**Lecture - 42**  
**Singular value decomposition of a matrix- I**

Hello friends, welcome to this lecture, in this lecture we will discuss the very important tool in numerical linear algebra that is singular value decomposition and this here, after we call this singular value decomposition as SVD. And this SVD has a lot of very important application in various field of engineering and sciences. For example, we need it and control theory, image processing and several other field. So, let us start, what do you mean by singular value decomposition?

(Refer Slide Time: 00:58)

**Singular Value Decomposition**

The Singular Value Decomposition(SVD) can be used as an effective tool in handling several computationally sensitive computations such as:

- Rank and Rank deficiency of a matrix
- Nearness of a matrix from an immediate lower rank matrix
- Orthonormal bases and Orthogonal projections
- Solving the least square problems.

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    2

So, this singular value decomposition can be used as an effective tool in handling several computationally sensitive computation such as, rank and rank deficiency of a matrix. Sometimes it may happen that, your matrix which we are handling is having very is ill conditioned or we can say that, the lowest eigen value of a given matrix is very, very small. So, it may create problem in handling many of the calculation using this matrix and second is that, nearness of a matrix from an immediate lower rank matrix or you can say that, approximation of a matrix with an immediate lower rank matrix.

So, there this SVD is very, very useful and then, finding orthonormal bases for row space, column space and they are orthogonal complement subspaces and respective orthogonal projection. So, calculating this orthonormal bases and orthogonal projection we use SVD and also we use SVD in solving the least square problems, that all these all these problems we will discuss in coming lectures. So, let us first start what do you mean by SVD?

(Refer Slide Time: 02:18)

**Theorem 1**  
*(SVD Theorem) Let  $A$  be a real  $m \times n$  matrix with  $m \geq n$ . Then, there exist an  $m \times m$  orthogonal matrix  $U$ , and an  $n \times n$  orthogonal matrix  $V$  such that*

$$U^T AV = \begin{bmatrix} S_1 \\ 0 \end{bmatrix} = S \quad (1)$$

*is a "diagonal" rectangular matrix of order  $m \times n$ , and  $S_1 = \begin{bmatrix} \sigma_1 & & & \\ & \sigma_2 & & \\ & & \ddots & \\ & & & \sigma_n \end{bmatrix}$  is a nonsingular matrix. The diagonal elements of  $S_1$  are all nonnegative, and they can be arranged so that*

$$\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n \geq 0$$

*The number of nonzero diagonal elements of  $S_1$  equals the rank of  $A$ .*

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

So, so here, let  $A$  be a real  $m$  cross  $n$  matrix with  $m$  greater than or equal to  $n$ , then they exist an  $m$  cross  $m$  orthogonal matrix  $U$  and  $n$  cross  $n$  orthogonal matrix  $V$  such that,  $U$  transpose  $AV$  equal to  $S_1$   $0$  equal to  $S$  here,  $0$  is a matrix of appropriate size and we call this  $S_1$   $0$  as  $S$  where, we say that, it is a diagonal rectangular matrix of order  $m$  cross  $n$  and  $S_1$  we are denoting as this diagonal matrix whose, diagonal elements are  $\sigma_1$  to  $\sigma_n$  is a nonsingular matrix.

So, the diagonal element of  $S_1$  are all nonnegative and they can be arranged in a way such that,  $\sigma_1$  is greater than  $\sigma_2$  and it is greater than equal to  $\sigma_n$  greater than equal to  $0$  see the number of nonzero diagonal elements of  $S_1$  equals the rank of  $A$ . So, here we want to get this kind of theorem first of all and if you look at look at this representation  $U$  transpose  $AV$  equal to  $S$  if you remember that, if  $A$  is a square matrix and if  $A$  is a diagonalizable matrix, then we can have this kind of matrix  $P$  transpose  $AP$  equal to some  $D$  matrix, but what happen if this matrix  $A$  is not diagonalizable then, we

can utilize this SVD theorem to your nearly diagonalizable near nearly you can say that,  $U^T A V$  is a nearly diagonal matrix or we can say that, we have a diagonal rectangular matrix and we will see that, why this form is very, very important? And how to find out this capital  $U$  and capital  $V$ ?

(Refer Slide Time: 04:14)

**Proof.** Consider the  $n \times n$  square matrix  $A^T A$ . It is both symmetric and positive semi definite, and therefore its eigenvalues are all non negative. Denote the eigenvalues of  $A^T A$  by

$$\lambda_1 = \sigma_1^2, \lambda_2 = \sigma_2^2, \dots, \lambda_n = \sigma_n^2$$

Let  $\text{rank}(A) = r$ , and since  $\text{rank}(A) = \text{rank}(A^T A)$ , it follows that  $A^T A$  has  $r$  nonzero eigenvalues. Without any loss of generality, we may assume that the eigenvalues of  $A^T A$  have been ordered in a way that

$$\sigma_1^2 \geq \sigma_2^2 \geq \sigma_3^2 \geq \dots \geq \sigma_r^2 > 0, \text{ and, } \sigma_{r+1}^2 = \sigma_{r+2}^2 = \dots = \sigma_n^2 = 0$$

