Lecture - 28
Stability of Numerical Algorithms- II

Hello friends I welcome you to my second lecture on stability of numerical algorithms. So, let us study some more examples to make the topic of stability of numerical algorithms clear.

(Refer Slide Time: 00:34)

Example: Let us consider the problem of calculating the numbers y_n from the formula

$$y_n = \int_0^1 x^n e^x dx \quad \dots\dots\dots(1)$$

Recurrence relation:
Using the integration by parts

$$y_{n+1} = e - (n+1)y_n \quad \dots\dots\dots(2)$$

From (1), we get

$$y_0 = e - 1$$

The slide includes logos for IIT Roorkee and NITEL Online Certification Course at the bottom.

Let us consider the problem of calculating the numbers y_n from the formula y_n equal to integral 0 to 1 $x^n e^x dx$.

(Refer Slide Time: 00:43)

First, we shall derive a recurrence relation from this formula, let us integrate by parts. So, we have $y_{n+1} = \int_0^1 x^{n+1} e^x dx$ and $y_n = \int_0^1 x^n e^x dx$. We can write it as $\int_0^1 x^{n+1} d(e^x)$. Now, when we integrate by parts, what we get? $x^{n+1} e^x$ minus $\int_0^1 (n+1)x^n e^x dx$. Now, when we integrate by parts, what we get? $x^{n+1} e^x$ minus $(n+1) \int_0^1 x^n e^x dx$. So, we get $y_{n+1} = e - (n+1)y_n$, $n=0, 1, 2, \dots$

So, $n+1$ times x^n into e^x , now when x is equal to 1, we get this value as e and when x is equal to 0 e^0 is 1, but x^n becomes 0 because n values 0, 1, 2, 3 and so on. So, $n+1$ is greater than or equal to 1. So, we get here $e - (n+1)y_n$ where n 'th x values 1, 2, 3 and so on.

Now, we will need y_0 . y_0 can be calculated from the given equation. So, we can put here n equal to 0, 1, 2, 3 and so on. Now we will in order to calculate y_1 , we need the value of y_0 . y_0 will be calculated directly from the given formula. So, y_0 from the given formula is $\int_0^1 e^x dx$ which is equal to e^x from 0 to 1 and you know that integral of e^x is e^x . So, $e^1 - e^0$ which is equal to $e - 1$.

minus 1; so, y_0 is equal to $e - 1$. Now let us calculate y_1 from this recurrence relation..

So, put n equal to 0 putting n equal to 0 in the recurrence relation we get y_1 equal to $e - y_0$ and this is equal to $e - (e - 1)$ which is equal to 1. So, y_1 is equal to 1, again, we can calculate use the recurrence relation to calculate y_2 , y_2 equal to putting n equal to 1 y_2 equal to $e - 2y_1$ $e - 2y_1$ means $e - 2$ because y_1 is equal to 1 and y_3 . Similarly, we can calculate y_3 equal to $e - 3y_2$ because y_2 is equal to 1 and y_3 . So, 3 times y_2 and this is $e - 3$ times $e - 2$. So, this is $6 - 2e$ into e and we know that the value of e is 2.7 something. So, y_0 is greater than 0.

And then y_1 is 1. So, y_0 is greater than y_1 and y_2 is $e - 2$.

(Refer Slide Time: 05:10)

Hence from (2), we get

$$y_1 = 1, \quad y_2 = e - 2$$

$$y_3 = 6 - 2e \text{ and so on.}$$

In fact

$$\Rightarrow y_0 > y_1 > y_2 > \dots > y_n > y_{n+1} > \dots > 0$$

and also that $y_n \rightarrow 0$, as $n \rightarrow \infty$.

Since $x^n > x^{n+1}$ for $0 < x < 1$, it follows that $y_n > y_{n+1}$ for any $n=0,1,2,\dots$

