minus 0 point now here $1, 2, 3, 4, 5$. So, $d_t + 1$ is 3 which is less than $\beta - 2$ that is 5 so, we keep this digit $d_t + 1$ as it we do not change so, 0.12987 into 10 to the power 2 or we get minus 12.987 . So, $f_l x$ is 12.988 $f_l y$ is minus 12.987 .

Now, we can calculate ϵ_x and ϵ_y ϵ_x is equal to $x - f_l x$ over x and it is minus 3.08 into 10 to the power minus 5 ϵ_y is $y - f_l y$ over y which is approximately 2.31 into 10 to the power minus 5 , you can see both are very small and so, can be assumed as negligible.

The relative error in $x + y$ which is given by ϵ_{x+y} equal to $x - f_l x$ over $x + y$ into $\epsilon_x + y - f_l y$ over $x + y$ into ϵ_y is approximately minus 2.333 which is not negligible as you can see it is minus 2.333 which is which cannot be neglected. Thus, it is an example of propagation of error due to the cancellation error x and y are of opposite sign the absolute values of x and y are nearly same ah.

So, when we calculate ϵ_x and ϵ_y the their values are very small, but still when we calculate ϵ_{x+y} which is the relative error in $x + y$ it turns out that it is not small it is not negligible. So, it is an example of propagation of error due to the cancellation error.

(Refer Slide Time: 19:08)

Now we illustrate how to avoid cancellation errors in numerical evaluation.

Example-1: Let $x > 0$. We know that $e^{-x} = 1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \dots$.

Here we can avoid the cancellation error by using the formula

$$e^{-x} = \frac{1}{e^x} = \frac{1}{1 + x + \frac{x^2}{2!} + \dots}$$

 IIT ROORKEE  NITEL ONLINE CERTIFICATION COURSE 10

Let us illustrate how to avoid cancellation errors in numerical evaluation for example, let us consider x to be greater than 0 we know that e^{-x} is $1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \dots$. So, if you want to calculate the value of e^{-x} for an x greater than 0 then you can see that there are negative positive terms alternately negative and positive terms.

So, there may there may there may be a situation where the two successive values are very close to each other so, and there will be an opposite sign in between the two. So, what we will do is here we can avoid the cancellation error by using the formula $e^{-x} = \frac{1}{e^x}$ because in e^x all terms will be positive when x is positive. So, there would there will not occur a situation where two successive terms are sums are nearly equal and they are opposite in sign.

So, we can to calculate e^{-x} we can use the formula $\frac{1}{e^x}$ which is $\frac{1}{1 + x + \frac{x^2}{2!} + \dots}$ and so, on and we can avoid the cancellation error.

(Refer Slide Time: 20:23)

Example-2: Let $y = \sqrt{x + \varepsilon} - \sqrt{x}$, $x > 0$ and ε is a very small real number.
Then, we may write $y = \frac{\varepsilon}{\sqrt{x + \varepsilon} + \sqrt{x}}$.

Example-3: Let $y = 1 - \cos x$, where x is a small real number close to zero.
Here we can use the formula $y = 2 \sin^2 \left(\frac{1}{2} x \right)$.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 11

Now, similarly let us take the case of an example of 2 which were y is equal to square root of x plus epsilon minus square root of x and x is positive.

(Refer Slide Time: 20:43)

So, here y is equal to since epsilon is very small is square root of x plus epsilon and square root of x are nearly equal and so, when we subtract the 2 there will be cancellation error.

So, to avoid the cancellation error what we do we write it as we multiply and divide by x square root of x plus epsilon plus square root of x then this is a minus b into a plus b. So,

we have a square minus b square so, we have $x + \epsilon - x$ divided by $\sqrt{2k}$ and this is equal to $\epsilon / \sqrt{2k}$.

Now, we have $\epsilon / \sqrt{2k}$ plus $\sqrt{2k}$ plus $\sqrt{2k}$ so, which are of which we are we have to find the sum of $\sqrt{2k}$ plus ϵ and $\sqrt{2k}$ and they are of same sign. So, the cancellation error can be avoided.

Now, another example we is there say y is equal to $1 - \cos x$ we have to calculate y equal to $1 - \cos x$ where x is given to be a small real number which close to 0 ok. So, when x is close to 0 $\cos x$ will be close to 1 it will be approximately one so, $1 - \cos x$ again we will have difference of 2 nearly equal numbers. So, what we do we can use the formula $y = 1 - \cos x = 2 \sin^2(x/2)$.

We know this formula from trigonometry $1 - \cos \theta = 2 \sin^2(\theta/2)$ so, $1 - \cos x$ is equal to $2 \sin^2(x/2)$ here we can easily find the value for x which is x is close to 0. So, we can easily find the value because there is no cancellation error involved here.

One more example let us take say $f(x) = e^x - e^{-2x}$ here again let us assume that we are we have to calculate $f(x)$ for values of x which are near 0 x is close to 0. So, when x is close to 0 e^x and e^{-2x} are both close to 1 so, we will have again a case of cancellation of cancellation error here. So, what we do is we can write it in alternate manner by writing this way $e^x - e^{-2x}$ we can take common so, $e^{-2x}(e^{3x} - 1)$ we have or we can write it this way e^{-2x} we write outside.

(Refer Slide Time: 24:27)

$$y = \sqrt{x+\epsilon} - \sqrt{x}, x > 0$$

$$= \frac{(\sqrt{x+\epsilon} - \sqrt{x})(\sqrt{x+\epsilon} + \sqrt{x})}{(\sqrt{x+\epsilon} + \sqrt{x})}$$

$$= \frac{(x+\epsilon) - x}{\sqrt{x+\epsilon} + \sqrt{x}} = \frac{\epsilon}{\sqrt{x+\epsilon} + \sqrt{x}}$$

$$y = 1 - \cos x$$

when x is close to zero,
 $\cos x \approx 1$

$$y = 1 - \cos x = 2 \sin^2 \frac{x}{2}, x \text{ is close to zero}$$

$$f(x) = e^{3x} - e^{2x}, x \text{ is close to zero } \& x > 0$$

$$= e^{2x}(e^{3x} - 1)$$

$$= \frac{e^{3x} - 1}{e^{2x}} = 1 + 3x + \frac{(3x)^2}{2!} + \dots - 1$$

Then this will be e to the power $3x - 1$ and this is equal to e to the power $3x - 1$ divided by e to the power $2x$, this will be equal to $1 + 3x - \frac{3x^2}{2!} + \dots$ and so, on minus 1 divided by e to the power $2x$ ok.

So, this 1 and this 1 cancel x is given to be a number x is close to 0 and greater than 0 x is greater than 0. So, what we will have here all terms will be of same sign and therefore, we can calculate the sum and this e to the power $2x$ also can be calculated there will be no cancellation error involved here. So, e to the power $2x$ minus e to the power x when x is close to 0 and is greater than 0 is an example of cancellation error, but the cancellation error can be avoided by writing this $f(x)$ function as e to the power $3x - 1$ over e to the power $2x$.

This 1 which is subtracted from e to the power $3x$ can be cancelled with the one occurring in e to the power $3x$ and then we see that all terms are of same sign because x is positive. So, there is no cancellation error in here and e to the power $2x$ is also positive for all x I mean will also contain all terms of the same sign. So, there will be no cancellation error involved here so, the cancellation error can be avoided by writing $f(x)$ as e to the power $3x - 1$ over e to the power $2x$, with that I would like to conclude my lecture.

Thank you very much for your attention.