Since  $A^T A$  is symmetric, it is orthogonally diagonalizable. Therefore, there exists an  $n \times n$  orthogonal matrix  $V$  such that

So, let us prove this theorem. So, here consider the  $n$  cross  $n$  square matrix  $A$  transverse  $A$  now, since  $A$  is a  $n$  cross  $n$  matrix. So,  $A$  transverse  $A$  is we can define a  $n$  this is coming out to be symmetric and positive semi definite. So, it means that, it is eigenvalues are all non-negative. So, let us calculate all the eigenvalues of  $A$  transverse  $A$  call these eigenvalues as  $\sigma_1^2$  and  $\sigma_n^2$  and we are denoting as  $\lambda_1$  as  $\sigma_1^2$ ,  $\lambda_2$  as  $\sigma_2^2$ ,  $\lambda_n$  as  $\sigma_n^2$  and here, let us assume that, rank of  $A$  is some  $r$  where,  $r$  may be less than or equal to  $n$  and we already know that, rank of  $A$  is same as rank of  $A$  transverse  $A$ .

So, it means that a transverse  $A$  has a nonzero eigenvalues. So, it means that, out of these  $n$  eigenvalues only  $r$  eigenvalues are non 0 rest of all 0 0 eigen value. So, without any loss of generality we may assume that, the eigenvalues of  $A$  transverse  $A$  have been ordered in a way. So, what we try to do we try to order them order the eigenvalues of  $A$  transverse  $A$  and in a way such that,  $\sigma_1^2$  is the largest eigen value and  $\sigma_r^2$  is the smallest eigen value and rest are all is  $n$  minus  $r$  eigenvalues are 0 eigen values.

(Refer Slide Time: 06:55)

Let  $V_1 = [v_1, v_2, \dots, v_r]$ , and  $V_2 = [v_{r+1}, v_{r+2}, \dots, v_n]$

Then,

$$V_2^T A^T A V_2 = V_2^T [0, 0, \dots, 0] = 0$$

or

$$(A V_2)^T (A V_2) = 0. \quad (3)$$

From (3), it follows that

$$x^T (A V_2)^T (A V_2) x = (A V_2 x)^T (A V_2 x) = \|A V_2 x\|^2 = 0, \forall x \in \mathbb{R}^m,$$

or

$$A V_2 x = 0, \forall x \in \mathbb{R}^m$$

This shows that

$$A V_2 = 0, \text{ or } A v_i = 0, i = r + 1, r + 2, \dots, n. \quad (4)$$

NPTEL ONLINE CERTIFICATION COURSE

So now, let us write this V as V1 and V2 where, V1 consist of first r eigenvectors. So, V1 is a matrix consisting first r eigen first r columns of V and V2 consist of the remaining n minus r columns of V.

So, we can calculate that, V2 transverse A transverse A V2, which we can say that, it is nothing but A transverse A operating on V2. So, if you look at A transverse A operating on V2 means, A transverse A operating on Vr plus 1 to Vn. Now, this Vr plus 1 to Vn are the eigenvector corresponding to sigma r square sigma r plus 1 square, sigma r plus 2 whole square and sigma n square. Now, these are the eigenvector corresponding to 0 eigenvalue. So, it means that, A transverse A V2 is going to be 0.

So, it means that, A transverse A V2 is a 0 matrix 0 comma 0 comma 0 n minus r 0 are here. So, if you apply V2 transverse on this 0 matrix you will get a 0. So, it means V2 transverse A transverse A V2 is coming out to be 0, which we can written as A V2 transverse A V2 equal to 0 and here, we can say that from this we can verify that x transverse A V2 transverse A V2 x is equal to A V2 x transverse A V2 x and this is coming out to be norm of A V2 x whole square and it is coming out to be 0 because, of this equation number 3.

So, this is true for every x in Rm. So, in particular we can say that, AV2 x is equal to 0 because, if norm of any vector is 0. So, it means that that vector is nothing but a 0 vector. So, it means that AV2 x is equal to 0 for every x in Rm.

So, in particular we can take  $x$  as standard basis of  $\mathbb{R}^m$  and we can show that,  $AV_2$  is a 0 matrix. So, or you can say that,  $AV_2$  is equal to 0 means  $AV_i$  is equal to 0 where,  $i$  is running from  $r+1$  to  $n$ . So, it means that  $AV_i$  is equal to 0 for  $i$  equal to  $r+1$  to  $n$ . So now, what we have done here, we are almost able to find out our  $V$  now, we try to find out the matrix  $U$  for that, we define  $Z$  by  $\sigma_1$  to  $\sigma_r$  diagonal matrix whose diagonal elements are  $\sigma_1$  to  $\sigma_r$ .