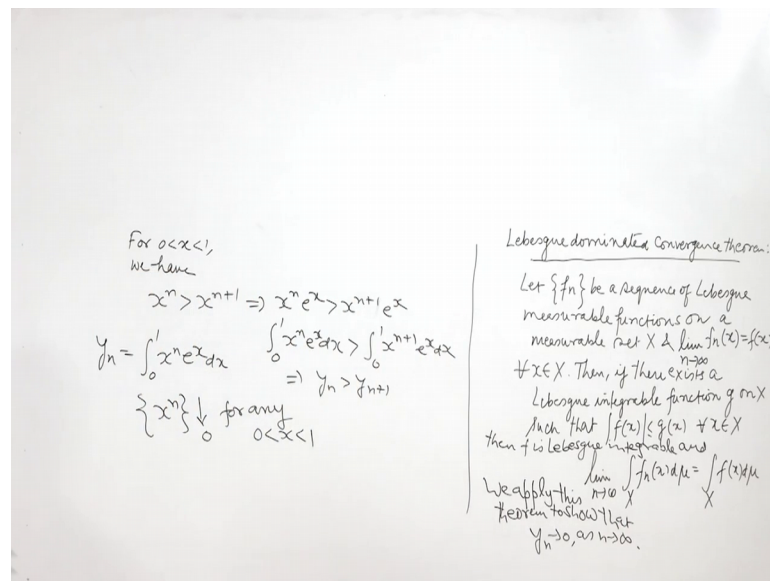

Also, the monotone sequence $\{x^n\}$ converges to 0, as $n \rightarrow \infty$, for

IIT Koorkee NPTEL ONLINE CERTIFICATION COURSE 3

So, y_1 is greater than y_2 and then you can also see that y_2 is greater than y_3 because see y_0 y_0 is greater than y_1 y_0 is $e - 1$ and $e - 1$ is greater than 1 because e is greater than 2. So, then y_1 is greater than y_2 y_1 is greater than y_2 because 1 is greater than $e - 2$ or you can say 3 is greater than $e - 2$ is less than $e - 2$ less than 3, we are making use of this. So, y_1 is greater than y_2 and y_2 is greater than y_3 and similarly, we can get y_4 greater than like this and greater than 0.

So, the y_n is a monotonically decreasing sequence positive real numbers and y_1 goes to 0 as n goes to infinity, how, let us see, how it follows we have seen that y_n is greater than y_{n+1} , y_1 is greater than y_2 , y_2 is greater than y_3 , but this will not lead us to the general inequality y_n greater than y_{n+1} . So, to see that y_n is greater than y_{n+1} , let us note that x^n is greater than x^{n+1} whenever $0 < x < 1$ ok.

(Refer Slide Time: 06:34)

So, for $0 < x < 1$, we know that we have x^n is greater than x^{n+1} and so y_n ; y_n is equal to integral 0 to 1 $x^n e^x dx$.

So, when you multiply by e^x because e^x is always positive, what we will get $x^n e^x$ is greater than $x^{n+1} e^x$ when we integrate it over the interval $0, 1$, we arrive at this which is $y_n > y_{n+1}$. So, from the fact that x^n is greater than x^{n+1} we arrive at the inequality $y_n > y_{n+1}$ for any n equal to $0, 1, 2, 3$ and so on.

Now, we also notice that the sequence x^n is a monotonically decreasing sequence of positive real numbers for any x which lies in the interval $0, 1$ open interval $0, 1$. So, this goes to 0 and for any x which lies in the open interval $0, 1$.

(Refer Slide Time: 08:18)

any fixed x in the interval $0 < x < 1$. Consequently, it follows that the monotone sequence $y_n \rightarrow 0$, as $n \rightarrow \infty$.

Suppose we calculate the iterates y_n^* in a machine with four decimal digit floating point rounded arithmetic then

$$y_2^* = 0.7183, y_3^* = 0.5634, y_4^* = 0.4647$$
$$y_5^* = 0.3948, y_6^* = 0.3495, y_7^* = 0.2718$$
$$y_8^* = 0.5439, y_9^* = -2.177, y_{10}^* = 24.49$$