(Refer Slide Time: 09:23)

If we define  $Z$  by

$$Z = \begin{bmatrix} \sigma_1 & & & \\ & \sigma_2 & & \\ & & \ddots & \\ & & & \sigma_r \end{bmatrix}_{r \times r},$$

then  $Z$  is clearly a nonsingular matrix. Moreover, from (2), it follows that

$$V_1^T (A^T A) V_1 = \begin{bmatrix} \sigma_1^2 & & & \\ & \sigma_2^2 & & \\ & & \ddots & \\ & & & \sigma_r^2 \end{bmatrix} = Z^2.$$

Consequently, we have

$$Z^{-1} V_1^T A^T A V_1 Z^{-1} = I \quad (5)$$

7

So, these are all nonzero eigen square root of eigenvalues of  $A$  transverse  $A$ . So, we can say that,  $Z$  is clearly a nonsingular matrix. So, from we can say that, let us calculate  $V_1$  transverse  $A$  transverse  $A V_1$ . So, if you look at what is  $V_1$  here,  $V_1$  is a matrix of consisting the first  $r$  column of  $V$  and these are eigenvectors corresponding to  $\sigma_1$  square,  $\sigma_2$  square and  $\sigma_r$  square. So, using this information we can say that,  $A$  transverse  $A V_1$  is basically  $\sigma_1$  square,  $V_1$   $\sigma_2$  square,  $V_2$  and  $\sigma_r$  square  $V_2$  and when we apply  $V_1$  transverse it is coming out to be  $A$  diagonal matrix and whose, diagonal elements are  $\sigma_1$  square,  $\sigma_2$  square up to  $\sigma_r$  square.

And if you want to write this in terms of  $Z$  then, we can say that it is nothing but  $Z$  square. So, using this representation we can further simplify this and we can say that, applying  $Z$  inverse from the left-hand side and the right-hand side we can say that, this can be re written as  $Z$  inverse  $V_1$  transverse  $A$  transverse  $A V_1 Z$  inverse equal to  $I$ . So, let

us if you look at this is a kind of this can be utilized as finding the matrix U. So, here we call this matrix  $AV_1Z^{-1}$  inverse as U. So, if you call this a  $V_1Z$  inverse as  $U^{-1}$ .

(Refer Slide Time: 11:09)

Now, we may define an  $m \times r$  matrix  $U_1$  by

$$U_1 = AV_1Z^{-1}. \quad (6)$$

From (5), we have

$$U_1^T U_1 = Z^{-1} V_1^T A^T AV_1 Z^{-1} = I$$

showing that  $u_1, u_2, \dots, u_r$  are orthonormal vectors in  $\mathbb{R}^m$ .  
Also, from (6), we have

$$u_i = \frac{1}{\sigma_i} AV_i \quad \text{for } i = 1, 2, \dots, r \quad (7)$$

Now, define a set  $\mathcal{B}_1$  by

$$\mathcal{B}_1 = \{u_1, u_2, \dots, u_r\}.$$

We claim that  $\mathcal{B}_1$  forms an orthonormal basis for the subspace  $\mathcal{R}(A)$  of  $\mathbb{R}^m$ , where  $\mathcal{R}(A)$  denotes the range or column space of  $A$ .

So, we define we define  $n \times m$  cross  $r$  matrix  $U_1$  by  $U_1$  equal to  $AV_1Z^{-1}$ . So, if you look at if we take this as  $U_1$  then, this is nothing but  $U_1$  transverse into  $U_1$  equal to  $I$  we simply say that that,  $U_1$  is an is an orthogonal matrix or we can say that  $U_1$  transverse  $U_1$  is basically  $I$  or we can say that  $U_1, U_2, \dots, U_r$  are orthonormal vectors in  $\mathbb{R}^m$ . So, columns of  $U_1$  forms an orthonormal say orthonormal set in  $\mathbb{R}^m$

So, what we have found here, is the matrix of size  $m \times r$   $U_1$  such that,  $U_1$  transverse  $U_1$  is equal to  $I$  we can say that, columns of  $U_1$  matrix which is which are  $U_1$  to  $U_r$  are orthonormal vectors in  $\mathbb{R}^m$  or if we look at we can from this  $U_1$  if you look at this from here, we can say that  $U_1, U_i$  is nothing but  $1$  upon  $\sigma_i A$  of  $V_i$ . So, here if you look at what is  $V_1, V_1$  is basically consisting of  $V_1$  to  $V_r$  eigenvectors corresponding to  $A$  transverse  $A$ . So, here we can simplify this equation number 6 and we can write it  $U_i$  equal to  $1$  upon  $\sigma_i A$  of  $V_i$  for  $i$  equal to  $1$  to  $r$ .

So, here we have started we have defined this capital  $U_1$  with the help of matrix  $Z$ , but if you directly if you can you can directly define your  $U_1$  from this from the matrix  $V_1$  and we can say that  $U_1$  is nothing but  $1$  upon  $\sigma_i A$  of  $V_i$  where,  $i$  is running from  $1$  to  $r$ . So, we can start defining our matrix  $U_1$  from this point also, but anyway this is quite convenient if you define your  $U_1$  in terms of  $Z$ . So, here  $U_i$  is  $1$  upon  $\sigma_i A$  of  $V_i$

for  $i$  equal to 1 to  $r$ . Now, if you look at if you form the set using these  $U_i$ . So, we have a set  $B_1$  consisting  $r$  vectors defined as equation number 7 and we say that, this  $B_1$  forms an orthonormal basis for the subspace  $\mathcal{R}$  of  $A$  of  $\mathbb{R}^m$ .

Now, for that please observe that these  $U_1$  to  $U_r$  are all orthonormal vectors in  $\mathbb{R}^m$ . So, it means that, if we can prove that range space of  $A$  is having a dimension  $r$  then we can say that,  $B_1$  is an orthonormal basis for this subspace  $\mathcal{R}$  of  $A$  where,  $\mathcal{R}$  of  $A$  denotes the range or column space of  $A$ .

(Refer Slide Time: 14:22)

By (7), it is immediate that  $B_1 \subseteq \mathcal{R}(A)$ . We have seen that  $B_1$  consists of  $r$  orthonormal vectors. Since  $A$  has rank  $r$ , the subspace  $\mathcal{R}(A)$  has dimension  $r$ . Hence,  $B_1$  is an orthonormal basis for  $\mathcal{R}(A)$ .

As

$$\mathbb{R}^m = \mathcal{R}(A) \oplus \mathcal{N}(A^T)$$

where  $\mathcal{N}(A^T)$  denotes the null space of  $A^T$ . Thus  $\mathcal{N}(A^T)$  has dimension  $m - r$ . Hence, we can easily find an orthonormal basis

$$B_2 = \{u_{r+1}, u_{r+2}, \dots, u_m\},$$

for the subspace  $\mathcal{N}(A^T)$  of  $\mathbb{R}^m$ . Now, define an  $m \times (m - r)$  matrix  $U_2$  by

$$U_2 = [u_{r+1}, u_{r+2}, \dots, u_m]$$

Finally, we define an  $m \times m$  matrix  $U$  by

$$U = [U_1, U_2].$$

So, here we can say that,  $B_1$  is subset of  $\mathcal{R}$  of  $A$ , why  $B_1$  is subset of  $\mathcal{R}$  of  $A$ ? Because, if you look at the equation number 7, 7 says that  $U_i$  is nothing but  $\frac{1}{\|A v_i\|} A v_i$ . So, here this implies that, this  $U_i$  belongs to the range space of matrix  $A$ . So, it means that, all this  $U_1$  to  $U_r$  belongs to the range space of  $A$ . So, we have seen that  $B_1$  consist of  $r$  orthonormal vectors. So, since  $A$  has rank  $r$  it means subspace  $\mathcal{R}$  of  $A$  has dimension of  $r$ , why? because, range space of  $A$  is basically nothing but column space of  $A$ . Now, the column space of  $A$  has dimension  $n$ .

So, it means that range space of  $A$  has dimension  $r$ . Now, since  $A$  has rank  $r$  the subspace  $\mathcal{R}$  of  $A$  has dimension  $r$  and we can say that,  $B_1$  is basically a linearly independent because, it is orthonormal set of vector. So, we can say that,  $B_1$  is a linearly independent set of vectors whose, dimension is basically  $r$ .

So, we can say that, this  $B_1$  generate a subspace of dimension  $r$  and range space of  $A$  has dimension  $r$ . So, it means that,  $B_1$  generate the range space of  $A$  or we can say that,  $B_1$  is an orthonormal bases for this range space of  $A$ . Now, we already know that,  $\mathbb{R}^m$  can be written as range space of  $A$  null space of  $A$  transverse and. So, here we can say that, what is null space of  $A$  transverse? Null space of  $A$  transverse denote the null space of  $A$  transverse.

Now, we can say that by (Refer Time: 16:12) theorem here, the null space of  $A$  transverse (Refer Time: 16:15) has dimension  $m$  minus  $r$ . So now, we can do here, we have the basis for this range space of  $A$  now, and we want to find out say basis for  $\mathbb{R}^m$ . So, we can extend the basis of range space of  $A$  to the basis of  $\mathbb{R}^m$  and we can find out the vectors  $U_{r+1}$  to  $U_m$  and we if we ortho normalize it using gram (Refer Time: 16:42) organization process. So, we can say that, we can easily find an orthonormal basis  $B_2$  for the subspace of null space of  $A$  transverse of  $\mathbb{R}^m$ .