•••••

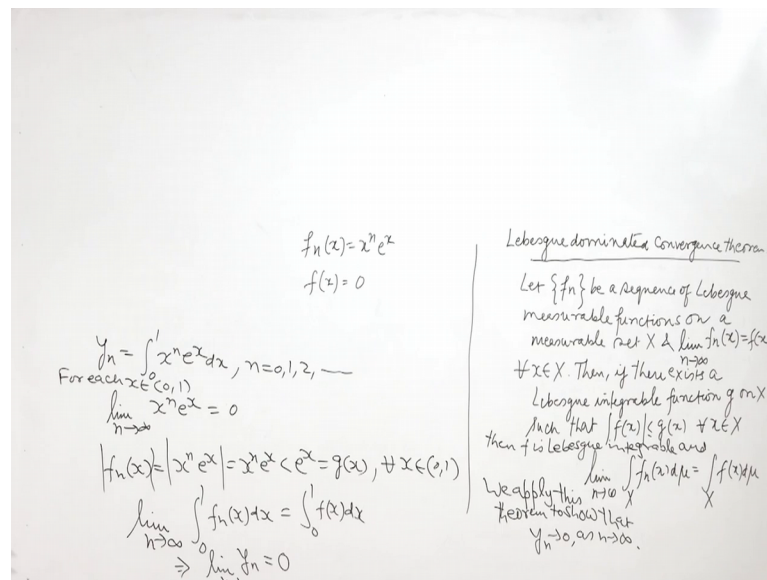

Consequently, it follows that the monotone sequence y_n goes to 0 as n goes to let us see how it follows here we will need the Lebesgue; Lebesgue dominated convergence theorem.

Let us see, what does it say this theorem let f_n be a sequence of Lebesgue measurable function un-measurable set see x we can take complex valued Lebesgue measurable functions here. So, un-measurable set x and limit n tends to infinity $f_n(x)$ is equal to $f(x)$ for every x belonging to x then if there exist a Lebesgue integration function g on x such that $|f_n(x)|$ is less than or equal to $g(x)$ for all x belonging to x , then limit n tends to infinity $\int_x f_n(x) d\mu$ is equal to $\int_x f(x) d\mu$ where μ is the major on x . Now then here, we have one more thing, then f belongs to $L^1(\mu)$ that is f is Lebesgue integrable then f is Lebesgue integrable limit n tends to infinity $\int_x f_n(x) d\mu$ is equal to $\int_x f(x) d\mu$.

Now, let us see, how we apply this theorem here we will apply this theorem to show that y_n goes to 0 as n goes to infinity. Now, let us see, what is y_n y_n is the given to the integral $\int_0^1 x^n e^{-x} dx$.

(Refer Slide Time: 12:08)

Since x to the power n into e to the power x for n equal to $0, 1, 2, 3$ and so on are continuous functions over the interval $0, 1$. So, they are Lebesgue measurable on the interval $0, 1$; the interval $0, 1$ is measurable set and limit n tends to infinity x to the power n into e to the power x goes to 0 for every x belonging to for every ϵ for each x belonging to the open interval $0, 1$ for each x belonging to the open interval $0, 1$ limit n tends to infinity x to the power n into e to the power x is equal to 0 .

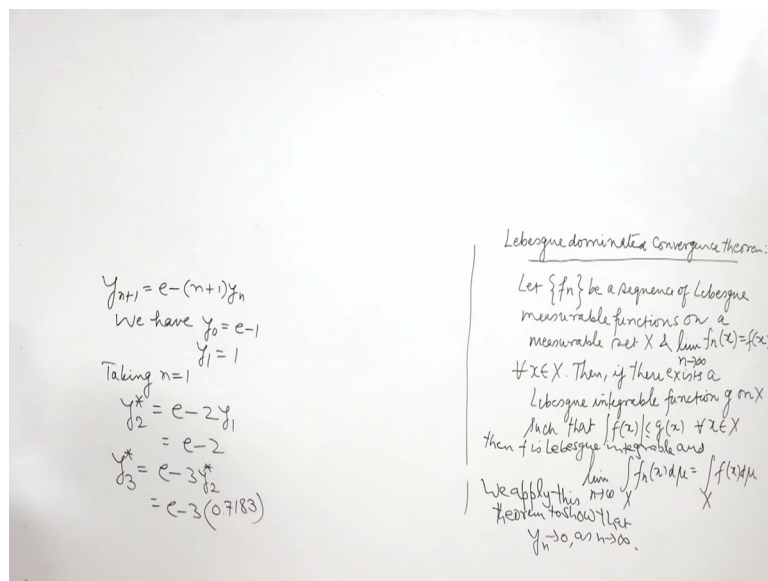

So, we have here f_n , we have as sequence as x to the power n into e to the power x on the interval $0, 1$, interval $0, 1$ limit n tends to infinity $f_n(x)$ is equal to $f(x)$. So, $f(x)$ is equal to 0 here. So, $f_n(x)$ we are taking as x to the power n into e to the power x the limiting function of x which is $f(x)$ is the 0 function now there must exist Lebesgue integrable function g on x such that $\text{mod of } f(x) \leq g(x)$, let us see, what is that function here. So, $f_n(x)$ is equal to x to the power n into e to the power x . So, $\text{mod of } f_n(x)$ is equal to $\text{mod of } x$ to the power n into e to the power x and since x belongs to the open interval $0, 1$, this is all this function and this function both are non negative functions. So, we do not have to put the modulus, we can simply write x to the power n into e to the power x .