So here, with the help of this orthonormal basis, which is the orthonormal basis of null space of  $A$  transverse we can define the matrix  $U_2$  consisting of these  $n - m$  minus  $r$  column vectors, and we write  $U_2$  as  $U_{r+1}$ ,  $U_{r+2}$  and  $U_m$ . And with  $U_1$  and  $U_2$  we can define an  $m$  cross  $m$  matrix  $U$  by  $U$  is equal to  $U_1$  comma  $U_2$ . So, it means that the first  $r$  columns are coming from  $U_1$  and the remaining  $m - r$  columns are coming from  $U_2$ . So, we claim that, this  $U$  is the desired matrix  $m$ .

(Refer Slide Time: 17:35)

Since the columns of  $U$  form an orthonormal basis for  $\mathbb{R}^m$ ,  $U$  is an  $m \times m$  orthogonal matrix.  
Now, we have

$$U^T A V = \begin{bmatrix} U_1^T \\ U_2^T \end{bmatrix} A [ V_1, V_2 ] = \begin{bmatrix} U_1^T A V_1 & U_1^T A V_2 \\ U_2^T A V_1 & U_2^T A V_2 \end{bmatrix} \quad (8)$$

Using (5) and (6), we have

$$U_1^T A V_1 = (Z^{-1} V_1^T A^T)(A V_1) = Z \quad (9)$$

Using (4), we have

$$U_1^T (A V_2) = U_1^T(0) = 0 \quad \text{and} \quad U_2^T (A V_2) = U_2^T(0) = 0 \quad (10)$$

\*

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    10

So, here with this  $U$  we simply say that, since the columns of  $U$  forms an orthonormal basis of  $\mathbb{R}^m$ . So, we can say that, these columns of  $U_1$  and columns of  $U_2$  are basically orthogonal to each other and we say that, this  $U$  forms an orthonormal matrix of size  $m$  cross  $m$ . So, we want to calculate this  $U$  transverse  $AV$ . So, writing the expression for  $U$  transverse it is nothing but,  $U_1$  transverse,  $U_2$  transverse,  $A$  and  $V$  can be written as  $V_1$  and  $V_2$ . So, when you simplify it is coming out to be this block matrix and whose blocks are given as  $U_1$  transverse  $AV_1U_1$  transverse,  $A V_2 U_2$ transverse,  $A V_1$ and  $U_2$ ah transverse  $A V_2$ .

So, to calculate these blocks let us start with this  $U_1$  transverse  $AV_1$ . So, here  $U_1$  transverse a  $V_1$  is what using the expression for  $U_1$ ,  $U_1$ is defined as  $Z$  inverse  $V_1$  transverse  $A$  transverse  $A V_1$ and if you look at this  $V_1$  transverse  $A$  transverse  $A V_1$  is nothing but, your  $Z$  square we have already defined this as here. So, here we have defined  $V_1$  transverse  $A$  transverse  $A V_1$  as  $Z$  square. So, using this expression we can simply say that,  $Z$  inverse and this is your  $Z$  square.

So, we can say that it is  $Z$ . So, the first block is coming out to be  $Z$  here. Now, now let us we have already calculated that, this quantity  $A V_2$  is a 0-matrix for that, if you look at here we here we have proved that,  $A$  of  $V_2$  is equal to 0. So, using this  $A V_2$  is a 0 matrix we can say that,  $U_1$  transverse  $AV_2$  is basically  $U_1$  transverse applying on 0 matrix, which is coming out to be 0. So, this implies that, this block matrix is nothing but, a 0-block matrix similarly we can calculate  $U_2$  transverse  $A V_2$  because here, also we can say that since  $AV_2$  is a 0 matrix. So, operating  $U_2$  transverse on  $A V_2$  it is also coming out to be 0 matrix.

So, we here we can say that, this is  $Z$  this is 0 this is 0. Now, let us calculate this quantity  $U_2$  transverse  $A$  of  $V_1$ .

(Refer Slide Time: 19:53)

Using (6) and the fact that  $U$  is an orthogonal matrix, we have

$$U_2^T AV_1 = U_2^T U_1 Z = 0Z = 0 \quad (11)$$

Substituting (9),(10) and (11) into (8), we have

$$U^T AV = \begin{bmatrix} Z & 0 \\ 0 & 0 \end{bmatrix} = S \quad (12)$$

This completes the proof.

11

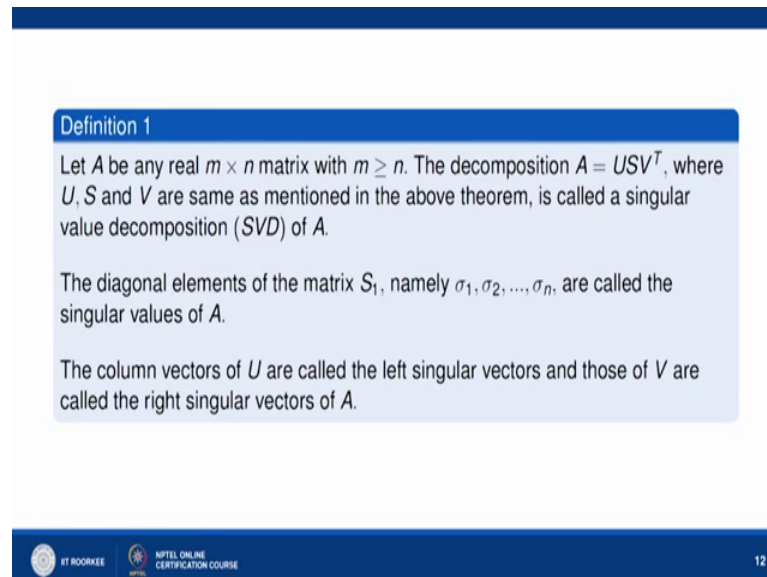

So, you look at  $U_2$  transpose  $AV_1$ . So, here we are using the here, what is the expression for  $U_1$ ? So, here  $A$  of  $V_1$  can be written as  $U_1$  of  $Z$ , how we can write it? If you look at the equation number 4 here. So, here we can say that here, equation number 6 basically  $U_1$  is equal to  $A V_1 Z$  inverse. So, we can apply  $Z$  here. So, you can say that  $U_1 Z$  is equal to  $AV_1$ . So, using the expression 6 we can write the last here that,  $U_2$  transpose  $AV_1$  and in place of a  $V_1$  we are writing  $U_1 Z$  and you can say that, this is nothing but  $U_2$  transpose  $U_1$  now,  $U_2$  transpose  $U_1$  is basically 0, why?

Because, the columns of  $U$  and columns of  $U_1$  are orthogonal to each other. So, here because, of orthogonality of matrix  $U$  this is coming out to be 0 operating on  $Z$  and it is coming out to be 0. So,  $U_2$  transpose  $AV_1$  is also coming out to be 0. So, it means that here, in equation number 8 this is coming out to be 0 because, of  $AV_2$  and this is coming out 0 because, of a  $V_2$  and here we have utilized the equation number 6 that,  $AV_1$  is equal to  $U_1 Z$ .

So, again we can say that,  $U$  transpose  $AV$  is coming out to be this matrix  $Z \ 0 \ 0$  where,  $Z$  is basically diagonal matrix consisting the diagonal entries as  $\sigma_1$  to  $\sigma_r$  here, and we call this block matrix as  $S$  and we say that,  $U$  transpose  $AV$  is  $S$  and we say that, this is the required thing we wanted to prove if you look at what is the theorem we wanted to prove? We wanted to have  $U$  transpose  $AV$  equal to  $S$  here,  $S$  is having this  $\sigma_1$  comma 0 here, we have denoted this  $\sigma_1$  as  $Z$ . So,  $Z$  is basically  $\sigma_1$  to  $\sigma_n$  here,

in this case our  $n$  is coming out to be  $r$ . So, here we have proved that,  $A$  can be decomposed as  $U$  transverse  $AV$  equal to  $S$ . Now, with the help of this decomposition we can find out we can define, what is singular value decomposition?

(Refer Slide Time: 22:14)

**Definition 1**

Let  $A$  be any real  $m \times n$  matrix with  $m \geq n$ . The decomposition  $A = USV^T$ , where  $U$ ,  $S$  and  $V$  are same as mentioned in the above theorem, is called a singular value decomposition (SVD) of  $A$ .

The diagonal elements of the matrix  $S$ , namely  $\sigma_1, \sigma_2, \dots, \sigma_n$ , are called the singular values of  $A$ .

The column vectors of  $U$  are called the left singular vectors and those of  $V$  are called the right singular vectors of  $A$ .

IT ROOKIE MPTEL ONLINE CERTIFICATION COURSE 12

So, let  $A$  be any real  $m$  cross  $n$  matrix with  $m$  is greater than or equal to  $n$  the decomposition  $A$ , which is given as  $USV$  transverse. So, we have  $U$  transverse  $AV$  equal to  $S$  and since,  $U$  and  $V$  are orthogonal matrix we can write this as a as  $USV$  transverse which is we are writing here.

So, it means that where,  $U$ ,  $S$  and  $V$  are same as mentioned in the above theorem is called a singular value decomposition of  $A$ . So, it means that,  $A$  written as  $USV$  transverse is known as singular value decomposition of  $A$  here, and the diagonal element of the matrix  $S$  namely  $\sigma_1$  to  $\sigma_n$  are called the singular values of  $A$ . The column vectors of  $U$  are called the left singular vectors and those of  $V$  are called the right singular vectors of  $A$ .

So, here we also define what is left singular vectors and right singular vectors of  $A$ . So, you can say column vectors of  $U$  are left singular vectors and columns of  $V$  are known as right singular vector vectors of  $A$ . We will try to see why we call this as left singular vectors or right singular vectors and because, of this thing that  $\sigma_1$  to  $\sigma_n$  are called singular values of  $A$  we say that, this decomposition of  $A$  is known as singular value decomposition of  $A$ .