Now, since x belongs to open interval $0, 1$ this is less than e to the power x and. So, you can take e to the power x as equal to $g(x)$. So, $g(x)$ is e to the power x in each power x is a Riemann integral function, what is Lebesgue integral and we also see that and therefore,

we can say that the function $g(x)$ is Lebesgue integrable mod of $f(x)$ is less than or equal to $g(x)$ to the power $g(x)$ for all x belonging to $[0, 1]$ and therefore, the limiting function $f(x)$ is Lebesgue integrable $f(x) = 0$ Lebesgue integrable and limit $n \rightarrow \infty$ by Lebesgue dominated convergence theorem limit $n \rightarrow \infty$ integral over $x \in [0, 1]$ $f_n(x) dx$ will become $\int_0^1 f(x) dx$ here we are on the real line this is equal to $\int_0^1 f(x) dx$. Now this is what are limit $n \rightarrow \infty$.

Now, $f_n(x)$ is $f(x)$ to the power n into e^{-x} . So, we have limit $n \rightarrow \infty$ y_n and $f(x)$ is equal to 0 integral over $[0, 1]$ of 0 function is 0 we get y_n limit of y_n as n goes to infinity equal to 0. So, y_n goes to 0 the iterates y_n which the values of i in y_n which we have calculated from the given recurrence relation they are go to 0 as n goes to infinity now suppose we calculate the iterates y_n^* in a digital computer with 4 decimal digit floating point rounded arithmetic; that means, we take β equal to n and t equal to 4, then we will get the value of y_2^* as 0.7183 if you calculate.

(Refer Slide Time: 16:31)

So, the values of y_2^* y_3^* can be calculated from the recurrence relation y_{n+1} is equal to $e^{-(n+1)} y_n$. So, when we want to calculate we are given $y_0 = e^{-1}$ and $y_1 = 1$ we have. So, when we calculate y_2 I have take n equal to 1 taking n equal to 1 we get y_2 y_2 we will denote y_2^* here. So, e^{-n} equals to 1. So, 2 times y_1 and y_1 is equal to 1. So, e^{-2} we get and e

minus 2 is equal to 0.7183 when we use 4 decimal digit floating point rounded arithmetic. So, y_2^* is 0.7183.

Now, using the value of y_2^* we can calculate y_3^* here. So, y_3^* is equal to e minus 3 times y_2^* . So, you can put e minus 3 times 0.7183, then we will get y_3^* equal to 0.5634 similarly we can calculate y_4^* , y_5^* , y_6^* , y_7^* , y_8^* . Now after y_8^* , what turns out is that y_9^* becomes negative it is minus 2.177 and y_{10}^* becomes 24.9. So, the sine starts changing the values of y_n^* starts fluctuating from here and they grow uncontrollably.

(Refer Slide Time: 18:23)

Note that the computed results are very absurd from y_8^* onwards.

While the correct iterates y_n monotonically decrease to 0, the computed iterates y_n^* oscillate from y_8^* onwards and $|y_n^*| \rightarrow \infty$, as $n \rightarrow \infty$. It is due to the fact that the round off error in the n th iterate y_n^* is multiplied by a factor $-(n+1)$ which amplifies the round off error in the resulting $(n+1)^{th}$ iterate y_{n+1}^* .

Hence the algorithm given in (2) is numerically unstable.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

So, now by the computer results we can see are very absurd from y_8^* onwards y_8^* is 0.5439, then y_9^* becomes minus 2.17. So, 1 7 7. So, the sine changes and then the next iterate is 24.49. So, they become absurd after the starting from y_8^* onwards and the correct iterates y_n , we have seen the correct iterates y_n go to 0 as n goes to infinity, the computed iterates y_n^* oscillates from y_8^* onwards and mod of y_n^* goes to infinity they grow uncontrollably as n tends to infinity.