(Refer Slide Time: 23:43)

**Remark 1**

Suppose that  $A$  is any real  $m \times n$  matrix with  $m < n$ . Then the SVD of  $A$  is defined by SVD of  $A^T$ . Since, for  $A_{n \times m}^T$ , and  $n > m$ , so, we can find  $\tilde{U}$ , and  $\tilde{V}$  such that

$$\tilde{U}^T A^T \tilde{V}^T = \tilde{S} = \begin{bmatrix} \tilde{S}_1 \\ 0 \end{bmatrix}.$$

Where  $\tilde{S} = \text{diag}(\sigma_1, \sigma_2, \dots, \sigma_n)$ . Thus, the SVD of  $A^T$  is given by  $A^T = \tilde{U} \tilde{S} \tilde{V}^T$ .

Now, we may find SVD for the matrix  $A$  as follows:  
 Define

$$U = \tilde{V}, S = \tilde{S}^T \text{ and, } V = \tilde{U}^T,$$

we see that SVD of  $A$  is given by  $A = USV^T$ , where  $S = \begin{bmatrix} S_1 & 0 \end{bmatrix}$ .

13

Now, remark 1. So, here we say that we have given the theorem for any real matrix  $m$  cross  $n$  where,  $m$  is greater than or equal to  $n$ , but what happen that if we have  $A$  matrix  $A$  of the size  $m$  cross  $n$  and  $m$  is strictly less than  $n$ . So, in this case, how we can say that how we can obtain the SVD.

So, if you look at in this case when  $A$  is any real  $m$  cross  $n$  matrix with  $m$  is less than  $n$  we can say that, SVD of  $A$  is defined by SVD of  $A$  transverse. Now, what is a transverse? So, if you define  $A$  transverse  $A$  transverse is of size  $n$  cross  $m$  and  $n$  is greater than equal to  $m$ . So, for this our theorem will be applied and we can find out  $\tilde{U}$  and  $\tilde{V}$  orthogonal matrixes of appropriate size such that,  $\tilde{U}^T A^T \tilde{V}^T$  can be written as  $\tilde{S}$  where,  $\tilde{S}$  is  $\begin{bmatrix} S_1 & 0 \end{bmatrix}$  where,  $S_1$  is the diagonal matrix consisting the singular values  $\sigma_1$  to  $\sigma_n$  thus, the SVD of  $A$  transverse is given by  $A^T = \tilde{U} \tilde{S} \tilde{V}^T$ .

Now here, we can apply the transverse of this whole expression and we can say that, if you take the transverse of the whole expression what will have we define  $U$  as  $\tilde{V}$   $S$  as  $\tilde{S}^T$  and  $V$  as  $\tilde{U}^T$  and from this we can say that, taking the transverse of the whole expression we can say that,  $A$  can be written as  $USV^T$  where,  $U$  is  $\tilde{V}$ ,  $S$  as  $\tilde{S}^T$  and  $V$  as  $\tilde{U}^T$  and here,  $S$  is what  $S$  is given by this matrix  $\begin{bmatrix} S_1 & 0 \end{bmatrix}$ .

So, it means that whether it is a any  $m$  cross  $n$  matrix whether,  $m$  is greater than or equal to  $n$  or  $m$  is less than  $n$  we can always find out the singular value decomposition of a matrix  $A$ . So, without loss of generality we can always find out SVD by assuming that, your number of rows are bigger than number of columns here.

(Refer Slide Time: 26:07)

**Remark 2**  
*Let  $A$  is any real  $m \times n$  matrix with  $m \geq n$ . If  $A$  has rank  $r$ , then  $A$  has  $r$  positive singular values denoted by  $\sigma_1, \sigma_2, \dots, \sigma_r$ . Also, since  $U$  is an  $m \times m$  orthogonal matrix, the left singular vectors of  $A$ , namely  $u_1, u_2, \dots, u_m$  form an orthonormal basis for  $\mathbb{R}^m$ . Similarly, since  $V$  is an  $n \times n$  orthogonal matrix, the right singular vectors of  $A$ , namely  $v_1, v_2, \dots, v_n$  form an orthonormal basis for  $\mathbb{R}^n$ .*

**Remark 3**  
*Let  $A$  is any real  $m \times n$  matrix with  $m \geq n$ . The singular values of  $A$  are the non negative square-roots of the eigenvalues of  $A^T A$  in nonincreasing order. Thus, the singular values of  $A$  are unique. However, the singular vectors of  $A$  may not be unique.*

FT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    14

So now, let us consider this remark 2, remark 2 says that let  $A$  is any real  $m$  cross  $n$  matrix with  $m$  greater than equal to  $n$  and if  $A$  has rank  $r$  then  $A$  has  $r$  positive singular values denoted by  $\sigma_1$  to  $\sigma_r$  and here, if you remember we have we are able to find out this matrix  $U$  consisting  $m$  orthonormal vectors and we can say that here,  $U$  is an  $m$  cross  $m$  orthogonal matrix, which we are defined as left singular values of left left singular left eigenvectors of  $A$  namely  $U_1$  to  $U_m$ . And this will form an orthonormal basis for  $\mathbb{R}^m$  similarly,  $V$  is an  $n$  cross  $n$  orthogonal matrix and we call this as right singular vectors of  $A$  and which are namely  $V_1$  to  $V_n$  and this will form an orthonormal basis of  $\mathbb{R}^n$ .