Now this is because of the fact that the round off error in the n 'th iterate y_n^* is multiplied see this is $y_{n+1} = e^{-n-1} y_n$ whatever round off error is there in the calculation of y_n^* here that is get that gets multiplied by minus $n+1$ which amplifies the round off error in the resulting $n+1$ th iterate y_{n+1}^* and

therefore, we can say that this algorithm y_{n+1} equal to e^{-n+1} into y_n is numerically unstable.

(Refer Slide Time: 19:59)

Example: Consider the problem of computing the sequence $\{y_n \in \mathbb{R}\}$ where

$$y_n = \int_0^1 \frac{x^n}{x+7} dx$$

clearly, if $x \in (0,1)$ then $\{x^n\}$ is a monotonically decreasing sequence and $x^n \rightarrow 0$, as $n \rightarrow \infty$.

Hence,

$$\Rightarrow y_0 > y_1 > y_2 > \dots > y_n > y_{n+1} > \dots > 0$$

and also that $y_n \rightarrow 0$, as $n \rightarrow \infty$.

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 6

Let us consider one more example where we have another sequence given by y_n equal to integral 0 to 1 x^n to the power n divided by $x+7$ dx now here also x belongs to open interval $(0,1)$, then x^n is a monotonically decreasing sequence and x^n to the power n goes to 0 as n goes to infinity. So, we can see that y_n is equal to integral 0 to 1 x^n to the power n divided by $x+7$ dx .

(Refer Slide Time: 20:35)

So, $y_0 > y_1 > y_2 > \dots > y_n > y_{n+1} > \dots > 0$

$$|f_n(x)| = \frac{x^n}{x+7} < \frac{1}{7}, \forall x \in (0,1)$$

Take $f_n(x) = \frac{x^n}{x+7}$
 $\lim_{n \rightarrow \infty} f_n(x) = 0$
 So $f(x) = 0$

Let us take $g(x) = \frac{1}{7}$
 So $\lim_{n \rightarrow \infty} \int_0^1 f_n(x) dx = \int_0^1 f(x) dx$
 $\Rightarrow \lim_{n \rightarrow \infty} y_n = 0$

Lebesgue dominated convergence theorem:
 Let $\{f_n\}$ be a sequence of Lebesgue measurable functions on a measurable set X & $\lim_{n \rightarrow \infty} f_n(x) = f(x)$, $\forall x \in X$. Then, if there exists a Lebesgue integrable function g on X such that $|f_n(x)| \leq g(x)$ $\forall x \in X$, then f is Lebesgue integrable and $\lim_{n \rightarrow \infty} \int_X f_n(x) d\mu = \int_X f(x) d\mu$.
 We apply this theorem to show that $y_n \rightarrow 0$, as $n \rightarrow \infty$.

$x^n > x^{n+1}$ $\forall x \in (0,1)$
 $\Delta n=0,1,2, \dots$

$x^n > x^{n+1}$
 $\Rightarrow \frac{x^n}{x+7} > \frac{x^{n+1}}{x+7}$
 $\Rightarrow \int_0^1 \frac{x^n}{x+7} dx > \int_0^1 \frac{x^{n+1}}{x+7} dx$

So, x^n is greater than x^{n+1} for all x belonging to open interval $(0, 1)$ and n equal to $0, 1, 2, 3$ and so on. So, what do we notice that y_n is greater than y_{n+1} .

So, this implies that x^n over x^{n+1} is greater than x^{n+1} over x^{n+2} because when x belongs to open interval $(0, 1)$ x^{n+1} is positive. So, the inequality will not change and this implies $\int_0^1 x^n dx$ is greater than $\int_0^1 x^{n+1} dx$ and or we can say y_n is greater than y_{n+1} . So, y_n is a sequence of positive real numbers and it is monotonically decreasing.

Now, here also we notice that y_n goes to 0 as n goes to infinity. Now let us see how y_n goes to 0 as n goes to infinity. So, here again we will use the Lebesgue dominated convergence theorem $f_n(x)$, you take as take $f_n(x)$ equal to x^n over x^{n+1} then $f_n(x)$ are continuous functions over the open interval $(0, 1)$ open interval $(0, 1)$ is measurable set and the continuous functions are measurable. So, $f_n(x)$ are f_n is a sequence of Lebesgue measurable functions on the measurable side $(0, 1)$ and limit n tends to infinity $f_n(x)$ is equal to 0 for each x belonging to open interval $(0, 1)$ because x^n goes to 0 as n goes to infinity. So, $f(x)$ is 0 function here $f(x)$ is the 0 function and there are just we there should adjust a Lebesgue integrable function g on x such that $|f_n(x)|$ is less than or equal to $g(x)$.