So, what we have is that, if we have a singular value decomposition of  $A$  as  $U \Sigma V^T$  then, columns of  $U$  will form a orthonormal basis for  $\mathbb{R}^m$  and columns of  $V$  will form an orthonormal basis for  $\mathbb{R}^n$ . So, with the help of SVD we can find out say orthonormal basis for domain space and codomain space now, coming out to coming to remark 3. So, here let  $A$  is any real  $m$  cross  $n$  matrix with  $m$  greater than equal to  $n$ , the singular values of  $A$  are the nonnegative square roots of the eigenvalues of  $A^T A$ .

in non-increasing order. So, we can say that singular values are going to be unique, but the singular vectors of a may not be unique the we can say like this, that if you look at A transverse A and since it is symmetric non semi definite matrix we can say that, if in the case of repeated eigenvalues then, the corresponding eigenvectors can be taken as any linearly independent vectors which can spend the eigenspace.

So, here basis since basis of any vector space is not unique. So, we can say that basis spanning the eigenspace is also not unique and we can say that your V matrix is not unique and we can say that, the singular vectors of a may not be unique because, U is very much related to capital U is very much related to V. So, here we can say that this singular vectors of a may not be unique. So, it means that singular values are unique, but not the singular vectors.

(Refer Slide Time: 29:06)

**Remark 4**

*It is important to understand the geometric interpretation of above theorem. Given any real  $m \times n$  matrix  $A$  with  $m \geq n$ , consider the associated linear mapping  $T_A: \mathbb{R}^n \rightarrow \mathbb{R}^m$  defined by  $y = T_A(x) = Ax$ . Then, we choose an orthonormal basis for  $\mathbb{R}^n$  (namely the columns of  $V$ ) and an orthonormal basis for  $\mathbb{R}^m$  (namely the columns of  $U$ ) such that  $T_A$  is diagonal in the new coordinates, i.e.  $T_A$  maps a vector of the form*

$$x = \sum_{i=1}^n \beta_i v_i$$

*into*

$$y = \sum_{i=1}^n \sigma_i \beta_i u_i$$

*In other words, any matrix  $A$  is diagonal, if we choose appropriate orthonormal bases for the domain and range of the associated linear mapping  $T_A$ .*

So now, let us coming out to be remark 4, which discuss the geometric interpretation of the S singular value decomposition theorem and it says that, given any real m cross n matrix A with m greater than equal to n it is by default we are assuming all the time consider the associated linear mapping TA, which is map which map from Rn to Rm and is defined as y equal to Tax, which is given as A of x where, A represent the matrix representation of this linear mapping T of A and we can choose an orthonormal basis for R n and it is what it is namely the columns of V and an orthonormal basis for Rm again it is the columns of U we can use we can choose the columns of U such that, T of A

diagonal in the new coordinates, that implies what that if you take any vector in  $\mathbb{R}^n$  ah, which can be written as  $\sum_{i=1}^n \beta_i V_i$ .

Then our claim is that, its image is going to be  $y$ , which is which has representation  $\sum_{i=1}^n \beta_i U_i$  and if you look at how we are here that, if you operate your  $A$  on this  $x$  then,  $A$  of  $x$  is going to be what  $\sum_{i=1}^n \beta_i A$  of  $V_i$  now, what is  $A$  of  $V_i$ ?  $A$  of  $V_i$  is given as  $\sigma_i U_i$  and this is how we define our  $U_i$ . So, we say that in other words any matrix  $A$  is diagonal if we choose appropriate orthonormal basis for the domain and range of the associated linear mapping  $T$  of  $A$ . So, earlier this representation is we know in terms of diagonalizable square matrix, but with the help of this singular value decomposition theorem, we can extend the similar kind of notation for any rectangular matrix of size  $m$  cross  $n$ . So, here I will stop this discussion.

So, in today's lecture what we have done we have done we have found the singular value decomposition of any real  $m$  cross  $n$  matrix where,  $m$  is greater than equal to  $n$  and we have seen how to find out the component of the singular value decomposition, that is how to find out capital  $U$  and how to find out capital  $V$  and how to find out the singular values of  $S$ , and will end here this discussion.

In next lecture we will try to take some example and try to find out how we can find out this  $U$   $S$  and  $V$ . So, thank you for listening us we will meet in a next lecture.

Thank you.