So, we can see that $|f_n(x)|$ is equal to x^n divided by x^{n+1} because x^n over x^{n+1} is a non negative functions. So, we can we do not have to put mod now this is less than one by n for all x belonging to open interval $(0, 1)$. So, we can take $g(x)$ to be one by n . So, let us take $g(x)$ equal to $1/n$ which is a constant function constant function is continuous function. So, it is Riemann integrable and therefore, it is Lebesgue integrable.

So, $g(x)$ is Lebesgue integrable function thus we have found a Lebesgue integrable function $g(x)$ such that $|f_n(x)|$ is less than or equal to $g(x)$ and therefore, the function f is integrable that is this 0 function is Lebesgue integrable and the limit of $f_n(x)$ as n goes to infinity over the interval $(0, 1)$ is equal to $\int_0^1 f(x) g(x) dx$. So, limit n tends to infinity $\int_0^1 f_n(x) dx$ is equal to $\int_0^1 f(x) dx$ now $\int_0^1 f_n(x) dx$ is y_n

$f_n(x)$ is x to the power n over x plus seven. So, we get limit n tends to infinity y_n equal to $f(x)$ is a 0 function. So, we get 0. So, y_n goes to 0 as n goes to infinity using Lebesgue dominated convergence theorem.

Now, we shall discuss 2 algorithms to evaluate the value of y_n for n equal to 0, 1, 2, 3 and. So, on we shall show that one algorithm is a numerically unstable while the other algorithm is numerically stable. So, what we will do is let us see we can write the given equation like this, we have y_n equal to this is given to us. Now from this equation, we see that we can write.

(Refer Slide Time: 26:13)

Handwritten mathematical derivation:

$$y_n = \int_0^1 \frac{x^n}{x+7} dx \Rightarrow y_0 = \int_0^1 \frac{1}{x+7} dx = \left\{ \ln(x+7) \right\}_0^1 = \ln 8 - \ln 7 = \ln \frac{8}{7} = 0.1335$$

Then

$$y_n + 7y_{n-1} = \int_0^1 \left(\frac{x^n + 7x^{n-1}}{x+7} \right) dx$$

$$= \int_0^1 x^{n-1} dx = \left(\frac{x^n}{n} \right)_0^1 = \frac{1}{n}, \quad n=1, 2, \dots$$

Algorithm A

$$y_n = \frac{1}{n} - 7y_{n-1}, \quad n=1, 2, \dots$$

$\beta=10, t=4$

$$y_1 = \frac{1}{1} - 7y_0 = 0.0655$$

Numerically unstable algorithm

When we add y and n 7 times y_n minus 1, we get integral 0 to 1 x to the power n plus 7 times x to the power n minus 1 over x plus 7 $d x$ and then we can cancel x plus 7 here because x plus 7 is not equal to 0 x belongs to the open interval 0 1. So, x plus 7 is not 0. So, we have integral 0 to 1 x to the power n minus 1 $d x$ and this is equal to x to the power n divided by n . So, we get y_n plus 7 times y_n minus 1 equal to 1 by n and here n takes values starting with 1 2 3 and so on because of y_n minus 1.

Now from the, with the value of y to calculate the value of y_1 from here we need the value of y naught. So, y naught is calculated from the given equation this gives you y naught you put n equal to 0. So, 0 to 1 one over x plus 7 $d x$. So, this is equal to $\ln x$ plus 7. So, $\ln 8$ minus $\ln 7$ or $\ln 8$ by 7, we do the value of y naught, this value of y naught is then use to determine y_1 y_2 y_3 and so on.

(Refer Slide Time: 28:29)

Algorithm A: We may write

$$y_n = \frac{1}{n} - 7y_{n-1}, n = 1, 2, 3, \dots$$

Let us calculate y_n in a machine with $\beta = 10$, $t = 4$ and floating point rounded arithmetic. We have

$$y_0 = \ln \frac{8}{7} = 0.1335 \quad y_1 = 1 - 7y_0 = .0655$$
$$y_2 = \frac{1}{2} - 7y_1 = .0415 \quad y_3 = \frac{1}{3} - 7y_2 = .0428$$
$$y_4 = \frac{1}{4} - 7y_3 = -.0496 \quad y_5 = \frac{1}{5} - 7y_4 = 0.5472 \quad y_6 = \frac{1}{6} - 7y_5 = -3.664$$

  6

Let us look at algorithm A. So, in this algorithm what we do is we write y_n equal to $\frac{1}{n}$ minus $7y_{n-1}$ where n 'th x values $1, 2, 3$ and so on. So, from $y_n = \frac{1}{n} - 7y_{n-1}$ we have $y_n = \frac{1}{n} - 7(\frac{1}{n-1} - 7y_{n-2})$ and is equal to $\frac{1}{n} - \frac{7}{n-1} + 49y_{n-2}$ and so on. Now let us take β equal to 10 and t equal to 4 , then we know the value of y_0 is equal to $\ln \frac{8}{7}$ by; so, y_1 star. So, we will call it as y_1 star. y_1 star is equal to $1 - 7y_0$ and y_0 which is $\ln \frac{8}{7}$ is 0.1335 ; 0.1335 when we use t equal to 4 the value of $\ln \frac{8}{7}$ is 0.1335 . So, let us write y_1 , let us write y_1 here, let us y_1 is equal to $1 - 7y_0$ and that comes out to be 0.0655 .

So, then we calculate y_2 y_2 is equal to $\frac{1}{2} - 7y_1$, we put the value of y_1 as 0.0655 to calculate y_2 y_2 comes out to be 0.0415 , then y_3 is $\frac{1}{3} - 7y_2$ which is 0.0428 , y_4 comes out to be minus 0.0496 , y_5 is 0.5472 and y_6 is minus 3.624 . So, you see that starting with y_4 , the value of the iterate. In fact, starting with y_3 we see that the value of the y_n start fluctuating. So, this is not a numerically stable algorithm and one more, we think we see that y_2 is 0.0415 y_3 is 0.0428 . So, y_2 is y_3 is greater than y_2 .

While we have seen that the values of y_n should decrease n decrease to 0 as n goes to infinity.

(Refer Slide Time: 31:14)

Evidently, the round off errors lead to very absurd result like $y_3 > y_2$ and y_4 is negative. The computed iterates, for $n \geq 3$, oscillate and $|y_n| \rightarrow \infty$ as $n \rightarrow \infty$ while the actual iterates form a monotonically decreasing sequence which converges to zero, as $n \rightarrow \infty$.

The reason is that the round off error in each iteration is multiplied by the factor -7 , and hence the round off errors grow uncontrollably and the computed iterates diverges.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE 7

But here y_3 is greater than y_2 and starting with y_3 the values of y_n start fluctuating the round off error lead to very absurd result here and the round off errors are magnified actually because of the multiplication of minus $7 y_n$ minus one. So, whatever round off error is there in the computation of y_{n-1} that get gets multiplied by minus 7 and is therefore, amplified..

So, y_3 is greater than y_2 y_4 is negative the computed iterates for n greater than or equal to 3 is starts oscillating and the absolute value of y_n tends to infinity as n goes to infinity you can see that the numerical the numerical value of the iterates is starts increasing the y_5 is 0.5472 , y_6 is numerical value of y_6 is 3.64 . So, they go to infinity as n goes to infinity while the actual iterates form a monotonically decreasing sequence which convergence to 0 as n goes to infinity. Now as I said the reason is that the round off error in each iteration is multiplied by the factor minus 7 and therefore, the round off errors go grow uncontrollably and the computed iterates diverge. So, this algorithm is numerically unstable this is numerically unstable algorithm.

Now, let us see we will write the equation $y_{n+1} = 7y_n - 1$ equal to 1 by n and we shall see we have a stable algorithm. So, how to get this stable algorithm? So, in the algorithm B, we know that the actual iterates y_n go to 0 as n goes to infinity.

(Refer Slide Time: 33:31)

Algorithm B: Since the actual iterates $y_n \rightarrow 0$, as $n \rightarrow \infty$, we may suppose that $y_9 \approx y_{10}$.

From the relation (3), we have

$$y_{10} = \frac{1}{10} - 7y_9$$

$$\Rightarrow y_9 = \frac{1}{10} - 7y_9 \Rightarrow y_9 = 0.0125.$$

Now, proceeding backward, we use the algorithm

$$y_{n-1} = \frac{1}{7} \left(\frac{1}{n} - y_n \right), \quad n = 9, 8, 7, \dots, 1$$

10

And therefore, we may suppose that y_9 and y_{10} are approximately same. So, y_9 is approximately equal to y_{10} .

(Refer Slide Time: 33:41)

Algorithm B: $y_9 \approx y_{10}$

Proceeding backwards & using

$$y_{n-1} = \frac{1}{7} \left(\frac{1}{n} - y_n \right)$$

$$y_8 = \frac{1}{7} \left(\frac{1}{7} - y_9 \right)$$

$$= 0.0141$$

$$y_7 = \frac{1}{7} \left(\frac{1}{8} - y_8 \right)$$

$$= \frac{1}{7} \left(\frac{1}{8} - 0.0141 \right)$$

$$=$$

$y_n + 7y_{n-1} = \frac{1}{n}$

$$\Rightarrow y_{n-1} = \frac{1}{7} \left(\frac{1}{n} - y_n \right)$$

$$y_9 = \frac{1}{7} \left(\frac{1}{10} - y_{10} \right)$$

Since $y_9 \approx y_{10}$
we may write

$$y_9 = \frac{1}{7} \left(\frac{1}{10} - y_9 \right)$$

$$8y_9 = \frac{1}{10}$$

$$\text{or } y_9 = \frac{1}{80} = 0.0125$$

Now, from this relation $y_{n+7} + y_{n-1} = \frac{1}{n}$ from this, what do we notice? We notice that y_{10} is equal to $\frac{1}{10} - 7y_9$ we notice that this gives you $y_{n-1} = \frac{1}{7} \left(\frac{1}{n} - y_n \right)$.

So, y_{n-1} is equal to $\frac{1}{7} \left(\frac{1}{n} - y_n \right)$. So, y_9 is equal to $\frac{1}{7} \left(\frac{1}{10} - y_{10} \right)$. Now what we will do is since y_{10} is approximately same as y_9 .

9, we can write y_9 equal to. So, this gives you y_9 equal to $\frac{1}{7} \times \frac{1}{10} - y_9$ and so, this is how much $\frac{1}{7} \times \frac{1}{9} + y_9$. So, y_9 equal to $\frac{1}{7} \times \frac{1}{10}$ or we can say y_9 equal to $\frac{1}{70}$. So, when we assume that y_9 and y_{10} are approximately same the value of y_9 comes out to be 0.0125.

Now, what we do is we proceed backwards and use the algorithm. So, proceeding backwards and using $y_{n-1} = \frac{1}{7} \times \frac{1}{n} - y_n$, we can calculate y_8, y_7, y_6 and so on. So, y_8 if we want we put n equal to 9 here. So, y_8 equal to $\frac{1}{7} \times \frac{1}{9} - y_9$ and when we calculate y_8 from this equation. So, then y_8 comes out to be 0.0141. Now again y_7 is equal to $\frac{1}{7} \times \frac{1}{8} - y_8$ putting n equal to 8. So, y_7 we can calculate. So, $\frac{1}{7} \times \frac{1}{8} - 0.0141$ and when we obtain the value of y_7 , it comes out to be 0.158.

(Refer Slide Time: 37:40)

then we get

$$y_8 = \frac{1}{7} \left(\frac{1}{9} - y_9 \right) = 0.0141 \quad y_7 = \frac{1}{7} \left(\frac{1}{8} - y_8 \right) = 0.158$$

likewise $y_6 = 0.0182, y_5 = 0.0212, y_4 = 0.0255$
 $y_3 = 0.0321, y_2 = 0.0430, y_1 = 0.0653, y_0 = 0.1335$
 which are correct values. Thus, by rearranging the recurrence relation (3) in such a way that the round off errors do not grow uncontrollably, we get a numerical stable algorithm.

So, likewise we go and calculating the values y_6 is 0.0182, y_5 0.0212, y_4 0.0255, y_3 is 0.0321, y_2 is 0.0430, y_1 is 0.0653 and y_0 is 0.1335 which are correct values thus by rearranging the recurrence relation 3 the recurrence relation 3 is $y_n + 7 y_{n-1} = \frac{1}{n}$ in such way that the round off errors do not grow uncontrollably we get a numerically stable algorithms. So, this is a numerically stable algorithm. So, we see that one scheme or one algorithm is numerically unstable while the other algorithm is numerically stable. So, with this I would like to conclude my lecture.

Thank you very much for your attention.
